The value of M or P may be obtained by the planimeter, or a transparent straight-edge may be laid parallel to the x axis and at such a distance from it that the areas included between the straight-edge and the curve will be about equally distributed above and below the straight-edge. This can be done by eye, involving an error of less than 1 ft. It gives the average ordinate of the curve, which, when multiplied by the station interval under consideration, gives the required area. The latter method is preferred. It is accurate enough and much quicker. In either case, all negative cuts and fills are taken as zero. Thus ee′, gg′, kk′ show graphically the average width of cut sections over the grades —4.6%, —0.36% and +4.8%, respectively, while ff′, hh′ and ll′ give the corresponding width of fill sections.

If a change of elevation of more than 1 ft. is made at any point, then the above method of determining the resulting change in yardage becomes very approximate, because the change in the trace curve itself becomes appreciable.

6. The ideal trace curve would be two lines parallel to the x axis.

FIG. 6. METHOD OF APPLYING THE TRACE CURVE TO AN ACTUAL ROAD BALANCE

From the above statements it is evident that the trace curve not only indicates the efficiency of balance, but also affords a rough means of rebalancing a road wherever the curve indicates the need of so doing; and it gives the approximate yardage to be saved thereby, without reference to the cross-sections.

Application of Method to an Actual Case

The trace curve shown in Fig. 6 indicates a fairly satisfactory arrangement of grade, and the road is now being built on this design. It may be used, however, to illustrate the method of procedure in case the curve indicated the need of rebalancing.

By using the transparent straight-edge, as described above, the lines ee′, ff′, gg′, hh′, kk′ and ll′ were obtained, showing the following approximate average widths of cut and fill over the lengths of the various proposed grades:

From Station	To Station	Proposed Grade	Average Width of Cut	Average Width of Fill
66+83	68+68	—4.6%	19	22
68+68	76+13	—0.36%	23	12
76+13	82+34	+4 8%	21	19

Here the value of n for the —0.36% grade is lower than that for the +4.8% grade—for the former $n = \frac{12}{23}$ and for the latter $n = \frac{19}{12}$. Hence, for an economical balance, the —0.36% grade should be raised and the +4.8% grade lowered an amount sufficient to restore the balance. With side slopes of 1 on $1\frac{1}{2}$ and level ground a change of elevation of 0.5 ft. will change cut and fill trace curves 1.5 ft. each.

Try, therefore, raising the —0.36% grade 0.5 ft. The calculation of the net saving in cut would then be:

Cut eliminated on the —0.36% grade would equal the product of the amount of the raise, the average width of cut and the length of the section raised, or

$$0.5 \times 23 \times 745 = 8568 \text{ cu.ft.} \quad (1)$$

Likewise, the fill introduced would equal

$$0.5 \times 12 \times 745 = 4470 \text{ cu.ft.} \quad (2)$$

In order to restore the balance ratio of **1.25**, the +4.8% grade must now be lowered to introduce cut equivalent to

$$8568 + (1.25 \times 4470) = 14{,}155 \text{ cu.ft.}$$

Lowering this grade 0.5 ft. will introduce cut equal to

$$0.5 \times 21 \times 621 = 6520 \text{ cu.ft.} \quad (3)$$

and eliminate fill equal to

$$0.5 \times 19 \times 621 = 5900 \text{ cu.ft.} \quad (4)$$

or introduce equivalent cut of

$$6520 + (1.25 \times 5900) = 13{,}895 \text{ cu.ft.}$$

To introduce 14,155 cu.ft. of equivalent cut, therefore, lower the —4.8% grade by

$$\left(\frac{14{,}155}{13{,}895} \times 0.5\right) = 0.51 \text{ ft.}$$

Substituting 0.51 in (3) and (4) above, the cut introduced is 6651 cu.ft. and the fill eliminated is 6018 cu.ft., and, comparing with (1) and (2), a net saving in cut of 1917 cu.ft. and in fill of 1548 cu.ft. is obtained.

If preferred, the following formula may be used instead of the above method. It may be easily derived by substituting the proper symbols in the analysis and applying numerical values for the above case.

$$S = xl_1\left(c_1 - c_2\frac{c_1 + bf_1}{c_2 + bf_2}\right)$$

where

S = net saving in cut (cu.ft.);
x = amount first grade is raised (ft.) = 0.5;
l_1 = length of first grade (ft.) = 745;
c_1 = average width of cut over first grade (ft.) = 23;
f_1 = average width of fill over first grade (ft.) = 12;
c_2 = average width of cut over second grade (ft.) = 21;
f_2 = average width of fill over second grade (ft.) = 19;
b = balance ratio = 1.25;

giving S = 1926 cu.ft., which checks substantially with the other method. The total excavation for this balance happens to be 115,284 cu.ft. and the embankment 90,696. So the maximum possible saving is only about $1\frac{1}{2}$%, and it would hardly pay to make the revision.

Thoughts on the Engineer's Relation To the Community

W. H. Finley, president and former chief engineer of the Chicago & North Western R. R., and president of the American Association of Engineers, spoke informally to an open meeting of engineers at New York Feb. 10. Ranging over the whole field of professional questions, he spoke of public service, of the engineer's backwardness in taking up his responsibilities to the community, of progressing through association, of the need for working upward from the bottom rather than down from the top in welding together the engineering profession, and of establishing the engineer on a recognized plane. Random extracts from the address are printed here as separate paragraphs. They add to the stock of thought on the development of the engineering profession.—Editor.

There is probably no profession of trained and educated men that has had such a rapid development and expansion as the engineer's. Our technical schools are now turning out engineers in shoals, almost, and I am afraid that as a profession they have hardly found themselves yet. They have lacked something in organization.

I have been quite surprised in looking up statistics to find, of the great number of engineers in the United States, how few of them belong to any engineering organization. It is really deplorable, because they need association. Take the vast body of young men coming out every year; they need encouragement, they need help. They must not think that the engineers after they attain some prominence in their profession forget the coming man, and the young man, and the man who has not yet made himself felt.

Strangers Among Their Fellow Men

Although we have so many engineers—and the number is growing constantly—yet they are very little known among their fellow men. They have always been the silent workers. They have not been very good ad-

vertisers. But a certain amount of advertising never hurt anybody. In the earlier years we suffered from the belief of the older professions that advertising is unethical, but I think the engineer has outgrown that. A certain amount of advertising is good for the engineer, good for the community, and won't hurt him one bit.

The only thing is, we need some better way of defining an engineer. He has apparently no legal standing at all. Any one can hang out a shingle and practice engineering. That belief is wrong, and something should be done to correct it. There should be some way to define an engineer and some way to establish the fact that he is competent to practice his profession. The community needs it, and it is the duty of every engineer to give consideration to that fact.

Licensing on Broad Lines

It is a question in my own mind just what sort of license law engineers should have. I believe that they should be licensed not as specialists but on a broad ground, as in the medical profession or the legal profession. When a man passes a bar examination he doesn't pass it as an expert in corporation law or in criminal law; he passes it as a lawyer, having received the necessary fundamental training so that he can specialize afterward. It is the same way in medicine. When a man receives his diploma it does not say that he is an expert on the eye, ear and nose, or any other part of the human anatomy; it simply says that he has received the training and pursued the necessary studies to fit him to practice medicine, and he can afterward specialize in any branch that he chooses. It is a question with me whether engineers should not also be licensed on broad lines rather than on the narrow lines of any specialty.

Local Problems Before Engineers

We have a deplorable condition all over the United States, as far as engineers are concerned. We have it in the West and we have it in the City of Chicago. No doubt you have it here in New York. My attention not long ago was called to a condition in Chicago in the classified service of the city, containing a large number of engineers. For twenty years they haven't had an increase in salary, nothing more than the passage from one grade to another, with the result that the mechanic, the artisan and the tradesman that they direct are getting more than the engineer in charge of the work. That condition should not exist.

They have in that city a position of smoke inspector. The act creating it says it should be filled by a mechanical engineer; they appointed a dentist to the job. Not long ago they were to appoint a mechanical engineer in charge of a municipal plant; I think it is a plant costing about $2,000,000, and the act creating the position in the classified service said it should be a mechanical engineer's. They held a civil-service examination for it, but changed the classification so that any one could take the examination, with the result that a politician got the job, insead of a mechanical engineer.

That is all our concern. It is the concern of every engineer, and he should wake up to it. He should take an interest in his home affairs and in his civic affairs. He should see that these things are run the way they should be, and that positions which call for technical training and call for engineering skill are filled by engineers and not by politicians.

Responsibilities in the Labor Problem

It has always been my hope that the engineer would be the man to solve the questions of capital and labor, and successfully bridge the chasm between the two. There isn't a man who should understand labor better than the engineer, because labor is merely one of the tools he uses to carry out his ideas. It is just as necessary to him as the slide rule; his plans and his hopes and his promises could not be accomplished unless he employed labor.

No trained, educated, professional man comes closer to labor than the engineer. He certainly should understand labor better than any other man. I regret to say that apparently he does not.

In all the work that you handle, all the men that you direct, you should get closer to them. You should know their hopes and their aspirations and their desires, because they are making up this country just the same as you. I have never in my experience failed to find that the human touch meant more than anything else.

The human touch and the human feeling—it's the thing that's going to be necessary in the new condition that is coming over society. It is coming. We have got to have a better understanding with each other, and of each other and our fellow man, whoever he may be. As long as he is associated with us, and is a part of the force that is helping us to build up the country, we should understand him. We should analyze him and we should know him better than we do.

The engineer should really understand labor, should have been the leader of labor, the man whom they would look for advice and for help. But, I must say again, unfortunately the engineer has not been that man. Whether he has been afraid of himself or whatever the reason, he has not established that close relation with the men he was working with or that were working for him that he should have established.

Our Technical Societies

My connection with the activities of technical societies has led me to the conclusion that, as they are organized, technical societies cannot do the things that we hope and wish to do, without losing something. And I believe that the country needs technical societies, high-class, far removed from all the sordid things that we may have to take up as a business organization of engineers.

I have no quarrel with any engineering organization, particularly any of the technical organizations of engineers. I believe they fill a want in the community. I believe they should continue; I believe they should be encouraged to fulfill their destiny. But my experience is that if they are organized as technical societies for the advancement of certain purposes they are not able to accomplish the things that should be accomplished for the engineer. And that has been growing upon the engineers of the country.

Concrete Material for Army Base Hauled by Motor Trucks

Special Equipment Utilized at South Brooklyn Supply Unit for Stevedoring and Haulage—Truck Performance and Cost of Delivery Analyzed

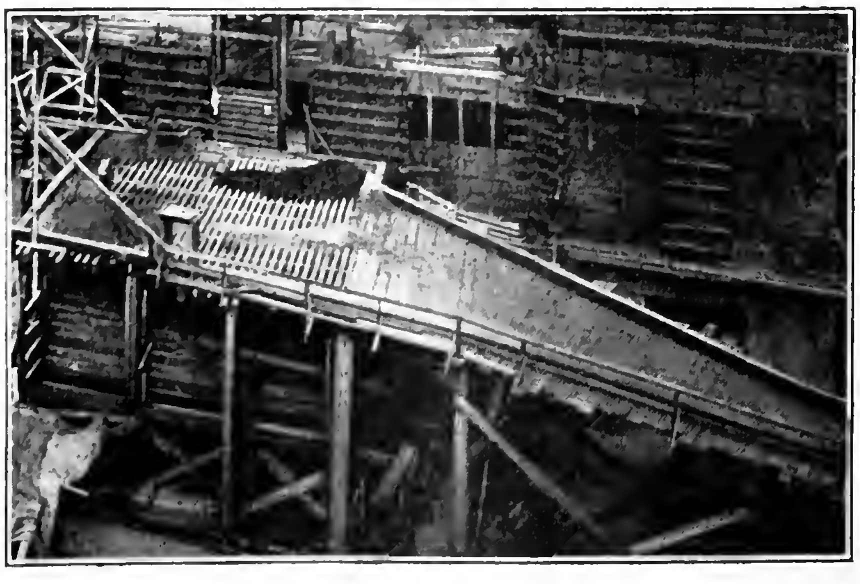
STEVEDORING and hauling of concrete material for the South Brooklyn Army supply base was accomplished by the use of specially designed equipment, working in conjunction with motor trucks. To deliver the aggregate for 250,000 cu.yd. of concrete, concentrated in a relatively small area and in a limited time, required a flexible organization and a systematic layout, so that one part of the work would not obstruct another. The layout selected consisted of long timber trestles to give elevation at the various dumps, connected with return driveways so that the trucks might work continuously around the circuit without interference. By this system the contractors were enabled to deliver aggregate at the work over an average haul of ½ mile for a haulage cost of 21c. per cubic yard, and at a total unloading and haulage cost of 50c. When indirect charges, such as repairs to docks, etc., are included, the total was about 59c. per cubic yard.

UNLOADING STATIONS ON WAREHOUSE B RUNWAY. CEMENT CHUTES IN FOREGROUND

The general dimensions of the warehouses, together with the excavation for them, were described in *Engineering News-Record* of Nov. 28, 1918, p. 993, and the design in the issue of Feb. 13, 1919, p. 317. The area covered by warehouse A was 196,000 sq.ft., that by warehouse B, 299,880, and that by the general office and power house 25,112 sq.ft. Each of the warehouses is nine stories high, including the basement and dock-floor levels, and the office building has four stories. The problem was to deliver the necessary material in this area with the required speed without causing congestion or piling it so as to obstruct traffic.

Two trestle runways about 25 ft. high and similar in design to those used for the construction of the offices of the War and Navy Departments in Washington, described in *Engineering News-Record* of July 4, 1918, p. 21, were constructed. They were built with heavy timber and strongly braced, the uprights and stringers being 12 x 12 in. A track on each side for the motor trucks, separated by wooden curbing, was formed by cross-planking over two closely placed 12 x 12-in. stringers. One trestle stretched along the east side of warehouse A, while the other passes through a central court of warehouse B, as shown in one of the views. A smaller one was used for office building work.

Four mixing stations were located under each trestle. Those on the warehouse A trestle had one 1¼-yd. mixer to each station. Those on the warehouse B trestle had two mixers, one for each half of the building. The trestles widened out from 10 to 30 ft. at the stations, as shown, and were floored with 4 x 10-in. planks on edge and spaced 4½ in. This formed a grate under which were the material bins for stone, sand, grits and cinders, as the case might be. A view of one of these grates is reproduced. Sufficient elevation, so that the bins containing aggregate could discharge by gravity into the charging cars below and in turn into the mixers, was obtained by means of the trestle. A cement chute was provided at the end of each station, down which the cement in bags was dumped by the trucks to the loading and storage floors. Two of these chutes may be seen in the foreground of one of the illustrations. The single stations had bin capacity for 320 cu.yd. of crushed stone, 160 cu.yd. of sand and 160 cu.yd. of grits. Storage space for 4000 bbl. of cement was provided on the charging floor. Materials were delivered by barges at docks which were about ½ mile from the northern end of the buildings. It was planned to have the loaded trucks proceed to the southern end of either trestle, up an incline which was built on a 6% grade, pass along the trestle, dump at the proper bin, and go down the other incline, returning by way of First Ave., which lies between the two warehouses. This was the general plan followed out, although at the start, on warehouse B, it was necessary for the trucks both to go and come by way of



UNLOADING GRATE AND BIN AT MIXING STATION

First Ave., on account of the unfinished condition of the excavation at the southern end of the building. This caused some inconvenience, making it necessary to flag trucks in and out. The average round-trip distance was about one mile.

In all motor-truck operations, the secret of efficiency is to "keep the wheels turning," and this principle was recognized in the layout of the plant. Mechanical unloading and loading of material, combined with the almost immediate disappearance of the material at the grates—thus leaving a clear road—made it possible for the trucks to make the round trip almost without stop.

CLAM DIGGER TRANSFERRING STONE FROM SCOW TO TRUCK-LOADING BIN

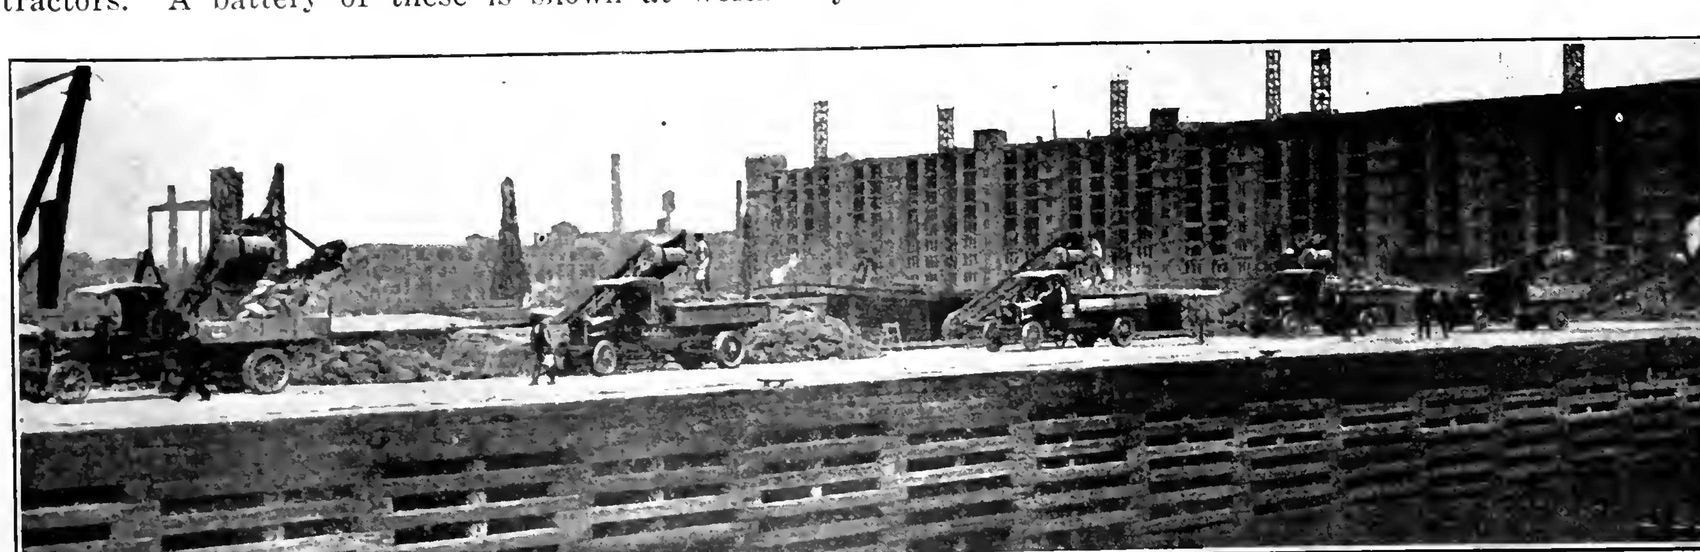
At the docks, the barges containing concrete aggregate were unloaded by two large skid diggers with clamshell buckets of about 5-cu.yd. capacity and two boom derricks with 1½-cu.yd. clams. The buckets dropped their loads into storage bins, as shown in an illustration. The bins were kept constantly filled, and the trucks were quickly loaded by gravity as they passed under the discharge. There were four of these bins, each having a capacity of 20 cu.yd., and the average length of time required to load a truck was about one minute.

Cement in bags was rapidly unloaded from the boats by conveyors designed and built by the general contractors. A battery of these is shown at work. By these conveyors the 110 bags required to make a load could be handled in 10 min. A full description of this apparatus, together with a special truck body which was used to some extent, appears on p. 396.

Although concreting began June 1 when the footings were started, the real rush commenced when the superstructure was begun July 3. From that date to Sept. 26, when the roof was completed, 183,173 cu.yd. of concrete were poured, or an average of 2130 cu.yd. per day. The maximum for any day's work was 4500 cu.yd. These large yardages of concrete required a proportionally greater yardage of loose material to be transported by the trucks. During the 64 days while the frames and floors of the buildings were going up, an average of 600 truck loads of material per 10-hour shift unloaded on the warehouse B trestle. Besides the hauling to buildings, large quantities of material were put in storage piles as insurance against shortage. While this required rehandling, it was considered worth while, to obviate any chance of delaying the completion of the contract. Piles were formed by starting a dump of the required width and gradually building up on a grade of 7 or 8 per cent., smoothing it out and planking the surface as the pile grew. The trucks would back up the grade and dump over the end of the plank. By this means, a pile containing from 9000 to 10,000 cu.yd. of crushed stone was kept stored,

TABLE 1—TRUCK PERFORMANCE IN HAULING TO BUILDING SOUTH BROOKLYN ARMY SUPPLY BASE FROM JULY 10 TO NOVEMBER 14, 1918

	Sand and Stone	Gravel	Grits	Cement
Average haul, round trip, miles	1	1	1	1
Auto truck hours	17,384	71	646	7,651
Auto truck loads—trips	59,899	152	2,014	12,615
Average trips per truck per hour	3.40	2.1	3.1	1.64
Average miles per hour	3.40	2.1	3.1	1.64
Cubic yards moved (boat measure)	246,131	621	8,519	1,308,225
Average load per truck, cubic yards or bags	4.1	4.2	4.1	194



BATTERY OF CONTINUOUS-BELT CONVEYORS TRANSFERRING CEMENT FROM BOATS TO MOTOR TRUCKS

TABLE II. COST OF STEVEDORING, HAULING AND RE-HANDLING MATERIALS FOR CONCRETE SOUTH BROOKLYN ARMY SUPPLY BASE, FROM START MAY 20 TO NOVEMBER 13, 1918.

Stevedoring and Hauling

			Direct Cost														Indirect Cost on 380,000 Cu.Yd.— Building, Repairing, Removing Plant and Towage Charges			
			Labor Loading, etc.		Hauling by Trucks		Loading Plant Rental		Supplies		Supervision Field and Office		Commission		Summary				Grand Total	
Items	Unit	Amount	Total	Unit	Total	Unit	Total	Unit	Total	Unit	Total	Unit	Total	Unit	Total	Unit	Total	Unit	Total	Unit
Aggregates	Cu.yd.	*337,481	$34,217 14	$0 10	$72,015 95	$0 214	$26,571 86	$0 079	$20,635 59	$0 061	$6,766.48	$0.020	$9,740 14	$0.029	$169,947 16	$0 504	$32,193 74	$0 085	$202,140.90	$0 589
Cement	Bbl.	393,692	3,861 86	0 01	28,772 50	0 074					900 52	0 002	1,943 35	0 005	35,478 23	0 090	4,329 95	0 011	39,808 18	0 101
									Rehandling											
Aggregates	Cu.yd.	* 26,749	10,228 13	0 382	10,437 50	0 39	4,056 50	0 15	1,051 00	0 039			1,325 89	0 049	27,099 02	1 01				
Cement.....	Bbl.	22,330	1,936 76	0 086	1,441 00	0 065							104 01	0 005	3,481 78	0 156				

*Quantities comprise stevedoring and hauling to building of following: Sand 122,949 cu.yd.; stone, 193,832 cu. yd., remainder being grits, cinders, paving blocks, coal and gravel. Rehandling covered 6,790 cu.yd. of sand, 19,355 cu.yd. of stone and 604 cu.yd. of grits

so that when it was needed the material could be reloaded by steam shovels working upon the last material stored, which in turn could be replaced.

The hauling was carried on by subcontract under the cantonment form for emergency work. The subcontractor was required to furnish all hauling equipment, labor and supervision. He was paid a rental for his plant and a commission not to exceed a fixed sum on the payroll and supplies.

Accurate costs were kept for the Government by the general contractor, who also kept close account of the performance of the trucks, in trips per hour, average load per truck, and mileage covered. A record of this performance is shown in Table I. Although the mileage covered per hour by the trucks appears low when contrasted with mileages covered on the highway, this may be easily explained by the impracticability of high speeds, the time for loading and unloading, and the delays due to various causes, such as train interference where the trucks passed over the switching tracks. The average load carried per truck was 4.1 cubic yards.

Table II gives the cost of hauling and rehandling materials. These costs do not include the construction of the timber trestles or the loading and unloading bins, which were charged to concrete. All other charges such as supplies, field and office supervision, and a commission of 6½ per cent., together with repairs on the plants, are included.

In Table II, which shows the unloading and hauling costs, the actual hauling cost per cubic yard is shown to be about 21c. Taking the average haul at ½ mile, the cost per ton-mile would be about 16c. The total cost of hauling and handling, including all charges, would be about 44½c. per ton. Hauling cement cost 7.4c. per barrel, while the total cost for handling and hauling, including all charges, was 10c. per barrel. Rehandling covered picking up material from the emergency supply dumps and carrying it to the work. The cost of this rehandling was considerably higher than was the cost of the original handling of the material.

The work is being done by the Construction Division of the Army. Brig. Gen. R. C. Marshall, Jr., is chief of the Construction Division, Lieut. Col. H. S. Crocker is constructing quartermaster, and Maj. George Perrine, Quartermaster Corps, National Army, assisted by Capt. J. W. McCathon, was directly in charge of the part of the work described. The general contractor is the Turner Construction Co., New York City, of which A. C. Tozzer is executive manager, and the subcontractor for the hauling is Rodgers & Haggerty, of New York City.

University Dean Urges Better Conditions for Railway Engineers

DR. C. R. RICHARDS, dean of the College of Engineering of the University of Illinois, has written the following letter to the Board on Railway Wages and Working Conditions of the United States Railroad Administration:

I have read with much interest the astonishing article entitled "Pay and Position of Engineers in Railway Service," by Charles Whiting Baker, which appeared in *Engineering News-Record* of Jan. 30, 1919, p. 228. While I have long realized that the railroads of this country offer few inducements which render the transportation service a particularly attractive field for engineers, I had not supposed that present conditions are as bad as Mr. Baker's article indicates.

Believing that the transportation interests of the country are fundamental to its growth and industrial prosperity, the University of Illinois has done much to promote the scientific study of problems relating to both the engineering and the administrative work of the railroads. Thus, the College of Engineering offers specialized curriculums in railway civil engineering, railway electrical engineering and railway mechanical engineering, and the College of Commerce and Business Administration offers curriculums in railway administration and railway transportation. To coördinate the administrative and engineering work, we have a School of Railway Engineering and Administration.

In spite of facilities for instruction which are not surpassed anywhere, very few students are attracted into these railway engineering and transportation courses. However fascinating this work may be to the average young man, it is generally recognized that the railroads of the country apparently have so little appreciation of technical and scientific training that they are unwilling to pay to trained experts salaries which are comparable with those offered by industrial corporations.

When a young man asks my advice regarding the opportunities for a successful career in this field, I feel obliged to tell him what the real conditions are. You cannot expect a young man to spend four years in college, with a more or less indefinite apprenticeship thereafter, to prepare himself for a position in the engineering department of a railroad at a salary below that of clerks and mechanics and very much below the salary paid to trainmen. It has been my hope that one of the effects of Government control would be to improve the status of trained experts. In my opinion it is vastly important that the railroads of the country apply the soundest engineering and economic principles in the conduct of their business, for I am convinced that it is only by such means that they will be able to maintain an efficiency which will be satisfactory to their stockholders and to the public.

Material Prices Halt Chicago Building Operations

Costs $1,873,239 Today to Erect a Building Costing $1,000,000 in 1915—Wage Increase Only Partial Cause

By O. M. Fox

BUILDING construction is slow in recovering from the depression caused by the war. When the fighting stopped last November an immediate increase in building was prophesied. Work costing millions of dollars was announced ready for contract as soon as war restrictions were removed. Today, more than three months after release from the stress of hostilities, there is no building under way, nor is any construction announced for the immediate future, except some few improvements which are absolutely indispensable.

Analysis of the construction cost of a hypothetical building at present prices, compared with a similar enterprise carried out in 1915, may perhaps set us on the track of the correct answer.

The accompanying tabulation shows actual costs on a building which was erected in Chicago in 1915, compared with the costs of the component parts thereof as of today's market prices and wages:

	Actual 1915 Costs	Ratio	Estimated 1919 Costs
Masonry..........	$175,400	1.52	$266,608
Steel, material....	100,700	3.15	317,205
Steel, erection...	20,100	1.29	25,929
Foundations.....	81,100	1.54	124,894
Elevators..............	74,000	2.00	148,000
Carpentry..............	73,800	1.86	137,268
Ornamental iron work	62,600	2 20	137,720
Heating and ventilating.	62,100	1.92	119,232
Fireproofing	47,000	1.70	79,900
Engines and generators	41,000	2.00	82,000
Plumbing, drainage	30,800	1.54	47,432
Electric wiring.	29,500	2.00	59,000
Terra cotta....	26,500	1.70	45,050
Various minor items, e.g., glazing, hardware, roofing, painting, lighting, etc....	129,200	1.50	193,800
Architects' and engineers' fees..........	46,200	...	89,201
	$1,000,000	1.87	$1,873,239

These figures of ratio of 1919 costs and the resulting estimates were arrived at in the following manner:

Masonry—Each thousand dollars of expenditure in this division of the job is split as follows:

Item	Cost per Unit, 1915	Amount	Cost per Unit, 1919	Amount	Per Cent. Advance
Brick........	$7.50	$535.70	$12.00 M.	$918.73	71 5
Lime.............	1.50 bbl.	107.20	1.80 bbl.	128.64	20.0
Sand.............	1.35 yd.	35.70	2.10 yd.	45.41	27.2
Skilled labor......	.75 hr.	160.70	.87½ hr.	193.49	16.7
Common labor....	.40 hr.	160.70	.57½ hr.	230.93	43.7
		$1000.00		$1517 20	51 7

Foundations—Concrete caissons were placed under the structure. The division of expense on this class of work per $1000 is as follows:

Item	Cost per Unit, 1915	Amount	Cost per Unit, 1919	Amount	Per Cent. Advance
Cement.........	$1.02 bbl.	$353.00	$2.05 bbl.	$709 53	101 0
Sand and gravel...	1.35 yd.	401.00	2.10 yd.	510 07	27 2
Skilled labor......	.65 hr.	115.00	.75 hr.	132 71	15 4
Common labor....	.40 hr.	131.00	.57½ hr.	188 25	43 7
		$1000.00		$1540.56	54 1

Steel—Steel was furnished on the job in question at $36.50 a ton, f.o.b. Chicago, while current bids on a proposed job range from $110 to $120, or an average advance of 317 per cent. Structural-steel setters' wages in 1915 were 68c. and are now 87½c., an advance of 28.7 per cent. As exact figures are available for a separation of this item into material and erection, it is so shown.

Elevators—In line with all other machinery, elevators are costing approximately twice what they did four years ago, as are also engines and generators.

Carpentry—The price of yellow pine in 1915 was $18, against a quotation of $45 today. The local carpenters' scale was 65c., contrasted with 80c. at present. Allowing half the cost under this head to apply to material and half to labor, we find the cost to have advanced 86.5 per cent.

Ornamental Iron Work—This consisted mainly of iron and labor, in proportion of three to one. With a 150% advance in iron, from $14 to $34.75 per ton, and a 30% advance in iron setters' wages, from 67½c. to 87½c. an hour, the increased cost of this class of work aggregates 120 per cent.

Heating and Ventilating—Iron has advanced from $14 to $34.50 a ton, or 147%, and labor from 75c. to 81¼c. or 9%. Allowing this cost to be split 60% material and 40% labor, we find the advance under this head to be 92 per cent.

Fireproofing—Tile shows a cost increase of 100% from 3½c. to 7c. per foot on a given size, and labor an increase of 9%, from 75c. to 81¼c. About two-thirds of the total cost of fireproofing being material, we find the advance to date to be 69.6 per cent.

Plumbing and Drainage—Metal markets have advanced thus: Lead from $3.80 to $6, brass from $15 to $31, copper from $13 to $23 and iron from $14 to $34.50. The plumbers' scale was 75c. and is now 81¼c. Figuring the average metal advance to have been 100% and the labor 8⅓%, and figuring material at half and labor half of the whole, the resulting increase in cost figures 54.2 per cent.

Electric Wiring—Without troubling to go into detailed figures, it is safe to say that the various lines of conduit and flexible duct have advanced to 2½ times their cost of four years ago. Copper wire has doubled, as have also practically all other elements of this work except labor, on which the scale has advanced 16%. It is, therefore, reasonable to assume that the cost under this head will average double that of the other job.

Terra Cotta—Although the market in this commodity is somewhat deranged at present, no actual quotations being available, it is probably safe to assume that the increase in its cost is very similar to that of fireproofing and it has been so figured.

Minor Items—Too much space would be consumed in analyzing all of the lesser items of construction cost in this short exposition. It is sufficient to say that they have been carefully studied, and that the average increase of 50% as figured in the table is conservative in the extreme.

Architects' and engineers' fees, of course, increase in exact proportion to the average increase in the various other items.

The hypothetic cost figured above has been compared with the actual costs on several jobs of varying grades which have been recently put under way, and are found to be remarkably close to the actual, the slight difference being, in each case, in the direction of greater advance.

We, therefore, arrive at the conclusion that a building

erected today to compete with the $1,000,000 "before-the-war" structure would cost $1,873,239, or an advance of 87.3%. As the older structure has to bring an average rental of $2 per square foot in order to return from 4½ to 6% on the investment, it is apparent that a rental of $3.75 will be necessary in its new competitor, and as the obtaining of such a rental in Chicago is obviously impossible, therein seems to be the reason why building construction is not being undertaken.

The particular subject of this study happens to be an office building, but what is true of a modern office building is equally true in the case of a factory, a hotel, an apartment or a home. The present cost of buildings in all lines is such as to be practically prohibitive.

New York Barge Canal's First Operating Season

One Federal and Two State Officials Report Independently on Canal Operations Under Federal Control, and Give Reasons Why It Carried Less Freight Last Season Than Ever Before

On April 22, 1918, the United States Railroad Administration created the New York Barge Canal Section and authorized the construction and acquisition of equipment for use on the state system of canals which, it was expected, would be opened complete for the first time some time in May. The Federal Government did not take over the canals as a whole, as was commonly believed at the time, but it did assume control of rates, and purchased and leased floating equipment which it proposed to operate. The season opened May 10 and closed Dec. 12, the longest since 1907. In spite of this long season, the recognized necessity for freight carriage and the fact that the canal enlargement was complete, the business done was less than in 1917, which in turn was the smallest in the canal history.

The history of the year is now available in three separate reports, one by W. G. McAdoo, director general of the Railroad Administration, one by Frank M. Williams, state engineer of New York, and the third by W. W. Wotherspoon, superintendent of public works of New York. Enough of the three reports is given here to explain the conditions of the canal operation and to expose certain divergencies of opinion between the state and Federal authorities.

Comparative statistics of freight carriage on the completed Barge Canal system in 1918 and the combined Barge Canal and Erie Canal in 1917 are given in one of the accompanying tables, and total tonnage figures for the past 10 years in the other.

Report of the State Engineer

The State Engineer of New York is responsible for the construction of the canal. When sections are complete he turns them over for operation to the Superintendent of Public Works. As an introduction to the story of the operation, therefore, there is given here a part of State Engineer Williams' report for 1918:

In my report of a year ago I promised that the new canal would be opened to navigation throughout its entire length on May 15, 1918, and that it at that time would have been constructed to its full depth of 12 ft. That promise was fulfilled, even in spite of the fact that more numerous and greater difficulties arose to defeat the accomplishment than were anticipated when the promise was made.

Under the authority conferred upon the President of the United States to take over and operate canals and their floating equipment, and in accordance with the Federal plan to assume control of the transportation media of the country, the United States Railroad Administration assumed control of the canals in a somewhat limited manner. According to our state constitution the canals must remain forever the property of the state. The state has always maintained and operated them and during Government control it has continued to do this, the same as heretofore. Unlike its administration of the railroads, the Federal Government was not called upon to assume certain financial obligations in connection with the canal. What it did was to take over control, either directly or indirectly, of the floating equipment on the canal. It obtained control of a large proportion of the boats which had been in use on the canal during recent years, although the whole number of such available craft is not large, and it built a few new boats, which were just beginning to be delivered when the navigation season ended.

However, the Government became more than a mere transportation company; it stood ready to control all shipping on the canal, assuming the right under authority of Congress to commandeer any and all boats doing business on the waterway and even to direct the activities of those it did not commandeer. In fact, for some time the impression was general among the independent boatmen that the Government would not permit them to operate on the canal. Of course, the Government had no authority to grant or withhold permission to float a boat on the canal. Such authority rested solely in the Superintendent of Public Works of the state and could only be exercised by him. However, the Government could fix canal rates and it proceeded to do so. Much criticism has been aroused by this fixing of an arbitrary rate for interstate traffic approximately 20% less than the railroad rate. It is claimed that this is not based on operating expense and that the differential in favor of the canal would be much greater if the rates could adjust themselves as they had heretofore. The fleet of boats operated by the Government was entirely inadequate, both in number and dimensions, to test the canal's capacity. The new boats which were ordered built were not delivered in time.

The canal was handicapped during the season by much misinformation regarding its condition and possibilities for use, which was spread broadcast, perhaps without malicious intent, but generally without any basis in fact. That the Barge Canal should be completed to a point which permitted its full utilization seemed beyond the belief of many who had noted the long years during which it had been under construction. Entirely new navigation conditions aroused the timidity of the man accustomed to navigation on a shallow, restricted channel. His fears or ignorance often gave rise to false stories of conditions. The mere fact, however, that there have been brought through the entire line of the canal boats having a width of not less than 30 ft. and drawing 9½ ft. of water, as shown by the records of the office of the Superintendent of Public Works, should indicate that the canal is, as claimed, in a condition to accommodate the size of floating equipment for which it was designed and constructed.

Superintendent of Public Works Wotherspoon's comments on operation are partly as follows:

One who studies the record made during the first season of operation of the improved waterways and analyzes the freight movement can take no discouragement from the results attained, in spite of the fact that the total tonnage

fell below the 1917 business by 137,955 tons. He cannot fail to be impressed with the many indications of the rehabilitation of the canals as a commercial factor.

The figures covering the past 10 years of canal navigation show a steady annual decrease, amounting yearly to more than 15 per cent. The opening of the new waterways, while not reversing such process, has arrested the decrease so that the total for 1918 is only about 9% under that of the previous year. Were it not that extraordinary conditions existed, due to the war, it is believed the 1917 tonnage would have been exceeded. This statement is made in view of the great falling off in items of freight whose production was mainly dependent on labor which could not be secured owing to the military draft.

Another feature that stands out prominently is the comparatively small west-bound canal shipments. The decrease must primarily be attributed to the disturbed commercial conditions. A large portion of the industrial activity in the canal territory was in connection with what has been termed "war work." The industries working on war contracts for the most part drew their raw materials from Western producing centers, principally the iron and steel districts. Practically all of the raw materials, therefore, which were consumed in canal territory moved in an easterly direction to the mills, and when manufactured, continued east to seaboard. In normal times the markets of industries in the canal zone extend to the middle and northwest and the flow of west-bound traffic is heavy. During the past year the market or consuming territory was overseas or the military camps adjacent to the Atlantic seaboard. The normal west-bound traffic was naturally affected. Then, too, the discontinuance of imports due to wartime conditions had its effect on the canal business.

In a study of the record of the total business done in the past five seasons the through freight has averaged 27.6% of the total, and the way freight 72.4% annually. For the four years previous to 1918 the total was divided on averages of 25% of through freight and 75% of way freight. In 1918, however, the through freight represented nearly 40% of the total, and the way freight about 60%, thus showing that the long-haul traffic, which is the most desirable from the standpoint of revenue to the carrier, has greatly increased. This again evidences the restoration to the canal of a class of commerce which is much to be desired.

The falling off in shipments over the Oswego, Cayuga and Seneca, and Black River Canals was due to the fact that no service was offered to shippers in those territories, the Federal authorities confining their operations entirely to the main or Erie Canal. In previous years the Oswego, Cayuga and Seneca, and Black River Canals contributed approximately 10% of the total tonnage. During the past season the percentage of contribution of all three lateral canals amounted to only 3.9% of the grand total. [4.9%, according to figures.—EDITOR.]

On Apr. 18 formal announcement was made by the Director General of Railroads of his intentions to secure boating equipment and establish an operating organization to utilize the state canals. A complete organization was effected, with headquarters in New York City, and representatives at various points along the line of the waterway. Approximately 200 of the old-type canal boats were acquired by the Federal authorities by charter. A few tugboats were purchased and a number of others leased for the season. It was announced that operations would be extended to Erie Canal freight only, for the reason, I assume, that the transportation business on the Champlain Canal was well organized, and because the traffic movement in which the Federal Government had the greatest interest moved to the seaboard by way of the Erie Canal.

At the opening of the season, it became apparent that the plans adopted included only the transportation of bulk freight, particularly grain and grain products from the West. While recognizing the supreme importance of this class of traffic and its relation to the nation's military program, I believed that such utilization of the New York canals by the national Government to the exclusion of traffic produced and consumed by shippers located along the waterway from Buffalo to the Hudson River was unfair to New York State's interests. I have always taken the position that since the canals have been built solely by this state, its citizens were entitled to the full benefit of them and to that end, in addition to the movement of Government materials and supplies, some of the boats under Federal charter should be placed at the service of industrial establishments having freight for shipment. The soundness of these views was recognized by the Federal manager, and early in July a fast freight carload and less-than-carload merchandise service was inaugurated, serving some of the larger cities along the route.

TABLE SHOWING TONNAGE CARRIED ON NEW YORK CANALS IN 1917 AND 1918

Year 1917	Branch	East-bound	West-bound	Total	Total Is Made up of Through	Way
185 days open	Erie	518,608	156,475	675,083	76,981	598,102
	Champlain	332,561	183,193	515.754	158,931	356,823
	Others	62,453	43,935	106,388	41,554	64,834
	Total	913,622	383,603	1,297,225	377,466	919,759
1918						
216 days open	Erie	577,155	90,219	667,374	148,353	519,021
	Champlain	296,833	137,951	434,784	293,726	141,058
	Others	15,791	41,321	57,112	4,676	52,436
	Total	889,779	269,591	1,159,270	446,755	712,515

During the first few weeks of the season some opposition developed to what seemed to be a monopoly by the Railroad Administration of all Erie Canal traffic. A conference with shipping interests was called in the latter part of June in the City of Albany, at which this question and the rate level were discussed. At that time, the Federal manager formally announced that there was nothing in the Director General's policy, as it would be carried out, which would prevent entrance of freight-carrying companies into the canal transportation field. The season being well advanced, however, no new companies made their appearance, and the Federal Government continued to be the only carrier operating on the Erie Canal.

The freight carried amounted in all to approximately 210,000 tons, or about 18% of the total of all the canals, and approximately 30% of the Erie Canal tonnage. It was made up of the following items: Wheat, salt, general merchandise, flaxseed, flour, pig iron, copper, coffee, barley, oil meal, oats and other commodities.

Due credit should be given to the canal operations of the Federal officials for some excellent results obtained, in spite of the fact that their work progressed under many handicaps, due to the inadequacy of the available boating equipment and the lack of suitable motive power. To this latter cause may be attributed the excessive time consumed in making passage through the waterway from Buffalo to the Hudson River. With proper equipment five or six days should be ample for the trip. Of 209 grain cargoes loaded at Buffalo, the fastest time recorded for passage to the Hudson River by the Federal boats was 10 days, and the average time consumed was something over 18 days. There is a record of barges having been in transit much in excess of that number of days. It is true, perhaps, that no urgent need existed for a speedier delivery, but in the interest of the rehabilitation of canal commerce it is to be regretted that effort was not made to establish records for trips which would furnish a guide for the carriers of the future.

The excessive time required for the passage of some of the boats can be attributed also to the disinclination, and in many cases the positive refusal, of boatmen to navigate the canal by night. No good reason existed for this other than the difficulty of obtaining additional crews. An elaborate system of lights was maintained on each side of the channel where necessary, and the navigable conditions were equal to those existing on any natural waterway.

REPORT OF THE RAILROAD ADMINISTRATION

The difficulties surrounding operation make up the larger part of Mr. McAdoo's report, the greater part of which is given below:

Contracts were early let for the construction of 51 steel barges, 150 ft. long, 21-ft. beam and 12-ft. molded depth, for service on the Barge Canal, at a cost of $1,697,708, and

TABLE SHOWING TONNAGE CARRIED ON NEW YORK CANALS IN PAST 10 YEARS

Year	Days Open	Total Tonnage
1909	185	3,116,536
1910	185	3,073,412
1911	185	3,097,068
1912	185	2,606,116
1913	172	2,602,035
1914	201	2,080,850
1915	200	1,858,114
1916	200	1,625,050
1917	185	1,297,225
1918	216	1,159,270

for 21 concrete barges of similar dimensions for $458,996. [None of these barges was delivered for the 1918 season.—EDITOR.]

In addition to these contracts, five tugs were purchased, for a total of $56,500, and three wooden barges were purchased on the stocks for $52,650.

During May the general manager had under lease 13 steamers and 118 barges; during June, 14 steamers and 140 barges; during July, 14 steamers and 168 barges; during August, 14 steamers and 175 barges; during September, 14 steamers and 180 barges; during October, 12 steamers and 188 barges; during November, 12 steamers and 180 barges. The average time these vessels were under lease was 27 days per month. All this equipment was of the type that had been in use on the New York Barge Canal for many years, the vessels being designed to draw not more than 8 ft. of water. The 250-ton barges were chartered at $11 per day, including crews; the larger barges at $15 per day, including crews; the steamer and push boat at $50 per day, including crew but not including fuel and oil.

It will be noted that the fleet was gradually increased from the opening of navigation, with the expectation that in July and August a heavy east-bound canal business in grain would develop, as was anticipated by the United States Food Administration Grain Corporation. As a matter of fact this grain was shipped by the owners by rail.

The additional charters were not always completed the first day of each month and the record shows that from May 10 to Dec. 1 an average of 169 barges were in service. The period covers 203 days, so the operation covered 34,307 boat days.

Vessels of the fleet were idle on account of no cargoes as follows:

	Days
May	1,130
June	905
July	448
August	531
September	118
October	192
November	43
Total	3,367

The total number of serviceable boats on the New York Barge Canal is estimated at 760. The fleet not under Federal operation was engaged very largely in short-haul work, while the administration fleet was engaged exclusively in through service. The independently operated boat made its own transportation rate.

At the beginning of operation by the Railroad Administration it was found by actual experience that the minimum depth of the canal did not permit loading vessels to a draft in excess of 7 ft., and up to the close of navigation not more than 8½ ft. was available. The terminals at Buffalo and New York were not completed by the state and are not yet completed, so that the Railroad Administration was required to create temporary terminals. Rochester is as yet accessible only through the old canal, and Syracuse was not accessible by the new canal until September.

The inadequate equipment, which on account of war conditions was all that was obtainable for the past season, and the incomplete state of the canals and terminals, of course made the operating conditions very different from what they will be with new equipment adapted to the new canal and with the canal facilities completed, so that the operating results for the present year are not a measure of what may reasonably be expected in the future.

The movement of freight on the New York Barge Canal by all transportation agencies this season will approximate 1,200,000 tons, about the same volume as last year. Commodities such as building materials, pulp wood, road metals, coal to Canada, etc., always constitute a considerable percentage of the total traffic. The movement in these items decreased 250,000 tons. This decrease may be attributed directly to the war. Owing to the shortage in Northwestern grain crop of 1917, it was impossible during 1918 to obtain any cereal for shipment from Buffalo via the canal until late in September. Grain must always be a very large tonnage factor on the barge canal, and the crop shortage of 1917 was a serious handicap to the usual activities of 1918. Imports were almost entirely cut off at the port of New York and the west-bound movement of freight on the New York Barge Canal has been negligible.

An effort was made to stimulate a movement of coals. Manufacturing enterprises along the waterways were solicited to arrange for the receipt of water-borne coal at their plants. Many receivers said they preferred delivery by rail. There is practically no coal unloading equipment at canal bank, and receivers would not purchase the necessary machinery. It was, therefore, impracticable to construct loading tipples without some assurance they would be of value.

Because of the lack of suitable canal terminals in the port of New York, the barges were compelled to await the convenience of ocean vessels, and as the supply of ocean ships was intermittent, great delays were encountered in discharging cargoes. The lay time at terminals amounted to 1445 days.

The average running time between Buffalo and New York was 18 days towed by tugs, and 13 days for vessels towed by steamers. The average loading or unloading time was five days. The number of loaded boats dispatched during the season follows:

	Westbound	Eastbound	Total
May	14	17	31
June	15	93	108
July	62	78	140
August	50	101	151
September	40	113	153
October	33	139	172
November	12	89	101
Season total	226	630	856

A packet-freight service between Buffalo and Albany was established. Agencies were established in 11 cities. In view of the fact that only small unserviceable packet-freight ships were obtainable, satisfactory financial results were not expected or realized. The service was maintained until Nov. 1. Most of the freight offered was extremely bulky.

When navigation opened freight rates were established all-rail basis, both for local New York State traffic and for interstate traffic. The public was adverse to using the canal at all-rail rates. At the time all-rail rates were in effect on interstate traffic on the canal, the Canada Atlantic Line was maintaining a differential under standard all-rail rates of 10.8.6.4.4.3 on the various classes and commodities. All-rail rates continued until June 25, 1918, when on local New York State traffic a differential of 20% under all-rail rates was authorized. On interstate traffic for points beyond Buffalo to which we had through rates a differential under the all-rail rates of 10.8.6.4.4.3 was promulgated.

There has been a demand for a greater differential between the canal and the rail rates. In view of the actual cost of conducting the transportation on the canal during the past season, a greater differential appeared to be unjustified. The question whether there should be any readjustment of the differential is receiving consideration.

During the season we have handled a total of 194,201 tons at total gross freight revenue of $522,883.50. These tonnage and revenue figures will be slightly changed when our season is finally completed. This tonnage represents a much larger proportion of the total traffic carried on the canal than would be indicated by a comparison with the total tons carried by all transportation agencies, because a large proportion of the Railroad Administration business is through business, whereas other agencies are more largely engaged in local traffic, so that the average distance is much greater on the Railroad Administration traffic.

War's Influence on the Garbage Pail

F. C. Bamman
Consulting Engineer, Washington, D. C.; Formerly Chief of the Garbage Utilization Division, United States Food Administration

The amount of garbage collected during 1918 averaged about 10% less than that collected in 1917. Collections during the summer months of 1918 also averaged about 10% less than for 1917; compared with 1916, the reduction was 22½ per cent.

The 1918 grease content of garbage, its richness, averaged 18% less than in 1917; compared with 1916, the richness of 1918 garbage showed a reduction of about 25 per cent.

The total volume of garbage grease recovered showed a reduction of 28% from 1917 recoveries. As 1917 recoveries exceeded those of 1916 by 13%, the 1918 reduction was only 19% less than in 1916.

Changes to feeding during the year totalled 40, some of them being cities of over 10,000 population; changes to reduction totalled 3.

The amount of garbage still wasted is sufficient to produce more than 30,000,000 lb. of garbage grease, 60,000 tons of fertilizer tankage and 40,000,000 lb. of pork.

FROM a popular point of view, garbage might well be considered as a war-time discovery; something which had no existence in pre-war times. While considerable technical literature on the subject is available, and engineering journals have devoted considerable space to the garbage problem, the general public seemingly remained in ignorance that such a thing as garbage existed; probably, more correctly speaking, the general public was exceedingly indifferent to the subject; the word was in ill repute and the "garbage business" considered as all but illicit.

High prices, the shortage of food and the patriotic response to the need of war-time conservation all combined to focus attention on the garbage pail, and brought about a remarkable change in the attitude with which garbage was regarded. Archaic "sanitary regulations" prohibiting anything but the burning of this waste were set aside almost over night; others were changed to eliminate certain portions which had prevented the utilization of the waste to best advantage; the housewife recognized garbage as a necessary evil, and cut down in every way possible the material finding its way into the garbage pail, while cities having low per capita productions congratulated themselves. On the other hand, many fantastical schemes for recovering the values in garbage were set forward, and a number of failures are to be noted because of the lack of observance of even the fundamental principles underlying its utilization.

The housewife seemingly decided to solve the garbage problem once for all by eliminating garbage. She unquestionably cut down materially not only the volume of her kitchen and table refuse, but even further reduced its meat and fat content.

While elimination of garbage is undoubtedly the ideal solution of the problem this waste represents, even the best efforts of the housewife failed, and they will continue to fail until such time as the nature of our ordinary foodstuffs undergoes considerable change. Great reductions have been claimed by some cities; in fact, claims of entire elimination for considerable communities are not unknown, and any number of cities where mixed or combined collection prevails have reported their respective communities producing so little garbage as to make segregation useless. In cities having separate collection of garbage, the authorities, and even the contractors for disposal, claim as high as 50% decrease in volume. Investigation in such cases almost invariably discloses a large portion of the garbage finding some other outlet.

The plea for conservation of paper, rags, etc., has had a decided effect in cities maintaining a separate collection of such wastes. It is reasonable to suppose that this same decrease has occurred probably in all cities, and that any great reduction with single collection of all wastes is made up partly by lessened quantities of household wastes other than garbage. The high prices of byproducts have also encouraged private collectors to extend their operations, and there are very few cities which do not report that at least a part of their garbage is utilized.

The campaign for food conservation did not gain full force until late in the summer of 1917, and the first year of garbage collections under war conditions may be said to have ended with April, 1918. The year 1916, while possibly not normal because of high prices, did not have the patriotic stimulus condemning wastefulness, nor was an organized effort made to increase exports to the allies. Table I, based on data compiled by the Statistical Division of the Food Administration, shows in part that for a number of cities, and a combined population of over 26,000,000, the reduction for the year which ended April, 1918, over that for the previous year, averages 10 per cent.; the per capita figure is 17 lb. less than for the previous year. For June to October, inclusive, the summer season when garbage production is at a maximum, 1917 collections show a reduction of about 9% under 1916, 1918 shows about 10% less collected than during 1917, while a comparison of the summer season of 1918 with that of 1916 shows a decline of 22½% in collections.

The data given in Table I include reports from a number of cities known to be using a mixed collection system. It is not known how the garbage content of

NOTES—Due to failure to receive reports, evident errors, etc., the total population reporting has changed each month. The per capita figures given for 1916 (Col. No. 13) and in the first of the two columns headed 1917 (Col. No. 14) have been determined by using the population reporting during 1917 (Col. No. 3); those for 1918 (Col. No. 16) and in the last of the two columns headed 1917 (Col. No. 15) are based on the population reporting during 1918 (Col. No. 5).

For purposes of comparison with annual per capita productions, the figures given in columns Nos. 13, 14, 15 and 16 are the monthly per capita figures (production in pounds divided by population) multiplied by 12.

The relative amounts given in columns Nos. 10 and 11 have been determined by the equation—production in last year named is to production in first year named as 100 is to x. The relative amounts given in column No. 12 have been determined by multiplying the 1916 production by the 1918 population and the 1918 production by the 1916 population and applying the above equation.

such mixed collections was obtained, and it is doubtful, from the per capita figures reported, whether any attempt has been made even to estimate the garbage content of the total material collected. The data collected by the Statistical Division again emphasize the lack of uniformity in waste-production records.

The detailed figures on which Table I depend show 81 cities with reduced collections. The four showing the greatest percentage of reduction either collect combined wastes, or the validity of their records is questionable. Buffalo, N. Y., stands fifth on the list with a reduction of 29 per cent.; Chicago is 14th with a 25% reduction; Boston and Detroit show a 12% reduction. The remainder of the larger cities show reductions of less than 10 per cent. Of the cities showing a reduction of over 25 per cent., six collect garbage and their household wastes combined, or have poorly organized collection systems. The remaining seven cities are believed to have reasonably accurate figures, the reductions being 40, 33, 29 (4 cities) and 26 per cent.

Table II shows detail figures, covering the same periods as Table I, for certain larger cities separately collecting this garbage. It is rather significant that the relative figure of this table is 93.1, denoting a reduction of less than 7%, whereas Table I shows almost 10 per cent. This seems to bear out the idea that large reductions reported are due to decrease in wastes other than garbage.

Buffalo, which had a high percentage reduction, is omitted. The per capita figures for this city show 93 lb. for 1916-1917 and but 66 lb. for 1917-1918. It is felt that this per capita production is so low as to indicate that a large part of the garbage found some other outlet and was not reported with the city figures. Chicago and St. Louis have also been omitted. The data for St. Louis show a reduction of about 13%, the per capita figures being 98 and 85 lb., respectively. Private collectors operate in St. Louis to no inconsiderable extent; their operations increased materially with the increase in the price of pork, and have so reduced the amount of garbage handled at the reduction plant as to compel the operating company to advise the city of its intention to close the plant.

The omitted data on Chicago are very illustrative of the danger of reliance on per capita figures. The city reports show a tonnage of 124,496 in 1916-1917 and 93,235 in 1917-18. On a per capita basis this gives 100 lb. and 75 lb., respectively. While Chicago has always been credited with having a low per capita production, the figures used in such cases have invariably been based on the amount of material being collected by the city. As a matter of fact, these figures represent only such material as finds its way to the municipal garbage

TABLE II. GARBAGE COLLECTED DURING YEAR ENDING APRIL, 1918, COMPARED WITH COLLECTIONS FOR YEAR ENDING APRIL, 1917

plant, and practically no hotel, restaurant or lunchroom garbage is included. Reports from private collectors in Chicago show at least an additional 40,000 tons privately reduced during the year which ended last April. This alone is sufficient to increase the per capita figure from 75 to more than 100 lb. Even these figures do not take into account the amount of garbage hauled from the city and used for hog feeding, neither is included such garbage as is burned, an investigation of garbage collections in Chicago indicating that last July a population of over 300,000 was disposing in privately owned incinerators of its kitchen and table refuse.

Table III gives in detail collections during 1916, 1917 and 1918 for New York, Chicago, Detroit, Columbus and 16 of our larger cities having separate collection of garbage. The severe weather conditions of last winter show their influence on the amount of garbage collected and are the cause of some fluctuation in per capita figures. The surprisingly low figure for Chicago in May, 1917, is due to labor trouble at the plant, it having been necessary to dump a large part of the material collected during that month.

For convenience in comparing with annual figures, the monthly per capita figures in each of the tables have been given in terms of pounds per annum. The actual per month production can be obtained by dividing the given figure by 12.

It has long been recognized that the true measure of a conservation effort lies in the reduction of the grease content of the garbage rather than in its volume. Many of our vegetable foods contain a considerable percentage of material not at all suitable for human consumption when purchased. This must necessarily find its way into the garbage pail, and a season of cheap vegetables may increase garbage production even when conservation has been most carefully observed.

The data accumulated for the fertilizer administration include a very complete record of garbage grease recovery during several years past. These data, however, were obtained under Congressional authority, and detailed information cannot be made available. Such restrictions, however, do not apply to totals of production, etc. Table IV has been made up from this record and gives data for five municipal plants and for all plants handling garbage, whether municipal or privately owned. These comprise about 70 plants, in varying degrees of efficiency.

a November and December estimated. b December estimated c Total for seven months d Total for eleven months.

It will be noted from Table IV (see next page) that in both instances the amount of garbage treated during 1917 is greater than that handled during either 1916 or 1918. The amount of grease recovered decreased each year in the case of the municipal plants, while the total recovered by all plants was greatest in 1917. In spite of this increase in grease recovery, the yield per ton of garbage was less in 1917 than in 1916, the richness of the garbage decreasing each year. The average recovery per

TABLE IV. GARBAGE REDUCED, GREASE RECOVERED AND TANKAGE MADE—1916, 1917 AND 1918

	Total of Five Municipal Reduction Plants			Total of All Municipal and Privately Owned Reduction Plants		
	1916	1917	1918	1916	1917	1918

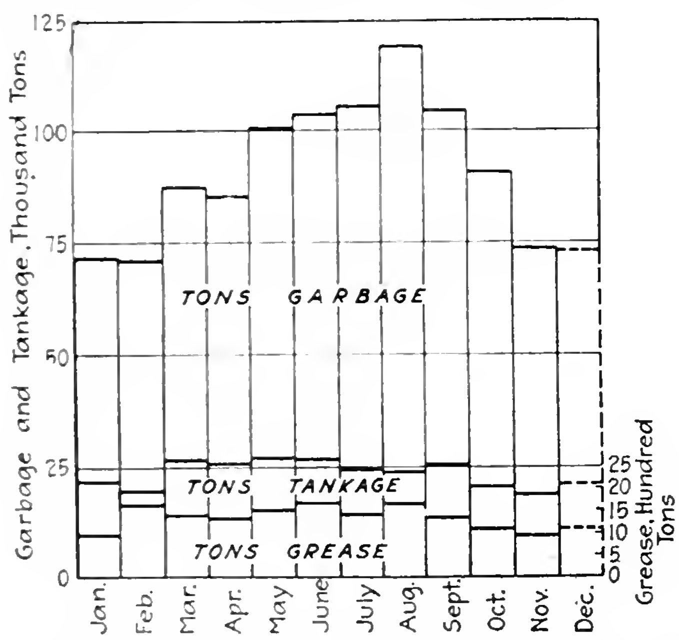
Pounds grease recovered per ton garbage	54	44	41	67	61	50
Pounds tankage recovered per ton garbage	464	334	284	253	262	286
Relative figures, 10 as base	1917 to 1916	1918 to 1917	1918 to 1916	1917 to 1916	1918 to 1917	1918 to 1916
Grease recovered	90	86	76	113	72	81
Grease per ton	81	93	76	91	82	75
Tankage recovered	79	78	62	129	95	123
Tankage per ton garbage	72	85	61	103	109	113

ton of garbage for all plants exceeds the recovery of the municipal plants alone. This is doubtless occasioned by the fact that the total figures include returns from plants handling only the better grades of garbage, plants in which the grease content runs as high as 8 and 10 per cent.

Relatively, the grease recovery per ton, or the richness of the garbage, shows a somewhat small drop. Comparing 1917 with 1916 this decrease equals 19% for the



GARBAGE REDUCED AND PRODUCTS RECOVERED IN 1918

municipal plants and but 9% for all plants. On a two-year basis—that is, comparing 1918 with 1916—the drop in richness is more pronounced, being 24% and 25% respectively.

For the municipal plants the relative volume of grease recovered is only 10% less in 1917 than in 1916, as against 19% decrease in richness. For all plants an increase is noted. On the two-year basis, 1918 compared with 1916, the decrease in volume recovered corresponds very closely with the decrease in richness, being equal (24%) for municipal plants, and 19%, as against 25% in richness, for the total of all plants.

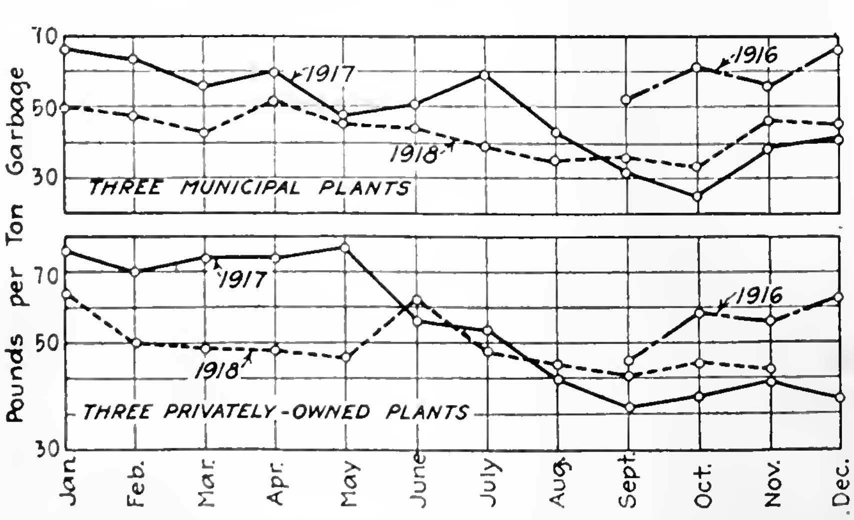
The figures for tankage recovery show surprising variation. The decrease in tankage per ton of garbage shown for the municipal plants can only be accounted for by the garbage having a greater percentage of moisture. This need not necessarily mean that a wetter garbage is being delivered, as an increase in the percentage of green material would naturally increase the moisture content and have the effect of decreasing the tankage yield. It will be noted that the volume of tankage recovered per ton of garbage is very high.

The rather low average tankage yield per ton of garbage for all plants is due to the poor recovery systems in effect at a number of such plants, and to the fact that in some instances tankage was fed to hogs while in a wet state or even pressed and used as fuel. As tankage became more valuable less wastage occurred, and it is to be noticed that the recovery increased each year.

In comparing recoveries during the periods which ended April, 1917, and 1918, collection data for which are covered in Tables I and II, the average grease recovery at five privately owned plants shows 50 lb. for the year which ended April, 1917, and but 37 lb. for the year which ended April, 1918. The reduction in richness equals 16% and the reduction in volume 17 per cent. For corresponding periods the average yield for the municipal plants at Chicago, Cleveland and Columbus was 52 lb. for the year which ended April, 1917, and 41 lb. for that which ended April, 1918. This is a reduction in richness of 21 per cent., the corresponding reduction in volume being 36 per cent. The fact that the richness in each case is higher for the municipal plants is rather surprising, each of the five privately owned plants considered having equipment equal to that of the three municipal plants named. It is believed that this difference can be accounted for by the fact that the municipal plants in every case actually weigh the material received, while in several of the privately owned plants which are considered the material treated is estimated.

A diagram shows the average grease yield per ton of garbage for three privately and three municipally owned plants. It will be noticed that in both cases the curve for 1918 begins well below that for 1917, and that the two gradually approach and finally cross. Even the last points of the 1918 curve, however, are considerably below the values for 1916.

While the curves of total production for each of these combinations of plants would show a decided break during the poor weather of last January, it is to be noticed that the January yield shows a considerable increase over that for December, 1917. The cause of this increase is probably due to bad weather, which



AVERAGE GARBAGE GREASE RECOVERY 1916-18
The three municipally owned plants at Chicago, Cleveland and Columbus are compared with three well managed privately owned plants.

caused less interference with collections in the downtown district, where richer garbage is produced, than in the outlying districts.

Curves covering the monthly tonnage reduced, the total tons of grease recovered, and tons of fertilizer tankage produced, are also given. (See diagram at the top of the next page.) Each of these curves properly ends with November, for, while blanks covering December's operations were sent out to all plants, no special effort was made to see that these were returned, and a number are still missing. The quantities handled and produced at such missing plants have been estimated and December quantities established. Such estimated quantities total 30,000 tons of garbage, 848 tons of grease and 3900 tons of tankage.

The general tendency toward conservation in food, fuel, metals, paper and other everyday commodities naturally makes the overwhelming tendency to utilize this so-called waste an outstanding feature of the year's changes in garbage disposal. Information received from various city officials indicates that no less than 40 cities of over 10,000 population have changed from some nonutilization method of garbage disposal to feeding of swine. The combined population of these 40 cities totals over 2,000,000, and their location ranges from California to New York.

In almost every instance where changes have occurred, disposal is being conducted under contract rather than by municipal forces. In one or two instances, municipal hog farms have been established, and in other cases the city has a number of feeders hauling the material collected, from some convenient central point, at a stipulated price per ton.

The year's changes from nonutilization methods to the reduction process for recovery of grease and fertilizer tankage total three, with a combined population of about 250,000. In each instance the plant established is being operated as a private enterprise.

Changes from utilization methods to nonutilization systems likewise number three, but in two of these instances the present method is due to financial difficulties, fire, etc., and these cities will very shortly be numbered among those utilizing.

The accompanying Table V gives a list of cities reporting to the Food Administration as having changed their system of garbage disposal to one of utilization. While the reported returns are official, it must be remembered that the city authorities reporting have been urged by the Food Administration to adopt utilization. It is consequently believed that in a number of instances only a portion of the garbage actually produced is being utilized. A start has been made, however, and these cities have committed themselves to a utilization method of disposal.

In addition to the tangible results indicated by the table just mentioned, there are, as further evidences of progress in garbage utilization, certain developments which should mean decreased garbage wastage during the coming year. Syracuse, N. Y., and New Orleans, La., have had garbage reduction plants authorized, and at Syracuse the plant is in process of construction; San Francisco, Cal., opened bids contemplating utilization on Jan. 20, one bid of $1.26 per ton having been obtained; Wheeling, W. Va., recently entered into contract for disposal by feeding; Norfolk, Va., Newark, N. J., and a number of other cities are considering propositions submitted to them by various corporations planning for disposal by feeding. In fact, a number of the replies being received by the Food Administration from cities not utilizing are very apologetic in tone. In a number of such cities it is reported that the garbage produced by hotels and larger institutions is being hauled away by farmers who have become interested in garbage feeding.

The amount of garbage still available for utilization is enormous, and the possibilities of further utilization of garbage include the following:

1. Due to poor separation, incineration, etc., in cities having reduction plants available, it is estimated that there are being wasted per annum 6,000,000 lb. of grease and 15,000 tons of fertilizer tankage.

2. Some 20 cities of over 100,000 population, and therefore large enough to support a reduction plant, are not utilizing their garbage. Their combined population exceeds 5,000,000, and it is estimated that 30,000,000 lb. of grease and 60,000 tons of fertilizer tankage are lost per annum. These cities, in addition, also destroy large amounts of paper, rags, etc., readily salvable.

3. The poor separation, etc., already mentioned affect the efficiency of garbage feeding farms to even a greater extent. Poor methods of handling are also very prevalent. Pork production could be increased approximately 100% by better handling in the household and on the farms.

4. Some 300 cities of between 10,000 and 100,000 population and totalling over 5,000,000 in population are wasting sufficient garbage to produce from 30,000,000 to 40,000,000 lb. of pork every year. In many instances these cities are also using fuel for disposal and wasting valuable waste paper, rags and other readily salable materials.

The year's changes from nonutilization methods mean that from 15,000,000 to 20,000,000 lb. of pork per annum will be produced from garbage formerly wasted. The changes to reduction should increase our garbage-grease production about 1,500,000 lb. per annum and our fertilizer tankage production about 3500 tons. It must be remembered that the addition of this amount of pork, grease and fertilizer will be accomplished without the use of any of our existing fats or other commercial commodities. They represent recoveries from a material formerly regarded as worthless, and wasted.

Whether the present attitude toward garbage wastage will continue, or whether the setting aside of war-time restrictions will mean a return to the old standard of

quantity and quality of garbage, depends largely on how strongly the spirit of economy and conservation has impressed itself on the public mind. The general feeling throughout the Food Administration seems to be that at least a part of the lesson that has been learned will be slow in wearing off.

Probably the low level in garbage production has been reached, grease content certainly seems to have reached a level, and any further reports on the subject of utilization should show an upward trend of both production and grease curves.

The desire to utilize all possible materials will unquestionably carry beyond the present campaign for conservation. Far more is known of the values contained in so-called waste products than before the war. Probably no inconsiderable factor, as affects garbage utilization, will be the organizations now caring for the garbage accumulating at Army camps, practically all of which is utilized. As such camps are abandoned it is believed that the men interested in these ventures will turn their attention to obtaining the garbage produced in our cities. The number still not utilizing should promise them a ready opportunity to continue along the present line of their endeavors, and the coming year should show an even greater advance in garbage utilization than 1918 has shown.

Shallow Brick Stand Up Well On Cement-Sand Base

Patching Brick on Ramps of Pennsylvania Station, New York, Shows Them to Be Worn Nearly Through Without Breaking

THE capacity of shallow vitrified brick for standing up under heavy traffic, when laid upon a cement-sand bed, is exemplified in the ramps of the Pennsylvania Station at New York, where sections eight years old were recently replaced. Investigation showed that in places the brick had worn more than half through without the top surface being shattered, although sustaining a traffic uncommonly heavy, as shown by census. The construction of these drives was noted in *Engineering Record* of Oct. 9, 1915, p. 456, and a traffic census of them in the issue of July 8, 1916, p. 54. Following is a brief description of the original construction and the replacement that has been made.

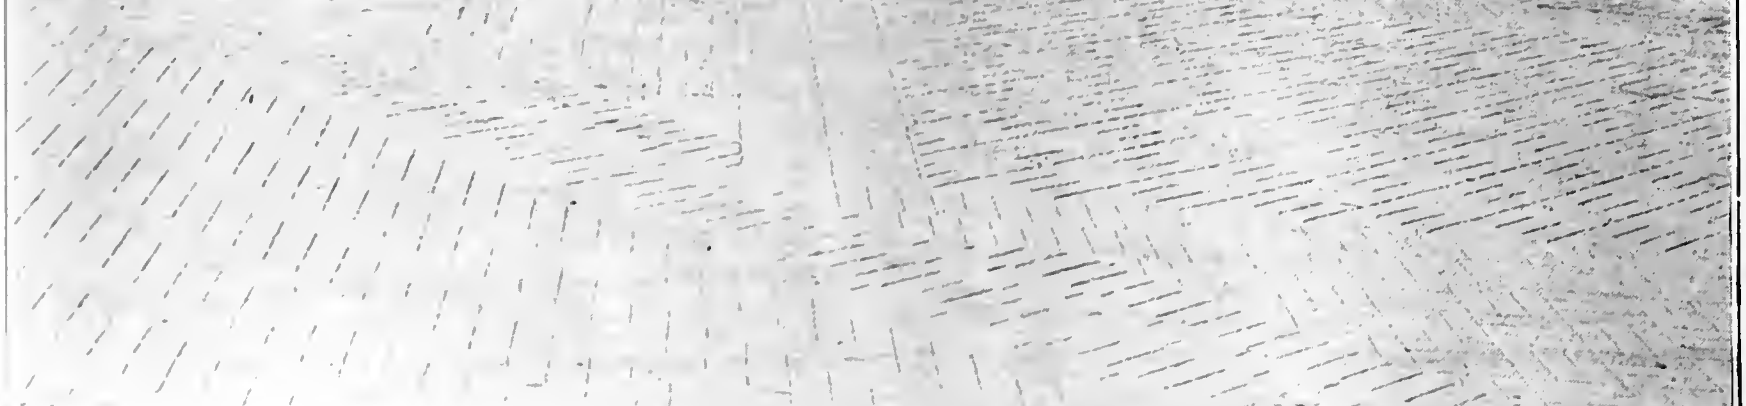
These ramps are the first pavements of any note laid in the monolithic or semi-monolithic type of construction. There had been isolated cases where brick had been laid in this manner, but there had generally been some features, such as subsequent covering with bituminous material, which made it difficult to determine the value of the construction. The ramps were laid in 1910, and when in 1914 or 1915 a controversy arose over monolithic construction, they were extensively cited as an example by those favoring that type.

To the present time there has been no information, except hearsay, as to the method of construction of these ramps, and those who favored the sand-cushion type of brick construction have expressed doubt as to the manner of laying. Now, however, the pavement having been opened, a complete description can be given.

The foundation of the pavements is of concrete and is tied in with the rest of the station. Upon this about 1 in. of cement and sand, mixed in the proportions of 1:3 and slightly moistened, was spread to form a bed for the brick. Clearfield fire-clay brick were used for the work, and were made in a special shape, being $7\frac{1}{4}$ x $2\frac{3}{8}$ in., $2\frac{1}{4}$ in. in depth. They were made without lugs, and all four surface corners were chamfered to give a hillside effect upon the grades and bring out the artistic figures in which they were laid.

Upon the cement-sand bed, the brick were laid "herring-bone" by hand, each block being bedded with a hammer to the proper elevation. A view of one of the ramps, showing the figures designed by the architect, is shown. In laying the brick care was taken to give spacing to allow for the penetration of the grout filler.

Heretofore it was supposed that the filler consisted of portland cement and fine sand, mixed in the proportions of 1:1, but examination of samples indicates that it was



BRICK WITH BEVELED EDGES LAID IN FIGURES TO GIVE ARCHITECTURAL EFFECTS

grouted with neat cement. This conclusion is also verified by statements of the contractor who did the original work and who has made the repairs. Even with the care taken to space the blocks and the use of pure cement filler, there were many jonts where the grout did not penetrate to the bottom. While the pavement was not worn through or shattered, with the exception of a few small spots, it was necessary to replace the brick at the entrance recently, on account of the repaving of 7th Ave., which necessitated a slight change in grade.

The driveways have been subjected to a tremendous traffic since being laid in 1910. The traffic census referred to above, taken in 1916, showed that 4,492 vehicles passed over the 33rd St. ramp in an average 24-hour period, while 3384 passed over the 31st St.

NEW BRICK PLACED UPON SMOOTH SURFACE OF OLD PAVEMENT SHOWS EXTENT OF WEAR

ramp. This traffic, in approaching the grade at high speed and setting the brakes, had gradually worn into the brick, as shown in the accompanying photograph, where a full-sized brick is placed on the unbroken surface. This wear was further increased by the use of sand and other means to overcome slipperiness after

NEW WORK MATCHES UP WELL WITH OLD SURFACE

the hillside effect had worn off. Examination of some of the brick which had been removed indicated that in some places even greater wear had occurred without shattering the brick. The surface at the point photographed was in excellent condition. The contention of

WHERE BRICK CONNECTED WITH NEW STREET GRADE EXTRA BED WAS NECESSARY

some that much thinner brick than is customary might be used upon monolithic and semi-monolithic types of construction is thought to be justified by the condition of these drives.

The recent replacement has been done in the same manner as the original work, but the brick are of a different make and are a deeper buff in color. The joint made with the old paving is shown in an illustration. Traffic was allowed on this surface three days after grouting, without any apparent injury, a specification which would have been considered very dangerous with the old sand-cushion type, most specifications requiring from 10 to 15 days, even with the new type.

Another view shows the extra cement-sand bed required to bring the driveways up to the new street grade. Unequal depths of sand bed were also thought dangerous in the old construction.

The work was done under the supervision of the Pennsylvania R. R. engineers, John C. Hendrickson, of New York, being the contractor for both the recent and the original construction.

Wisconsin Highway Engineer Reports Progress

A. R. Hirst, state highway engineer of Wisconsin, reports that the last quarter of last year was the best quarter in the amount of highway improvement completed.. This has been accomplished in spite of the fact that on Aug. 5 the United States Highways Council totally deprived highway construction of the principal materials used, such as cement and steel, except where priority orders had been approved. The commission had already cut down the amount of work to be done to about 40% of that previously contemplated. The total amount of construction for 1918, exclusive of Federal-aid projects, is estimated as follows: Grading, 640 miles; crushed-stone road, 110 miles; gravel road, 175 miles; concrete road, 38 miles; shale road, 25 miles; miscellaneous, 15 miles; a total of 1003 miles. Total state-aid expenditures are estimated at $2,400,000. The Federal-aid projects under construction, either by contract or day labor, total 87.36 miles, at an estimated cost of $788,300. These are in various stages of completion. Maintenance work under the new patrol system established last year has been proving very successful.

Omaha Track-Elevation Bridges Vary in Type to Meet Local Conditions

City Requirements and Topography Influence Designs—Steel and Concrete Spans Used, Some With Temporary Floors—Precast Concrete Drains on Ballasted Decks—Steel Girders Have Concrete Facing

FOUR types of bridge superstructure and different types of permanent and temporary bridge floors are included in a short stretch of track elevation on the Missouri Pacific R.R. at Omaha, Neb. This unusual variety and combination were necessitated mainly by the action of the city in making certain controlling requirements, through its engineering department. A sidehill location also introduced conditions influencing the design.

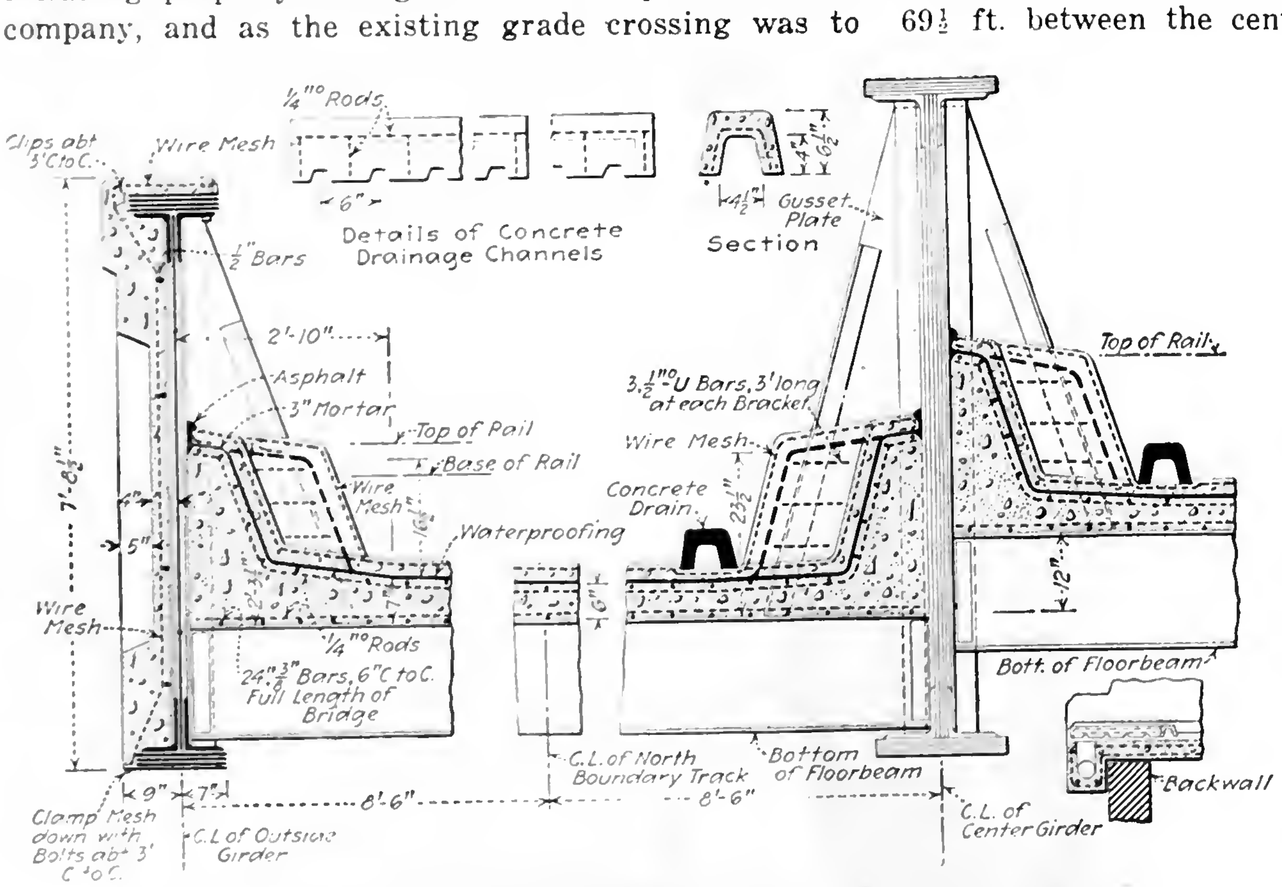
Of the three structures now built one is a steel single-span three-girder through bridge; the second is a steel single-span two-girder through bridge; the third is a three-span deck bridge having an I-beam central span flanked by concrete slab sidewalk spans. For the sake of appearance, paneled concrete facing is used on the outer or street sides of the steel girders of the first two bridges, while the third has concrete fascia girders. Ballasted decks are provided for in all cases, but, as the track elevation is to be extended later, two of the bridges have temporary, shallow, unballasted floors to provide for the grade of the present run-off inclines.

Alternative projects for elevation of the tracks and elevation of the streets were considered in the earlier stages of this problem for eliminating grade crossings, the latter plan being adopted as preferable when several streets were involved. On the west side of the city the Missouri Pacific R.R. crosses Dodge St., a main thoroughfare with a street-car line. About 10 years ago the city passed an ordinance requiring the company to build a viaduct to carry the highway and car tracks over the railroad. As the entire expense, including property damages was to be placed on the company, and as the existing grade crossing was to be left open after the construction of the viaduct, the company made objection. The matter was carried through the courts until in 1915 the United States Supreme Court gave a decision in favor of the city.

A demand for grade separation at adjacent streets had arisen in the meantime, however, and in view of this development an agreement was reached in 1916. This covered the elevation of the tracks for a distance including three streets, the elevation to be extended later as might be necessary. The cost of the work, as estimated at that time, while greater than that of the proposed viaduct for Dodge St., was less than the cost of viaducts at all three streets, which latter arrangement was undesirable from the city's standpoint. All expense had to be borne by the railroad in any case.

Conditions as to span and type of bridges were imposed by the city authorities in its approval of this new project, and several plans were submitted by the railroad before designs satisfactory to the city were perfected. Single spans were required in two cases, but intermediate bents were allowed for the third crossing. A headway of 14 ft. was required, this being considered ample for clearance of trolleys on the Dodge St. car line. All bridges are designed for ballasted decks, with E-55 loading and the Schneider formula for impact allowance.

Different levels of parallel tracks were required at the Dodge St. bridge in order to admit of carrying the slope of the street approach on the uphill side halfway under the bridge. This condition led to the adoption of a three-girder type of bridge having two independent decks at different levels. A single span of $69\frac{1}{2}$ ft. between the centers of end bearings provides for a 40-ft. roadway and two 13-ft. sidewalks. The depth of the outer girders is 7 ft. $0\frac{1}{2}$ in., while that of the middle girder is 8 ft. $4\frac{1}{2}$ in. These girders are spaced 17 ft. on centers and have framed between their webs the transverse 18-in. I-beams, spaced $18\frac{1}{2}$ in. on centers, on which the deck slab is laid. This reinforced-concrete deck slab is from 5 to 7 in. thick, covered with a four-ply waterproofing membrane of asphalt and felt, over which is a 3-in. protective layer of 1:3 mortar having wire mesh embedded near the top surface. Form boards were fitted between the top flanges of the I-beams, so that the slab does not extend below the tops of



DODGE STREET BRIDGE HAS THREE-GIRDER SPAN WITH DECKS AT DIFFERENT LEVELS

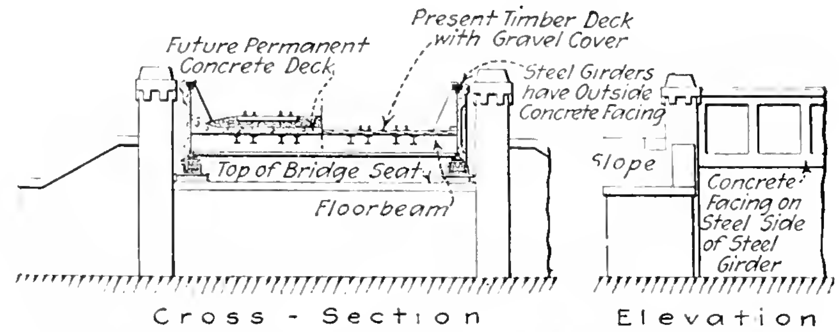
these beams. Blocks on top of the I-beams support the bottom reinforcing rods. The concrete is carried around the gusset plates, being reinforced here by horizontal stirrups or U-bars. Where the slab extends over the back walls of the abutments it rests on ⅛-in. zinc plates which permit of longitudinal movement in the expansion and contraction of the deck. The stone ballast is about 8 in. deep under the ties and is filled level with their tops.

In each deck the surface slopes toward a shallow longitudinal gutter near the central girder. In this is a precast concrete drain of inverted trough section, having slots in the edges to form inlets. This is in 6-ft. lengths, the two end lengths being closed at their outer ends. At one end of the deck is a 6-in. elbow in each gutter, opening into a precast concrete transverse drain inclosed in a rib under the end of the deck slab and lying behind the back wall of the abutment. This drain is inclined and has a screw plug at the upper end, to permit cleaning. At its lower end it discharges into a concrete downspout leading to a concrete drain on top of the footing, which in turn leads to a sewer catchbasin. These footing drains are used at all the bridges and extend the full length of the abutments and wing walls. They are slotted so as to take seepage coming through the earth fill.

Concrete masking or casing of the girders is for appearance only, and is applied therefore only to the outside of each outer girder. It has a thickness of from 4 to 9 in., and covers the top flange and web stiffeners, but not the bottom flange. The bottom cover plate extends 2 in. beyond the other plates and forms a shelf which supports the concrete and to which the reinforcing mesh is bolted. This mesh is wired to rods carried in holes in the outside web stiffeners. It is secured to the inner edge of the top flange by double-nut bolts, the lower nuts keeping it out of contact with the plates. Clips serve a similar purpose on the outer edge of the top flange.

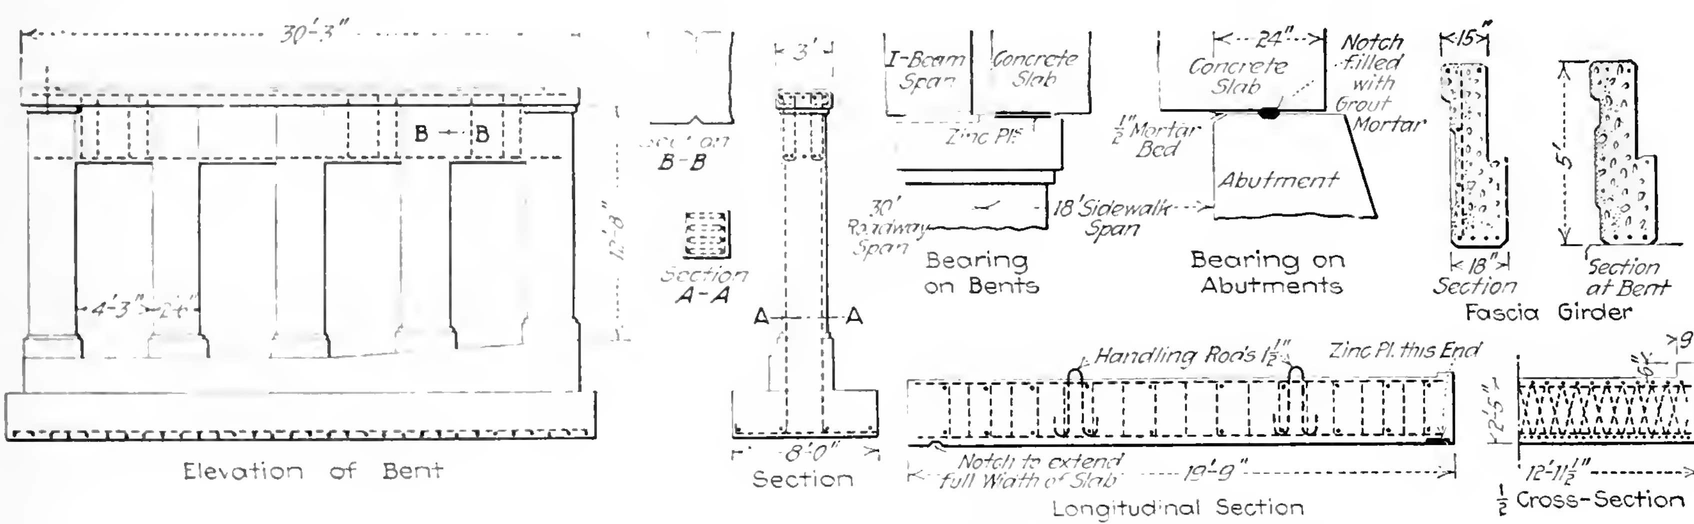
This masking concrete is a 1 : 2 : 3 mix, using a stone up to ¾ in., or sidewalk chips. It was placed in wood forms, and after their removal was finished by rubbing with carborundum bricks.

A single-span through-girder bridge is used also at Farnam St., with plate-girder floor-beams spaced 7 ft. on centers. In this case, however, there are only two girders, and these are almost 77 ft. between centers of end bearings, as the crossing is on a skew. They are 9 ft. 6½ in. deep and are masked with concrete, as described above.



FARNAM STREET BRIDGE HAS TEMPORARY TIMBER DECK TO KEEP RAILS AT LOW ELEVATION

Shallow floor construction of a temporary character is employed here, in order to keep the rail level as low as possible for the inclined run-off at the end of the track elevation. This floor has four 12-in. I-beam stringers under each track, carrying a solid deck of 6-in. transverse timbers to which the rails are spiked. Spaces between the tracks and between tracks and girders are closed with 3-in. plank. The whole deck is covered with No. 20 sheet iron and a 2-in. layer of gravel mastic. At such future time as track elevation may be extended over the next street, Leavenworth St., a concrete deck will be laid on the floor-beams and stringers, carrying ballasted track at normal grade.



DOUGLAS STREET BRIDGE COMBINES I-BEAM AND CONCRETE SLAB SPANS

An entirely different construction is employed for the Douglas St. bridge, as the city permitted the use of curb-line bents. This allowed the use of short spans, and the adoption, largely, of concrete. The bents are of concrete, having square columns spaced 6 ft. 9 in. on centers, supported on continuous footings and carrying cap girders.

For the roadway span, 30 ft. 1 in. between centers of bents, there are under each track four longitudinal 30-in. I-beams, designed to carry a concrete deck slab and ballasted track. At present they are covered with a solid 3-in. plank floor protected against cinders by a metal and mastic covering as at Farnam St. Bridge ties are laid directly on this floor, being secured to the I-beams by hook bolts.

Concrete slabs are used for the two sidewalk spans of 18 ft. 4¼ in. These were cast in place. Each span is composed of two slabs, 20 x 13 ft., 29 in. thick. Each slab is for a single track and has curbs on both sides to retain the ballast, which will be placed when the tracks are raised to grade. At present, bridge ties

are laid on six lines of 2 x 10-in. planks under each track, the planks being held in place by 2 in. of lean concrete filled between them. The ties are secured by bolts passing through outside guard timbers and anchored to the slab.

Expansion movements are provided for by ⅛-in. zinc plates embedded in the lower faces of the slabs and resting on similar plates in the cap girder of the bent. At the abutment the slab has a key registering with a groove along the top of the bridge seat, which is filled with grout and forms a key or anchor for the fixed end. The slab is made with a 1:2:4 concrete, and the bottom has 2 in. of 1:2 mortar. Its reinforcement consists of top and bottom bars with W-shaped stirrups extending the full width.

A continuous parapet slab or fascia girder of concrete extends the full length of the structure on each side, thus masking the span and deck construction. These girders are 5 ft. deep, with coping and paneled outer face. They rest on zinc sliding plates on both abutments and one bent, being anchored by dowel rods to the cap girder of the other bent.

All Foundations Are Wood Piles

The foundations of all of the bridges consist of wood piles driven to refusal, with a penetration of 20 to 35 ft. in black soil and spongy clay. These carry a load not exceeding 15 tons per pile. The concrete abutment and wing walls are of semi-gravity type, and are made with stone and of 1:2½:5 mix. The footing slabs were built first, with grooves and steel dowel rods in the top to bond with the walls. Reinforcing bars are placed in the bottom of the footings; also in the rear of the abutments and wings and in the back walls of the bridge seats. Expansion joints are made at the connections of the wings with the abutments. At the two steel bridges ornamental posts on the abutments conceal the ends of the girders.

Good appearance of the exposed surfaces of concrete was given by hand rubbing with carborundum blocks as soon as possible after removal of the forms. The part being rubbed was kept wet by sprinkling with a large brush, the rubbing and sprinkling being continued until the form marks disappeared and a film of cement was brought to the surface. This film was smoothed out or grained with a damp brush.

The grading, concrete and part of the track work were done by the List & Gifford Construction Co. The piledriving and steel bridge work, including the erection, the construction of concrete and timber decks and the concrete masking of girders, were done by the forces of the railroad engineering department. The design and the construction of the entire work were in the hands of S. L. Wonson, bridge engineer; W. R. Rhodes, assistant engineer, was in resident charge of construction. All the work was under the direction of A. E. Hadley and H. R. Carpenter, successively chief engineers of the Missouri Pacific R.R. The plans had to be approved by John A. Bruce, city engineer of Omaha.

The total estimated cost of the improvement was about $200,000, of which the cost of the three bridges, with their masonry and foundations, represented $80,000. Double-track fills form the remainder of the work.

Removing Algae from a California Irrigation Canal

Fixed Screens and Copper Sulphate Inadequate—Rotary Screen with Water Jet and Heavier Dose of Agent Used

By E. Court Eaton
Superintendent of the Lindsay-Strathmore Irrigation District, Lindsay, Cal.

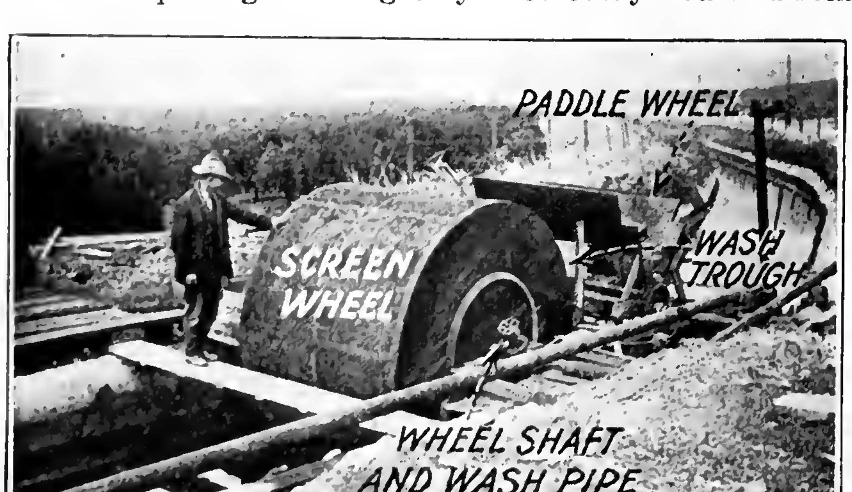
ALGÆ growths caused the Lindsay-Strathmore Irrigation District considerable trouble during the year just past, which was its first irrigation season. A brief description of the nature of these growths, and how they were overcome in large part by the use of screens and copper sulphate, may prove helpful to others.

The entire water-supply, which is obtained from wells, is carried through six miles of canal and six miles of rectangular flume, and then distributed to consumers through riveted steel pipe. All the water is metered. Even a few algæ are not permissible, as they would rapidly clog the meters or get into the consumers' service pipes, thus cutting down the flow through the hydrants and making it impossible to maintain service under uniform pressure.

The canal has a bottom width of 6.3 ft., a depth of 3.5 ft., side slopes of 1 to 1, and is gunite lined. While this is superior to a plastered lining, it has the disadvantage of leaving a rough surface which allows the algæ to grow and obtain such a hold as to reduce the velocity of the water. The flume, although also of gunite construction, was shot against forms, so that the surface exposed to the water is smooth, and comparatively little trouble with algæ has been experienced.

Water was first pumped into the canal early in April, 1918, and by the middle of May the growth had become so heavy that it began to fall off in large quantities.

Removable screens, having a ¼-in. mesh, were installed in the canal, and 0.8 lb. of copper sulphate per 1,000,000 gal. was introduced at the upper end of the canal. In spite of this, the growth so increased that by the end of May the length of time between cleaning of screens had decreased from 45 to 25 minutes. During June and up to July 20 there was less trouble, the screens requiring cleaning only once every hour. From



SCREEN WHEEL REMOVING ALGÆ FROM CANAL

this time on, however, the growth gave more trouble and up to Sept. 20 the screens were removed and replaced on an average every 15 minutes.

In August samples were taken for analysis and the results showed organisms as follows: Spirogyra, 4000

standard units per cubic centimeter; closterium, 20; penium, 40; raphidomanas, 100; amorphous matter, 1500. The predominating species was thus found to be the filamentous spirogyra, which could be killed in the continued presence of copper sulphate solution having a strength of 2.5 lb. per 1,000,000 gallons.

For the sake of convenience in operating, double this dose was introduced 12 hours of every day, commencing Sept. 15. Six days after this solution was applied, the rate of washing screens was reduced for two days to about once every hour. From Sept. 24 to 30 the rate was increased to about once every 20 minutes. Three days after the solution was introduced the algæ had commenced to die, turning brown in color, and in six days were practically all killed. The increase in cleaning screens during the latter part of the month was, of course, due to the dead algæ becoming loosened from the canal sides and falling off. From Oct. 1 to Dec. 18 little or no trouble resulted from this source, the screens requiring cleaning only once in 12 hours.

The copper-sulphate solution was introduced at a point about 20 ft. down from the beginning of the canal, and a striking indication is furnished here of the result of the treatment, for in this first 20 ft., which on account of the velocity of the water the solution does not touch, long "streamers" of the algæ are present, such as do not exist at any other point in the canal during treatment. A revolving $\frac{1}{4}$-in.-mesh screen driven by a water wheel placed in the canal was installed in an early attempt to do away with the expense of keeping a man continuously cleaning inclined stationary screens. The screen was revolved against the flow of the water in order to pick up the larger particles, which would otherwise have been rolled under it, and it was kept clean by jets of water flowing from the inside. The screen was partly successful. If made of steel with small clearances between the revolving and the stationary parts, thus preventing more of the algæ from going past the wheel it would be more satisfactory, but the principal difficulty experienced was the large quantity of water required to keep the screens clean, all of which had to be run to waste.

For dosing, a 9% solution of copper sulphate and water is mixed in a large wood tank and flows to a small orifice box alongside the canal, where the uniform head of solution is maintained over a $\frac{1}{8}$-in. orifice by means of a ball cock.

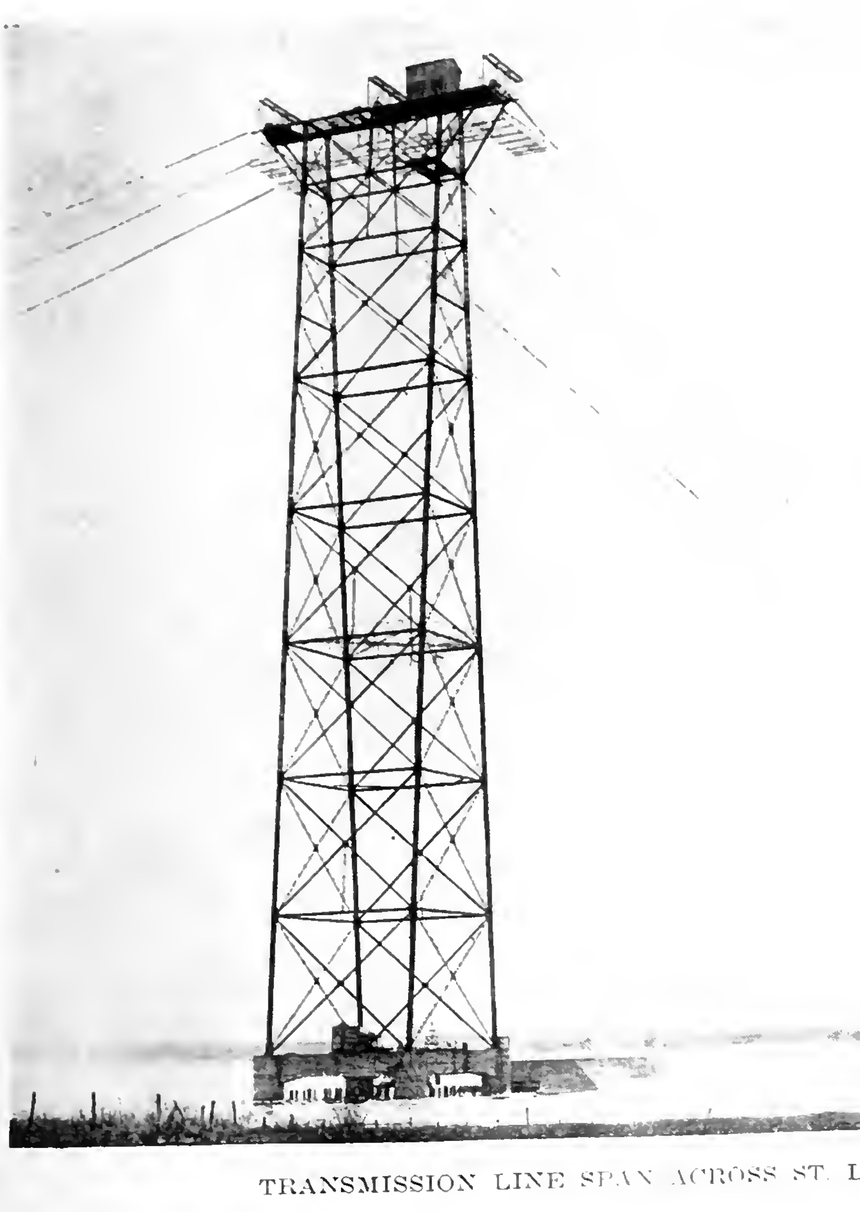
Transmission Line with 4801-Foot Span Over St. Lawrence

Longest Transmission Cable Span in World on Tower 350 Feet High Takes Place of Former Submarine Crossing

ACROSS the River St. Lawrence, about 20 miles from Three Rivers, the Shawinigan Water & Power Co. has just completed what is believed to be the longest transmission line span in the world. With a center span of 4801 ft. and anchor spans of 951 ft. and 571 ft., the total crossing is 6323 feet.

The line takes the place of an older submarine crossing, but has considerably greater capacity. It was adopted after an examination of several other competing locations, the first one of which was a three-span crossing with each span approximating 2200 ft. This simple span location, however, required considerably more land line and was also inaccessible at high-water and ice periods, so that both in cost and desirability the one-span crossing was more acceptable. There are three cables in the span, each of $1\frac{3}{8}$-in. diameter, of galvanized plough steel. Main cables were used as messengers, and the copper conductor wires were hung underneath, separated from the messengers by means of suspension insulators. The normal clearance above high water is 175 ft. The total weight of each cable is nearly 30,000 pounds.

Each end of the main span cable is attached to anchor span cables, and these anchor span cables run over the tower or large heavy double-groove sheaves 8 ft. in diameter, and are carried down to a point approximately 20 ft. from the anchor piers. At this point an equalizing arrangement is put in the line, and the load is transmitted from this point to the anchor by short straps of slightly heavier cable. Connections are in accordance with usual practice with suspension bridge cables and



TRANSMISSION LINE SPAN ACROSS ST. LAWRENCE IS NEARLY A MILE IN LENGTH

similar structures. Over the ends of the cables are placed massive steel bridge sockets having a tempered conical seat. The ends of the cables were broomed and carefully cleaned, and spelter was poured in between the wires and the sides of the seat.

The towers are of structural steel construction, and are 350 ft. high and 60 ft. square at the bases, the upstream and downstream faces tapering to a width of 14 ft. at the top. The tower foundation is made up of four circular reinforced-concrete piers 11 ft. in diameter placed on the corners of a 60-ft. square and connected by heavy reinforced-concrete beams 4 ft. wide by 8 ft. deep. These piers were sunk as hollow cylinders and afterward filled with concrete. The first 6-ft. lift of the cylinders was poured on a working platform and lowered in approximately 8 ft. of water down to the river bed, by means of 2-in. screws. The second lift, of approximately 6 ft., was then poured, and the cylinders were sunk by excavating inside with orange-peel buckets, but the lowering screws were left in place as a guide until the cylinders had reached a penetration of approximately 15 ft. From then on it was found unnecessary to use the screws. When a cylinder reached its full penetration of 40 ft. a plug of rich concrete was poured at the bottom and the inside was then filled with a leaner concrete.

The soil on which these cylinders rest on the north side is a very fine sand, on the south side a fine sand, clay and boulders. Test borings to a depth of more than 100 ft. did not show any rock. Probably rock would not be found until about 200-ft. depth was reached. In front of the foundations there are erected, as guard piers against ice, reinforced-concrete cribs filled with rock, carried up to an approximate level with the maximum recorded high water.

The erection of the cables was carried out under the direction of the engineering department by the construction forces of the company, under C. F. Saunders, general superintendent of construction. H. C. Huber was in direct charge of the job, with Thomas Burham as his assistant. The steel towers were erected by the Canadian Bridge Co. The design of the line was in charge of S. Svenningson, designing engineer of the company.

System Without Red Tape Makes Success of Day-Labor Road Maintenance

Ohio Highway Department Selects Superintendents for Ability to Accomplish Results—Employs Flexible Organization of Foremen and Patrolmen—Weekly Report Forms Show Exact Status of Each Job

FORCE-ACCOUNT maintenance and repair of Ohio roads have been used on account of the difficulty of obtaining reasonable contract prices under war conditions. System without red tape is the secret of the economic success of the plan. Reports and records are required as a certificate of results obtained, but are not permitted to pass in lieu of efficiency. "Horse sense" in the selection of superintendents has been another means of success. Technical knowledge of road-building is a requisite, but good judgment, experience, tact, and ability to get work accomplished, are equally fundamental requirements. Finally, success is clinched by a flexible organization of patrolmen, foremen and superintendents under the direction of resident and division engineers and subject to constant check and inspection by the officials of the State Highway Department. Output and quality of work are the only criteria which the department officials permit to count in passing on the performance of the repair and maintenance organization.

The procedure in organizing, directing and recording force-account operations is the conspicuous feature of the story of war-time maintenance of Ohio's state highways. Construction methods are not strikingly unusual and need no special consideration.

In every county in which the mileage of state roads warrants it, there is a definite organization for road maintenance and repair. Direct charge of field work is assigned to patrolmen, foremen and superintendents whose functions are as follows: Patrolmen are in charge of minor repairs on specified sections of road, and work alone or with one to six helpers; foremen are in charge of a gang of men, and work under the direction of a superintendent or a resident engineer; superintendents are in charge of large gangs such as would be required in resurfacing a road, or are in general supervision over several small gangs under foremen or patrolmen.

Superintendents are directly representative of the State Highway Department, but the resident engineer, who is the county representative, is their superior. Division or maintenance engineers, who work under the direction of the deputy commissioner and who have charge of many counties, direct the resident engineers.

A map of all the state roads in the county is in the resident engineer's office. On this map, original construction contracts are designated by mnemonic symbols. A maintenance section may embrace one or more construction contracts, or may be only a part of one construction contract; whichever be the case, the contract section symbols, combined or subdivided, designate the maintenance section in all correspondence, construction reports and other documents relating to the work. If, for example, a maintenance section embraces contracts A and B, it is designated as Sec. A-B; if it is a part of contract A, it is designated as Sec. A-1 or Sec. A-2.

Allotted a section for repair, the superintendent goes over the ground, determines the availability of labor and materials, and decides on the construction procedure. His duties, then, besides directing construction operations, include keeping records and making periodical reports; obtaining direct shipment of, receiving and salvaging equipment and materials; approving payments for labor and materials, and distributing expenditures.

Three records, kept by the superintendent, furnish

all information required by the highway department regarding work on any maintenance section.

The labor and rental of equipment are recorded in a time book. Each double page of this book carries a name column, date columns for 31 days, and total time, rate, amount and "remarks" columns. In entering a labor or rental item, it is designated by a symbol to indicate one of the five kinds of maintenance and repair to which distribution of cost is made. These symbols are those used in making weekly reports, as described in a succeeding paragraph. Notice that in recording time, rental of equipment is carried in the time book and is included on the payroll with labor. The time book is the first record.

All expenses incurred on the work are kept on the superintendent's cost-record sheets—one set for each maintenance section. These sheets are the superintendent's record of work done and his certificate of expenditures. All entries are made closely to date, as the sheets are the running account of the work, and are subject to call and inspection at any moment by the State Highway Department. The heading of the face of one of these sheets is reproduced; on the back are four columns for distribution of costs and a set of instructions for keeping the records. Note that both materials received and service rendered are entered, according to date. Thus, the amount of the biweekly payroll is entered on the date when the payroll is mailed to the office. So, also, entry is made of receipt of material and receipt of bill on the date received. If entries are made thus promptly and the sheets are periodically checked, any discrepancies, losses, injuries, etc., are caught and quickly rectified. Thus, the cost-record sheets are the superintendent's field bookkeeping system. When every column has been filled, he possesses a verified record of every expenditure and one that is available for any kind of cost analysis which the department may wish to make.

Check of the progress on each maintenance section is maintained by the department through weekly reports from the superintendent. These weekly reports are intended to be a complete record of all operations performed and material received. They are made in duplicate and are numbered serially. By means of mnemonic symbols, a great volume of information is recorded on a sheet. The symbols show cost distribution according to features and work items. Thus, 5 in the "hours" column followed by B-50 in the "nature of work" column means that five hours' work in painting a bridge is to be charged to bridges and culverts. Numerals indicate work items; there are 42 regular work items and 13 extra numbers for special items for which some job may call. Reproduction of a portion of the face of a weekly report sheet shows the manner of reporting labor. On the back of the sheet are columns for reporting materials received and a schedule of symbols.

Cost distribution is divided into four classes: Roadbed, surface, bridges and culverts, and equipment and superintendence. Under "roadbed" are included all expenditures incurred by the grading of roadbed, repairing shoulders and ditches, cutting brush or weeds, repairing underground drains and guard rails, removing débris from culverts, etc. Surface expenditures are all those applied to the metalled portion of the road. Expenditures for bridges and culverts need no explanation. Under "equipment," only expenditures for new equipment and tools are included; "superintendence" includes

the money paid for supervision. For example, if a foreman does some manual labor, only that part of his time given to actual supervision is charged to superintendence.

Tools and equipment are regarded truly as investments to be kept in repair and properly housed to prevent deterioration and loss and, when no longer serviceable, to be salvaged. This maintenance is the responsibility of the superintendent.

Strict account is required of all tools and equipment. Every article is marked by die or stencil; where the number of tools warrants, tool boxes are provided and, in important instances, tool houses are built. Tools are checked daily, and search for missing tools is required to be prosecuted to the limit. Loss is reported immediately to the department with a full account of the circumstances. In brief, men in the field are made aware that no carelessness will be countenanced.

It is required that tools and equipment be kept in good condition by cleaning, oiling and painting, and proper preparation and housing for storage. When broken and worn tools have accumulated in sufficient quantity they are condemned and sold by a representative of the department. If tools or equipment are moved from one county to another the superintendent lists the items on an inventory sheet, and mails this sheet to the department. If the superintendent is transferred, he reports to the department the character, number and whereabouts of all tools and equipment left by him. Only by making such a list and obtaining a receipt from the new custodian is the superintendent relieved from responsibility.

Form G 4040

IMPORTANT—A full explanation must be given of any discrepancy existing between the number of tools listed in Column No. 1 and Column No. 4. When tools are reported as having been transferred to someone else, receipt from the party receiving same must be attached to this report.

Axes—Wood,	No. of							

At regular intervals, on demand by the department, inventories are made of all tools and equipment. The department furnishes a special folder sheet of five foolscap pages, on the sides of which the equipment items are printed, as indicated by the form reproduced in part.

Except in cases of emergency, no materials or tools are purchased otherwise than through requisition by the superintendent approved by the resident engineer. Requisitions are not merely perfunctory statements of articles required. Besides exact statements of the items, a statement is required of the purpose for which they are wanted. Route and destination and rate of shipment have to be stated. Finally, a list is required of firms, particularly local firms, interested in furnishing the articles. The department does the purchasing after competitive bids are received.

Emergency purchases are of two kinds, purchases of considerable quantities and purchases of small articles and supplies. In making larger purchases, the superintendent, after he has bought, makes out a requisition specifying the goods and explaining the reason for the emergency action, and sends this requisition to the department, which issues a confirming order to the concern from which the purchase was made. To purchase small articles, the superintendent makes out a field order in triplicate, one copy for the dealer, one for the department and one for his own records.

When material has been ordered by the department, a copy of the order is sent to the superintendent, and thereafter it is his duty to see that shipments come as ordered and are cared for promptly when received. Prompt unloading is demanded to reduce demurrage, and the occasion for every bill for demurrage has to be explained. The department is kept informed concerning materials received through the weekly reports previously described.

Salvage is insisted upon. Not alone surplus materials, but containers and scrapped tools and equipment are salvaged. It is required that barrels containing road oils be tapped, and the contents so drawn off as to leave the container intact. The salvage and return of cement sacks are watched carefully. In the same way, surplus material is assembled and stored for future use. All payrolls and bills for materials, equipment and supplies are paid directly by the state. The only exception is an occasional small purchase by the superintendent, for which he pays cash and is reimbursed by the state. Payrolls are made up and mailed on the 15th and last days of the month. They are duplicates of the time book, with columns for signatures of the men and for the officials vouching for and approving the figures. Individual warrants issued by the state for the men are sent to the superintendent for distribution. Bills for materials and supplies go to the superintendent, and are checked up against his cost record-sheets, stamped "approved" and returned to the department for direct payment. Heading the department operations is Clinton Cowen, state highway commissioner. A. H. Hinkle is deputy state highway commissioner, in charge of maintenance and repair.

Telephoned from Regular Desk Phone to Airplane

Communication between an airplane in the air and a regular telephone on the Washington city line was established for the first time Jan. 16 by the Army aëronautic corps. The two links of the line were the radiotelephone from the plane, which was flying over Bolling Field, outside of the City of Washington, to a small station on the field, and the city telephone system from Bolling Field to the the office of Major General Kenly, director of military aëronautics. Conversion of radio to direct wire communication was made automatically by an apparatus devised by Army officers.

Engineering Literature

A REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Road and Street Engineers' Vade Mecum

AMERICAN HIGHWAY ENGINEERS' HANDBOOK—Editor-in-Chief, Arthur H. Blanchard; Associate Editors, Charles J. Bennett, Harold S. Boardman, Mark Brooke, William H. Connell, Walter Wilson Crosby, Arthur W. Dean, Henry B. Drowne, Austin B. Fletcher, Henry A. Gardner, Prévost Hubbard, James F. Kemp, Nelson P. Lewis, Frederick K. Morris, Joseph Hyde Pratt, John R. Rablin, Francis P. Smith, George W. Tillson. New York: John Wiley & Sons, Inc. Leather; 4 x 7 in.; pp. 1658; illustrated. $5.

Professor Blanchard and his 17 associate editors, with their unnamed "collaborators," have produced a handbook which for scope and detail of treatment within one single specialized field of engineering will probably remain unexcelled for some time. The editor-in-chief says in his preface that the volume was designed as "a reference book which would include reliable and comprehensive information on all branches of highway engineering and related subjects which would prove useful to highway officials, engineers, chemists, contractors, and engineer-salesmen of highway materials and machinery." This aim seems to have been amply fulfilled. If there be anything lacking, the reference lists of books and periodicals at the end of each of the 29 sections point the way to finding it, while for the material given in the handbook itself the General Contents, the Contents at the head of each chapter, and the 78-p. index of some 8000 entries, serve as ready guides. Another noteworthy feature of the volume is its reprinting in full of a large number of standard tests and specifications.

A detailed analysis of the volume would fill columns. A general idea of its contents is afforded by the following regrouping of sections so as to bring together the work of each editor: First, the editor-in-chief, Arthur H. Blanchard, consulting engineer, New York City, is responsible for the useful terminology, both American and British, with which the volume opens, as also for the treatment of bituminous (1) surfaces; (2) macadam, and (3) concrete. To Harold S. Boardman, dean of the College of Technology, University of Maine, fell (1) mathematics, mechanics and structural materials and (2) highway bridges, culverts, retaining walls, foundations and guard rails. James F. Kemp, professor, and Frederick K. Morris, instructor, in geology in Columbia University, dealt with engineering geology. W. W. Crosby, consulting engineer, Baltimore, treated (1) preliminary investigations, (2) brick and (3) cement-concrete pavements. Henry R. Drowne, engineer Lane Construction Co., Baltimore, handled (1) surveys and office practice, and (2) planning roads and road systems. N. P. Lewis, chief engineer, Board of Estimate and Apportionment, New York City, contributed (1) planning streets and street systems, and (2) financing highway improvements. Austin B. Fletcher, engineer, California Highway Commission, stands for grading, drainage and foundations. To Joseph H. Pratt, consulting engineer and secretary of the North Carolina State Highway Commission, was assigned earth and sand-clay roads; to Charles J. Bennett, state highway commissioner of Connecticut, gravel roads; to Arthur W. Dean, chief engineer, Massachusetts Highway Commission, broken-stone roads, and to Prévost Hubbard, chemical engineer, United States Office of Public Roads, bituminous materials. John R. Rablin, engineer, Metropolitan Park Commission of Massachusetts, covered dust palliatives, and Francis P. Smith, consulting chemical and paving engineer, New York City, sheet and rock asphalt pavements. George W. Tillson, [lately] consulting engineer to the borough president of Brooklyn, New York City, contributed (1) wood, and (2) stone-block pavements; (3) car tracks and pipe systems, and (4) comparison of types of roads and pavements. William H. Connell, engineering executive, Day & Zimmerman, Philadelphia, wrote (1) street cleaning, collection and disposal of city wastes and snow removal, and (2) organization and administration of highway departments. Mark Brooke, colonel of engineers, U. S. A., had charge of sidewalks, curbs, gutters and highway signs. Finally, the section on the preservation of materials used in highway structures was proposed by Henry A. Gardner, assistant director of the Institute of Industrial Research, Washington.

The volume contains many convenient tables and diagrams. Particular mention may be made of those giving external and skew distances for 25-ft. radii, arcs for 100-ft. tangents, and deflections for 100-ft. arcs. These should be very useful in compiling final staking-out notes, and also for preliminary locations, except that as for the latter the volume is too large and unwieldy for field work.

The bulkiness of the volume is in part due to an attempt to pack into a single volume as much as possible of every subject the highway engineer would ever wish to know about. The sections on mathematics, engineering geology, planning streets and street systems, and street cleaning and waste disposal, to name only four, contain material which but few highway engineers will ever have occasion to use. The paragraph describing an incinerator for mixed refuse sounds like the unrealized dream of an inventor. It certainly fails to give an idea of any incinerator ever put into common use.

The wonder grows how publishers of engineers' handbooks can continue to give increasing amounts of information prepared by specialists—in fact, nothing short of a whole series of monographs between one pair of covers—without doubling or trebling the price charged for the earlier reference works. May the time not yet come when the practice, like the street-car ride of almost unlimited length for a nickel, will break down of its own weight? Meanwhile, purchasers of handbooks need not complain, unless they would prefer less bulk at a lower price.

Formula Charting

Reviewed by ROBERT C. STRACHAN
Civil Engineer, New York

GRAPHICAL AND MECHANICAL COMPUTATION—By Joseph Lipka, Ph.D., Assistant Professor of Mathematics in the Massachusetts Institute of Technology. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth: 6 x 9 in.; pp. 264; illustrated. $4.

The author of this volume has produced a treatise that is admirable not only for its clarity of diction and logical sequence of ideas, but also because it sets before the general scientist and the engineer principles and processes of the greatest practical utility, which heretofore have not been easily accessible in their entirety. Those who were interested have found it necessary to gather from scattered sources the matter here brought together in a form adapted to the use of practitioners as well as students.

The English bibliography of formula charting is decidedly limited; much of the discussion on methods of forming empirical curves to fit experimental data must be searched out in the proceedings of scientific societies and the contents of scientific periodicals here and abroad; and of the many explanations of the well known slide-rule principle but few contain any attempt to link up that principle with more general conceptions.

Professor Lipka has brought between two covers a well executed presentation of all these related subjects. It should not be understood from this statement that the book is merely a compilation, for it is decidedly not, in the usual sense. The author has summarized and correlated the work of many others, intermingling an amount of his own that is by no means negligible.

In the opening chapter are set forth the elementary principles of the representation of functions by scales, followed by the extension of these principles to include the so-called Mannheim slide rule, the log-log slide rule and others; after which the author proceeds to the graphical solution of equations containing two or more variables, and thence to the subject of nomographic or alignment charts. Probably there is at present no other work in English in which this subject is treated with equal comprehensiveness. Runge, it is true, has devoted some attention to it in his "Graphical Methods," but in so perfectly generalized a fashion that his reader may easily fail to see its true bearing; while the excellent work of Professor Peddle is more restricted in scope.

Professor Lipka's method resembles quite closely that of Maurice d'Ocagne. His underlying theorems are demonstrated in full, and his charts worked out to completion. To many they will be a surprising revelation of the possibilities of graphical methods in enabling one to avoid the drudgery of numerical computation.

The formulas selected for manipulation are typical ones, and similar methods may be applied readily to many others which will suggest themselves to the reader, as bearing on his particular kind of work.

In the highly enlightening chapters on the building of empirical formulas, the interpreting of experimental data and graphical interpolation, the author enunciates the criteria by which to determine the species of curve giving the best representation of a given set of data, and shows in detail, for a large number of actual experimentation reports, the practical processes of deriving such curves and evaluating their constants. The author's well considered order of presentation now becomes apparent, for the reader will at this point realize that, however complicated may be the representative curve with which he has to deal, he is prepared to devise some form of chart by which its equation may be rapidly solved.

The final chapter contains a very lucid exposition of the principles of graphical and mechanical differentiation and integration, leading naturally to the description and analysis of the planimeter, the integraph and the differentiator with which the book closes.

At the end of each chapter are given problems, the solution of which will be of great benefit to students. The illustrations are numerous and well rendered, the typography is of a pleasing clearness. The index is proof that the author has not lost sight of the practical needs of the reader. The book deserves the highest success.

Bettering Municipal Government

OUR CITIES AWAKE: Notes on Municipal Activities and Administration—By Morris Llewellyn Cooke, M. E., Consulting Engineer, Formerly Director of Public Works, City of Philadelphia; With a Foreword By Newton D. Baker, Secretary of War, Formerly Mayor of Cleveland. New York: Doubleday, Page & Co. Cloth; 6 x9 in.; pp. 347; illustrated. $2.50.

Concerned largely with experiences in Philadelphia while the author was Director of Public Works in the reform Administration of Mayor Blankenburg, and drawing also upon the author's observations on business efficiency and municipal government before and since then, this volume contains much which should be a help and inspiration to those who wish to improve the municipal government of any city, large or small.

Owing to an apparently haphazard presentation of the many topics discussed, it is difficult to give, without undue detail, a clear idea of the contents of the volume. After a few pages about service to citizens and some observations on encouraging the people to make complaints, the book plunges into budgets and appropriations, then as suddenly takes up "contract jockeying" and "political assessments." Next came chapters on some phases of the framework of government, the science of management, and "The One Best Way." The chapter last named opens with remarks on "coöperation with the people," but deals mostly with standardization. Succeeding chapters take up public servants in general, the civil service, publicity and utilities. Then comes a chapter, entitled "The City as an Ally of Industrial Progress," which has to do with markets, civic centers, public parks and baths, business men's associations, commercial and vocational guidance, and other subjects. The two final chapters consider similar topics, and touch again upon some of the earlier ones.

The value of the book lies chiefly in its accounts and interpretations of the author's personal experiences as Director of Public Works and the knowledge thus gained of Philadelphia misgovernment under earlier administrations. Useful also are comments on some phases of scientific management and on the newer experiments in municipal government, such as the commission and manager plans. The discussion of civil service, under the heading "Finding the Man in Ten Thousand," is perhaps the most valuable part of the book—at least for the readers of this journal. The part of this chapter which considers the selection of

men for "$3000 plus" positions deserves wide attention. The most pungent chapter is "Our Utilities and Their Owners." Here the author says many sharp and some harsh things, most of which have at least some warrant in view of the extent to which utility exploitation has been carried in this country. Strong expressions and even some bias may be expected from any writer discussing utilities from the public viewpoint, but Mr. Cooke seems to show an unwarranted excess of bias, particularly toward engineers in general who have served on the side of the utility companies in valuation and rate cases. True, he points out that our whole system of expert testimony in court practice begets partisanship instead of a devotion to truth, but that does not warrant classing all who testify for utility companies as, by that fact, venial, any more than it warrants sweeping condemnation by the private interests of those who testify on the city's side, as has been done more than once by men who ought to be above such extreme partisanship.

The book has no index. This, and the fact that some of the chapters and the book as a whole are literary medleys, may seem surprising in a volume written by an exponent of scientific management, but the book does not pretend to be a scientific treatise, and despite its scrap-book tendency it is bound to have a salutary effect as a source of inspiration for better municipal government.

Utility Rates

REVIEWED BY FREDERIC P. STEARNS

Consulting Engineer, 1 Ashburton Place, Boston, Mass.

PUBLIC UTILITY RATE FIXING—By C. E. Grunsky, Eng. D., Consulting Civil Engineer, M. Am. Soc. C. E., President, American Engineering Corporation, President, California Academy of Sciences, Etc. San Francisco: Technical Publishing Co. Cloth; 6 x 9 in.; pp. 169; illustrated. $2.50.

A number of articles dealing with the problem of fixing public utility rates and with related matters, originally contributed to the *Journal of Electricity*, have been assembled in this volume. One of the articles, entitled "Fair Value and the Rate Base," was written by Capt. C. E. Grunsky, Jr.

To a large extent the book reiterates the views expressed by the author in his book entitled "Valuation, Depreciation and the Rate Base" (reviewed in *Engineering News*, March 15, 1917) and in other previous writings. As a rule, the changes made are not along the lines indicated by the most important court decisions and by the present practice of valuation engineers, public service commissions and progressive corporations.

The author makes frequent reference to his view that it is illogical to make value which results from earnings the basis of rates, and objects to the use by valuation engineers and public service commissions of "value" as a rate base, not noting that the so-called "value" used by them is not deduced from earnings but is obtained in nearly the same way as the author's rate base, the important difference being that the author would not deduct accrued depreciation.

He also gives prominence to the view "that accrued depreciation is not an element for consideration when rates are to be fixed," and that annual or accrued depreciation need not be determined. Instead of the latter, he would substitute in fixing rates an indefinite "replacement requirement," which is apparently a yearly sum for each plant unit that with interest would be sufficient to replace the unit at the end of its probable life, or, as an alternative, the amount actually required for replacement in a given year. To use his own words (p. 152), the replacement requirement "would have to be approximated on the basis of past experience, and would naturally be so distributed over a series of years, preferably in anticipation of the requirement, that rates once established would not have to be modified too frequently. It will be immaterial how the requirement is ascertained. Any method of procedure which will fairly approximate the desired result will suffice."

The importance of annual depreciation in determining rates is best indicated by an actual example. The Bell telephone system of the United States in 1917 earned, in round numbers, for depreciation $53,000,000, and for current maintenance $41,000,000. The depreciation item is larger than that for dividends. Were the telephone companies to accept the author's views in regard to replacement requirements as a substitute for depreciation, the amount to be earned for this item at the higher rate which the author has suggested would be many millions less than the present sum for depreciation, and at the lower rate by far the larger part of the item would be eliminated. In the latter case, it is sometimes asserted that as the depreciation is not collected as it accrues the future ratepayers are under obligation to pay it at a later date, but as the Supreme Court in the Knoxville case has ruled that "it is the duty of corporations to exact sufficient returns to keep the investment unimpaired," it is not likely that any such obligation would be recognized.

In regard to determining the annual return after having determined the rate base, the author deals at considerable length with the legitimate earnings on invested capital, holding that there should be a proper interest return and a profit, this profit to be made up of compensation to the owner of the property for hazard, for management, and as his share in the general prosperity of the community. He introduces the view that this profit should be a percentage upon the gross earnings and not upon capital.

There are chapters relating to the appraisal of real estate adapted for special use, to the determination of the value of real estate in eminent-domain proceedings, to the value of water rights, and to the rate of return, which contain decisions on some of these matters as given in San Francisco water-rate cases recently decided; also a chapter relating to the rate schedule.

Methods and Economics of Storing

STORING: Its Economic Aspects and Proper Methods—H. B. Twyford, Otis Elevator Co., Author of "Purchasing: Its Economic Aspects and Proper Methods." New York: D. Van Nostrand Co. Cloth; 6 x 9 in.; pp. 196; illustrated. $3.50.

Intelligent storing bulks large in the success of manufacturing and mercantile operations. Numerous factors such as fluctuation in prices, rise and fall in demand and continuity of production, must be carefully integrated by the successful storekeeper. Besides these, the technique of storekeeping, such as storeroom location and equipment, storeroom appliances and accounting methods, must be known. Finally, the storekeeper must have a keen perception of the fact that storing is a

definite and important expense in the conduct of a business. Both the economics and the technique of storing are well presented in Mr. Twyford's new book.

Of the 12 chapters, three discuss the economics and outline the principles of storing. The fourth chapter presents the exceedingly important question of precise designation of stored articles by standard definitions and specifications. Five subsequent chapters discuss the location and arrangement of storerooms, storeroom equipment and appliances, and storeroom accounting and record-keeping methods. Organization of the stores department and the functions of the various employees are outlined in Chapter IX. The processes of receiving into and delivering from stores are described in the final two chapters. Nearly a hundred illustrations of equipment, appliances and bookkeeping and inventory forms add materially to the value of the volume.

A Great American Engineer

GEORGE WESTINGHOUSE: His Life and Achievements—By Francis E. Leupp. Boston, Mass.: Little, Brown & Co. Cloth; 6 x 9 in. pp. 300; illustrated. $3.

Since Smiles wrote his famous "Lives" sixty years ago, biographies of engineers have been few. Smiles wrote of British engineers. Except for sketches and two or three more ambitious attempts, the lives of American engineers have heretofore gone unrecorded. Hearty welcome, therefore, to Mr. Leupp's well-rounded and readable story of one of America's great inventors, engineers and captains of industry.

After touching on Westinghouse's boyhood, Army and Navy experience in the Civil War, and three months' uninterested trial of "the French and German languages, solid geometry, and English rhetoric, essays, and vocal training" at Union College, the author starts with Westinghouse's career as inventor and manufacturer—already foreshadowed by a rotary engine which he built before going to war. A car replacer, suggested by a tedious wait due to a train wreck, was his first commercial venture. With this he made and marketed cast-steel reversible railway frogs. Marvelous successes with the railway air brake, alternating current and other electric developments—lighting the Columbian Exposition, elevated-railway electrification, Niagara power—the introduction of natural gas, the gas engine and the steam turbine, are all told. A good idea is given of the variety and magnitude of Westinghouse's manufacturing operations and his masterful control of their organization and financing up to the receivership of the Westinghouse Electric & Manufacturing Co. in 1907. The home, social and other personal relationships of Westinghouse are briefly presented.

The book is addressed to the nontechnical reader, but its engineering detail is sufficient for most engineers who are not specialists. In his preface the author says:

> One day, let us hope, we may have from the pen of some well known expert in technology an adequate summary of what the whole world's industrial advancement owes to the work of the eminent inventor. The mission of the present volume is simply human. It will have been accomplished if it conveys to the young man of today a sense that his career will depend for success less on the splendor of its start than on the spirit in which he pursues it; far less on capital than on courage, on worry than on watchfulness, on "pull" than on perseverence.

Until the experts in technology, as Mr. Leupp calls them, find time and courage—and perhaps we should say gain skill—to write biographies, we shall have continued reason to be grateful to the Smiles and Leupps who portray the "human" side of engineers. May their tribe increase!

A South American On Retaining Walls

RETAINING WALLS: Based Entirely on the Theory of Friction —By Pedro J. Dozal, C. E., Escuela Nacional de Ingenieros de Mexico. Done into English by R. T. Mulleady, B. Sc. Eng. (Birmingham). The Author, Buenos Aires. Cloth; 7 x 10 in.; pp. 155; illustrated.

On the whole, this book is an earnest and sincere, though labored, attempt to analyze earth pressure. The author's basic method of attack is to determine, from some sliding wedge, the force component parallel to the plane of slip, or, in the author's terminology, the plane of condition. This component is in part neutralized by the frictional resistance along this plane of condition. The remaining part of the component is termed the "unbalanced force." The maximum value of this unbalanced force, and also the maximum value of its horizontal and vertical components, are determined by the ordinary processes of the differential calculus. In a "coherent" mass it is assumed that in addition to the frictional resistance there is also a shearing resistance along the plane of slip, and it is the aim of the analysis to find the plane of minimum resistance. The thrusts found are considerably less than those given by Rankine's and Coulomb's methods. The author ignores any frictional resistance between the wall and the earth.

Fundamentally, the author has failed to notice that the maximum wedge of displacement does not always produce the maximum thrust upon the wall. It is essential to find what impending wedge of displacement produces the maximum thrust upon the wall. This is done by the method given by Coulomb, with the elegant graphical scheme of Poncelet.

From the matter contained in the book, it appears that the author is unfamiliar with the large mass of modern literature on the subject. Levy, Boussinesq and Resal of France and Cain of America have compiled a vast amount of information on earth pressures covering every possible condition and making parallel comparisons with experimental data.

In his preface the author says that "no writer has investigated as to whether a plane cutting an homogeneous and strongly coherent solid receives any pressure from that solid." The facts are quite the reverse. The lateral displacement of solids due to vertical loading forms an important basis of the theory of elasticity and is given by the classic "Poisson's Ratio." Again, on p. 25, after an intricate explanation quite lacking in rigor, it is stated as proved that the surface of rupture for a coherent mass is a plane. Experiment easily demonstrates that such a surface is not a plane, and careful mathematical analysis has shown the same—see, for example, Resal, "Poussée des Terres," Part II, and Cain, "Earth Pressure."

Although the book is entitled "Retaining Walls," it is, like a number of other books unhappily so named, a dissertation on earth pressure, with a minute appendage on gravity masonry walls containing nothing

of novelty. The book in itself is interesting in its carefully developed algebraic analysis; however, it is universally conceded that the action of earth masses has exhausted the efforts of mathematical and engineering science, and it has been shown that when retaining walls fail they rarely do so because of faulty earth pressure theory but generally because of faulty wall or foundation details.

Municipal Ownership Under the Microscope

THE RESULTS OF MUNICIPAL ELECTRIC LIGHTING IN MASSACHUSETTS — By Edmond Earle Lincoln, M.A (Oxon.), Ph. D., Instructor in Economics, and Tutor in the Division of History, Government and Economics, Harvard University. Boston and New York: Houghton, Mifflin Co. Cloth; 5 x 8 in.; pp. 478; illustrated. $3.

In his painfully laborious study, which appears to be almost as painfully conscientious in its attempt at impartiality, Mr. Lincoln may be said to have put municipal ownership of electric-light plants in Massachusetts under the microscope. So minutely detailed are the facts and figures, and so many are the qualifications after a general conclusion has been drawn, that nearly 500 closely printed though typographically clear pages are filled.

There is no denying that the study is a valuable one, for besides the internal evidence there is the testimony that it won a $1000 prize which is not lightly awarded. Whether the same amount of effort, directed in some other of many possible channels of investigation, would not have proved more beneficial to humanity in general and to the author in particular—barring possibly the $1000 price—we shall leave to the judgment of the author—say a quarter century hence—with little doubt in our minds what his conclusion will be.

Not for the sake of contrast, but to throw light upon municipal ownership results, the author selected for comparative study privately owned plants of as nearly like character as feasible. This, he thinks, put private ownership to a disadvantage, because the smaller private plants are under a handicap as compared with the larger private plants. But if one looks beyond Massachusetts does not this argument work both ways? However, the study was—and that, too, for good and sufficient reasons—confined to Massachusetts, which enjoys the distinction of having begun state regulation of gas and electric lighting long before any other American commonwealth did, and which put the municipally as well as the privately owned plants under the control of the commission.

After a short introduction, the author presents a sharply critical survey of the literature on municipal electric lighting in the United States. We leave those castigated to defend themselves as best they can. Then comes an illuminating review of the work of the Massachusetts Gas and Electric Light Commission, and then an outline of the author's plan for his main task. The body of the book is devoted to minute analyses and comparisons of the recent physical and financial statistics of the 39 municipal and the 33 selected private plants, and to observations based on local personal surveys or examinations of some of the plants. The plants studied were divided, under each class of ownership, into those generating and those buying their current—the plants serving as mere distributors of current being a large percentage under each class of ownership. Each chapter has a series of numbered conclusions—a welcome and almost necessary feature in so detailed a volume, with its running conclusions and their qualifications. A chapter of general conclusions, 10 pages long, sums up the whole investigation. There are 18 pages of references and a statistical appendix of 44 pages.

The main conclusions of the author, while in many respects favorable to the municipal electric light plants studied, are adverse to municipal ownership. Whatever advantages the plan may seem to have produced in Massachusetts the author thinks are offset or nearly offset by disadvantages, and the consumers under private ownership have been so well protected by the Gas and Electric Light Commission that the risks of municipal ownership seem to the author to be quite unwarranted. These risks, he thinks, are looming up in the future, as the plants become older, and in view of the growing tendency for small plants to buy instead of generate their current.

The book would have been clearer and stronger had the author set up a few main standards before starting his general discussion, and consolidated and measured his multitudinous conclusions against them. Moreover, with all his infinite labor and pains, he has done little to show how the consumers and taxpayers directly concerned feel towards municipal ownership. Instead, he sets up his own dicta as to how they should or at least might feel. The balance against municipal ownership—if such it can be called—found by the author does not seem to be so large that the people of the 39 Massachusetts communities concerned might not gladly shoulder it for the sake of whatever satisfaction they may take in owning and managing their electric lights.

The officials and citizens of any community which is considering municipal ownership, whether of electric light or other utilities, or which is in doubt as to the wisdom of continuing to operate a given utility, might well read this book—following in most cases the author's suggestions for judicious skipping of much of the detailed discussion.

Finding and Recording Costs

COST ACCOUNTING—By J. Lee Nicholson, C. P. A., Instructor Cost Accounting, Columbia University, 1912-16; and John F. D. Rohrbach, C. P. A., Instructor Cost Accounting, Columbia University. New York: The Roland Press Co. Leather; 6 x 9 in.; pp. 576; illustrated. $6.

The demand for production cost figures and the improvements in accounting procedures have grown to such an extent in the past few years as to lead to the expansion of the senior author's "Cost Accounting, Theory and Practice," published in 1913. Besides describing the general methods of cost finding, factory routine, the summarization and control of cost records and the installation of a cost system, the author deals at some length with cost-plus contracts. He makes especial reference to the problems and difficulties that have arisen in interpreting the terms of the numerous Government contracts made during the war period, and their cancellation. He also includes a detailed discussion as to what may be chargeable to such contract work. There are separate chapters on materials, wage systems, labor reports and depreciation.

Publications Received

[So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be obtained without cost, at least by inclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or in case of books or papers privately printed, then to the author or other persons indicated.]

AMERICAN PROBLEMS OF RECONSTRUCTION: A National Symposium on the Economic and Financial Aspects—Edited by Elisha M. Friedman, with a Foreword by Franklin K. Lane, Secretary of the Interior. New York: E. P. Dutton & Co. Cloth; 5 x 8 in.; pp. 464; illustrated. $4.

APPLIED MECHANICS—By Charles E. Fuller, S. B., and William A. Johnston, S.B., Professors of Theoretical and Applied Mechanics, Massachusetts Institute of Technology. Vol. II, Strength of Materials. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 556; illustrated. $3.75 net, postpaid.

ATLANTIC INTRACOASTAL CANALS: Report of the Bureau of Foreign and Domestic Commerce on Deep Sea-Level Canals Connecting Massachusetts Bay and Buzzards Bay, New York Bay and Delaware River, and Delaware River and Chesapeake Bay. Washington, D. C.: Department of Commerce. Paper; 6 x 9 in.; pp. 139; illustrated.

BOARD OF PUBLIC UTILITY COMMISSIONERS: Statistics for 1917—Trenton, N. J.: The Commission. Paper; 6 x 9 in.; pp. 48.

Shows assets, liabilities and income accounts for privately owned steam and electric railways, and gas, electric, water and sewer companies, having revenues of more than $10,000 in 1917.

BUILDING CODE, STATE OF WISCONSIN, REVISED 1918—Madison Wis.: Industrial Commission of Wisconsin. Paper; 6 x 9 in.; pp. 120; illustrated.

This code was originally issued in 1914 and revised in 1915. The present edition contains "a few necessary changes," based on experiences of the past three years "in the requirements for fire protection, sanitation and structural safety in the construction of buildings in this state.

CENTRAL STATION HEATING: Its Economic Features with Reference To Community Service—By John C. White. Washington, D. C.: Bureau of Mines. Paper; 6 x 9 in.; pp. 23; illustrated. 5c. from Superintendent of Documents.

CONVEYANCE AND DISTRIBUTION OF WATER FOR WATER SUPPLY: Aqueducts, Pipe-Lines and Distributing Systems—A Practical Treatise for Water-Works Engineers and Superintendents—By Edward Wegmann, C. E., M. Am. Soc. C. E., American Water-Works Association, New England Water-Works Association. New York: D. Van Nostrand Co. Cloth; 6 x 9 in., pp. 663; illustrated. $5.

DRAFTING-ROOM METHODS—STANDARDS AND FORMS: A Reference Book for Engineering Offices and Draftsmen—By Charles D. Collins, M. Am. Soc. C. E. New York: D. Van Nostrand Co. Cloth; 6 x 9 in.; pp. 149; illustrated. $2.

EXTINGUISHING AND PREVENTING OIL AND GAS FIRES—By C. P. Bowie. Washington, D. C.: Bureau of Mines. Paper; 6 x 9 in.; pp. 50; illustrated. 20c. from Superintendent of Documents.

THE FOUNDATIONS OF NATIONAL PROSPERITY: Studies in the Conservation of Permanent National Resources—By Richard T. Ely, Professor of Political Economy in the University of Wisconsin; Ralph H. Hess, Associate Professor of Political Economy in the University of Wisconsin; Charles K. Leith, Professor of Geology in the University of Wisconsin, and Thomas Nixon Carver, David A. Wells Professor of Political Economy in Harvard University. New York: The Macmillan Co. Cloth; 6 x 9 in.; pp. 378; illustrated. $2.

GASOLINE AND KEROSENE CARBURETORS: Construction—Installation—Adjustment—By Victor W. Pagé, M. S. A. E., Author of "The Modern Gasoline Automobile," "Automobile Repairing Made Easy," "Aviation Engines," etc. New York: The Norman W. Henley Publishing Co. Cloth; 5 x 8 in.; pp. 206; illustrated. $1.50.

This book will interest owners and drivers of automobiles and auto trucks because it is a practical treatise on fuel economy and deals comprehensively with the subject of kerosene for fuel.

HANDBOOK ON EMPLOYMENT MANAGEMENT IN THE SHIPYARD Dealing with Modern Methods and Practices of Employment Management. Bulletin II, The Employment Building. Philadelphia, Pa.: U. S Shipping Board Emergency Fleet Corporation. Paper; 8 x 10 in.; pp. 29; illustrated.

HEALTH ALMANAC FOR 1919—Compiled by R. C. Williams, Assistant Surgeon, U. S. Public Health Service. Prepared by Direction of the Surgeon General. Washington, D. C.: U. S. Public Health Service. Paper; 6 x 9 in.; pp. 13; illustrated.

IOWA ENGINEERING SOCIETY: Proceedings of Annual Meeting held at Waterloo, Feb. 20-21, 1918 Iowa City, Iowa: The Society. Paper; 6 x 9 in.; pp. 169; illustrated. 50c.

JOURNAL OF THE BOSTON SOCIETY OF CIVIL ENGINEERS: Proceedings, Nov., 1918—Boston, Mass.: S. Everett Tinkham, Secretary and Librarian. Paper; 6 x 9 in.; pp. 35; illustrated. 50c.

LOGARITHMS OF HYPERBOLIC FUNCTIONS TO TWELVE SIGNIFICANT FIGURES—By Frederick E. Pernot and Baldwin M. Woods. Berkeley, Cal.: University of California. Paper; 7 x 10 in.; pp. 170.

The range covered by these tables is from 0.000 to 2.000, with a tabular interval of 0.001. For the entire range the sinh, cosh, and tanh are given. For the first quarter of this range—namely, up to 0.500—values of log sinh x/x and log x/tanh x are given, also to the interval of 0.001. Other high-precision tables of hyperbolic functions do not give figures below 0.500, and thus an essential need is provided for by the present work. An introductory text explains the method of calculating the tabular values.

METHOD OF LEAST SQUARES APPLIED TO ESTIMATING ERRORS IN COAL ANALYSIS—By J. D. Davis and J. G. Fairchild. Washington, D. C.: Bureau of Mines. Paper; 6 x 9 in.; pp. 36; illustrated. 5c. from Superintendent of Documents.

MINERS' SAFETY AND HEALTH ALMANAC, 1919—Compiled by R. C. Williams, Assistant Surgeon, U. S. Public Health Service. Washington, D. C.: Bureau of Mines. Paper; 6 x 9 in.; pp. 48; illustrated.

Among other subjects, takes up communicable diseases and general health of miners, water-supply, garbage and sewage disposal and has seven pages on sanitary privies, with illustrations. 5c. from Superintendent of Documents.

MUNICIPALITIES AND COUNTIES OF CALIFORNIA: Annual Report for 1917 of Financial Transactions. John S. Chambers, State Controller, Sacramento, Cal.: The Controller. Paper; 6 x 9 in.; pp. 219.

NATIONAL BRICK MANUFACTURERS' ASSOCIATION: Report of 32nd Annual Convention—Indianapolis, Ind.: The Association. Paper; 6 x 9 in.; pp. 192.

NATURAL GAS: Its Production, Service and Conservation—By Samuel S. Wyer, Columbus, Ohio. Washington, D. C.: Smithsonian Institution. Paper; 6 x 9 in.; pp. 67; illustrated.

PROBLEM OF STREET CLEANING, ROCHESTER, N. Y.: Report Submitted to the Mayor and to the Commissioner of Public Works. Rochester, N. Y.: Rochester Bureau of Municipal Research, Inc. Paper; 6 x 9 in.; pp. 133; illustrated.

This thoroughgoing study of local street-cleaning methods and needed reforms follows a similar investigation and report on snow removal, and will be followed in turn by a report on refuse collection. The street-cleaning study was made by John T. Child, assistant engineer, working under James W. Routh, chief engineer of the bureau named, and the report was written jointly by the two and finally edited by L. E. Snyder, director of the bureau. It is a good example of the excellent work being done by the best bureaus of municipal research.

THE REGULATION OF PRIVATE WATER COMPANIES IN NEW YORK CITY—By Delos F. Wilcox, Ph.D., [lately] Deputy Commissioner of Water-Supply, Gas and Electricity, City of New York. New York: The Author. Paper; 6 x 9 in.; pp. 24.

RECREATION USES ON THE NATIONAL FORESTS—By Frank A. Waugh, Collaborator; 1918. Washington, D. C.: U. S. Department of Agriculture. Paper; 6 x 9 in.; pp. 43; illustrated.

REPORT OF WATER RIGHTS BRANCH OF THE DEPARTMENT OF LANDS, PROVINCE OF BRITISH COLUMBIA, for 1917. The Hon. T. D. Pattullo, Minister; William Young, Comptroller. Victoria, B. C.: The Department. Paper; 7 x 10 in.; pp. 58; illustrated.

A report on water power and water-supply in the several districts of the Province of British Columbia; including a table giving revenue for the year and records of precipitation from various meteorological stations. The appendices give a list of 270 power sites of 500 hp. and over, of which 30 are wholly or partially developed, 93 sites applied for, and 147 known and unstaked; also instructions on how to acquire license to take and use water. There are also included data useful in measurement of water and the design and operation of water-supply structures.

THE SAFETY MOVEMENT IN THE IRON AND STEEL INDUSTRY, 1907-17—By Lucian W. Chaney and Hugh S. Hanna. Washington, D. C.: Bureau of Labor Statistics. Paper; 6 x 9 in.; pp. 299; illustrated.

TABLES AND OTHER DATA FOR ENGINEERS AND BUSINESS MEN—Compiled by Charles E. Ferris, B. S., Professor of Mechanical Engineering, University of Tennessee. Knoxville, Tenn.: The Author. Leather: 3 x 6 in.; pp. 230; 50c.

SEWAGE DISPOSAL—By Leonard P. Kinnicutt, Late Director Department of Chemistry, and Professor of Sanitary Chemistry in the Worcester Polytechnic Institute; C. E. A. Winslow, Professor of Public Health in the Yale School of Medicine and Curator of Public Health in the American Museum of Natural History, New York, and R. Winthrop Pratt, Consulting Engineer, M. Am. Soc. C. E. Second Edition, Rewritten. New York: John Wiley and Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 547; illustrated. $4.

THE SHIPBUILDING INDUSTRY—By Roy Willmarth Kelly, Director, Harvard Bureau of Vocational Guidance, Author of "Hiring the Worker," and Frederick J. Allen, Assistant Director, Harvard Bureau of Vocational Guidance, Author of "The Shoe Industry;" with an Introduction by Charles M. Schwab. Boston and New York: Houghton, Mifflin & Co. Cloth; 6 x 9 in.; pp. 303; illustrated. $3.

STATE ENGINEER OF WYOMING: Report for 1917-18—By James B. True, State Engineer, Cheyenne, Wyo.: The Author. Paper; 6 x 9 in.; pp. 256.

Material on surface waters of Wyoming, with gaging records, occupies 154 pages.

STATISTICS OF COMMON CARRIERS: A Preliminary Abstract Dec. 31, 1917—Washington, D. C.: Bureau of Statistics. Paper; 9 x 12 in.; pp. 75.

SUMMARY OF SOLDIER SETTLEMENTS IN ENGLISH-SPEAKING COUNTRIES—Elwood Mead, Consulting Engineer, U. S. Reclamation Service. Washington, D. C.; Department of the Interior. Paper; 6 x 9 in.; pp. 27.

WAR ADMINISTRATION OF THE RAILWAYS IN THE UNITED STATES AND GREAT BRITAIN—By Frank Haigh Dixon, Professor of Economics, Dartmouth College, Chief Statistician, Bureau of Railway Economics, and Julius H. Parmelee, Statistician, Bureau of Railway Economics [Preliminary Economic Studies of the War, Carnegie Endowment for International Peace]. New York: Oxford University Press. Paper; 7 x 10 in.; pp. 155. $1.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Proposes Definition of Engineering

Sir—During some committee work, drafting a proposed registration law for the State of Michigan, it appeared desirable to include a definition of the term "Engineering." The writer submitted the following:

"Engineering is the ingenious application of the principles of science to the economical production and use of materials and energy."

It was suggested that the word "ingenious" was insufficient and that "judicious" should be coupled with it.

Would you like to try this definition on your readers?

E. M. WALKER.

Michigan Central R.R. Station, Detroit, Mich.

Honor American Engineer by Election To L'Institut de France

Sir—In your issue of Jan. 16, 1919, p. 162, there appeared a short notice concerning the election of Dr. J. A. L. Waddell to L'Institut de France in the Académie des Sciences. In view of the fact that he is the first American practicing engineer ever taken into that scientific body, or even into the Institute itself, and that the election was stated by high French authority to be intended as "a new expression of the gratitude which we (the French people) owe to your great nation," it seems to me that the occurrence is worthy of more than a perfunctory or passing notice.

Few Americans recognize that the French Academy of Sciences is the most select body of scientific men in the world, and that admission to its ranks is truly the highest honor to which any scientific man can attain. As proof of this, I repeat the fact stated in your notice that the resident membership is limited to 66 and the corresponding membership to 116. One could compile from its roster a long list of the world's best known scientists who have lived during the past 125 years, such as: Sir David Brewster, the Scotch physicist; Robert W. Bunsen, the chemist who invented the gas burner that bears his name; Sir William Crookes, the famous English physicist; James Dwight Dana, the well known American scientist; Charles R. Darwin and Sir George H. Darwin, father and son, of worldwide fame; Sir Humphry Davy; Sir Michael Faraday; Sir Edward Frankland, the well-known scientist; Asa Gray, the former dean of American botanists; Herman L. F. von Helmholtz, the eminent German physicist; Sir William and Sir John Herschel, father and son, the famous English astronomers; Baron Friedrich H. A. von Humboldt, the explorer; Thomas Henry Huxley, the English physicist and writer; Lord Kelvin (previously Sir William Thomson) the great Irish scientist; Samuel P. Langley, the American aëronautical expert; Pierre S. de Laplace, the prominent French astronomer; Count Ferdinand de Lesseps, the canal builder; David Livingstone, the African explorer; Elie Metchnikoff, the Russian physician; Fridtjof Nansen, the Arctic explorer; Louis Pasteur, the eminent French chemist, and James Watt of steam-engine fame.

I therefore take the liberty of bringing to the notice of your readers the great compliment which has been conferred upon the American nation, the engineering profession of this country, and one of its well known members.

JOHN LUNDIE,
Consulting Engineer.

New York.

These Engineers Also Served

Sir—In this post-bellum period, when War Department and other Government officials are bestowing crosses, honors and "lime wash," and each and every department or branch of the "service" is being boosted for its efficient and marvelous contribution toward the victory, I bespeak your attention and offer a word in behalf of those *engineers who did not wear a uniform*, but who contributed their energy and brains to the common cause.

The results accomplished in the production of camps, cantonments, Army and Navy bases, warehouses, and war industry plants, are in no small measure attributable to the patriotic and untiring efforts and energy of civilian engineers, who have for the past twenty months devoted their time and organizations to the Government's needs.

For a civilian to fit himself into a military organization, where red tape and ancient civil-service methods delayed the machinery, required no small amount of adaptability and an unlimited amount of resourcefulness and diplomacy. The problem was made all the more difficult because of the fact that many of the Government contractual officers were men recently commissioned from civil life, who in turn were equally ignorant of the operation of the newly constructed war machine.

It is to the everlasting credit and renown of the civilian engineers that they met the situation squarely and produced results. From rodmen and draftsmen to supervising and consulting engineers they one and all worked toward a common end, and it is for these, unhonored and unsung, who wear no service stripes or insignia, but who did their bit, I write these lines.

These same men will now be turning their thoughts and energies toward the country's construction and industrial problems, and with the same adaptability, ripened by experience, they will meet the new problems and solve them.

P. H. NORCROSS.

Washington, D. C.

A Fair-Compensation Form of Contract

Sir—Considerable discussion has appeared in the columns of your paper regarding different types of fair-compensation contracts. It may, therefore, be of interest to some of your readers to take note of a type of contract on the basis of which bids were asked recently by the Sebastian bridge district, Fort Smith, Ark., for a reinforced-concrete bridge across the Arkansas River, to cost approximately $550,000.

The bridge district first asked for a lump-sum bid

based on certain quantities with unit prices to be used for additions or reductions in such quantities. As an alternative, the board also asked for a bid as follows: Under item 1 the contractor should name a lump sum to represent the total cost of the work, including fair overhead, administrative charges, freight, transportation of men, labor cost, material cost, etc.; second, an additional sum to cover the contractor's profit and the use of all machinery required for the proper execution of the work.

It was further stipulated that any saving effected in item 1 would be split 50-50 between the contractor and the bridge district. In the event of the cost being in excess of the first item, the second item, or fee, would be penalized for such excess up to an amount equal to two-thirds of such fee.

This gives the contractor every incentive for economical work on a profit-sharing basis; gives the owner every right to assume that a reasonable loss might occur, as against the original estimate, without affecting the cost to him, and also protects the contractor from loss due to unforeseen contingencies, as he can so work out the fee item that he will still receive enough to compensate him for depreciation of outfit and use of money.

This form of proposal was worked up by Hedrick & Hedrick, consulting engineers, of Kansas City, Mo.

N. F. HELMERS,
Siems, Helmers & Schaffner, Contractors.
St. Paul, Minn.

Engineers' and Artisans' Pay

Sir—With further reference to the matter of engineers' salaries in comparison with those of other skilled artisans, the following announcement by the local unit of the bricklayers, masons and plasterers' union, published in a local newspaper, may be of interest:

"On and after Apr. 1, 1919, the scale of wages of this union shall be $1.25 per hour, excepting on all hollow-tile and cement-block work, which shall be at the rate of $2 per hour, excepting partitions, which shall be at the rate of $1.25 per hour. All concrete construction and other artificial masonry shall be under the direct supervision of a member of the B. M. & P. I. U."

Transitmen on municipal work here, competent to act as inspectors, receive $100 per month.

J. H. GILES,
City Engineer.
Pocatello, Idaho.

Hand Hammering of Concrete Forms Not New

Sir—Referring to the editorial in *Engineering News-Record* of Jan. 23, 1919, p. 169, entitled, Hammering Forms a Useful Development in Concrete," I wish to say that while mechanical hammering of forms in order to improve density of concrete may be a new idea with the shipbuilders, the use of hand hammers for that purpose is not new.

In the construction in 1907 of the U. S. Grant Hotel, at San Diego, Cal., then considered the largest reinforced-concrete building in the world, a special "mallet gang" was organized, with orders to keep up a continual hammering against forms while the concrete was being placed; particularly against the form for the exterior of the building, which was all of concrete in elaborate detail. It was only by hammering that we could successfully fill all moldings and eliminate the air bubbles on the wall surfaces which left unsightly holes.

In the construction of the Timken office building in San Diego the next year, we used this same method with particular success in placing concrete for the many office partitions. They were of concrete 2 in. thick, reinforced with ¼-in. steel rods. It was only by continual hammering that we could insure a complete permeation of concrete in the narrow forms.

The writer makes no claim to having introduced this method on these buildings, with which his connection was that of superintendent for the architect. In his own mind he has always given credit for the idea to the organization of Carl Leonardt, contractor for the U. S. Grant Hotel building 12 years ago. CARL REGER.
Morgantown, W. Va.

Shall We Have a Trade Union of Professional Engineers?

Sir—That the wages of engineers have lagged behind those of tradesmen because of lack of organization, as R. N. Atherton sets forth in his letter on p. 201 in your issue of Jan. 23, few will question. But is the remedy one of expediency through a union affiliated with the American Federation of Labor? Is engineering a trade to be classed with the "other trades?" Most engineers consider engineering a profession, and feel that as members of the profession there is no place for them in the ranks of organized labor.

The outstanding characteristic of union labor is selfishness. It tries to get what it wants by threats, intimidation, the application of force, and exhibits its force by strikes. A professional man is one who makes his living by means of education, primarily by the exercise of mental rather than physical effort. In addition, altruism is one of his characteristics. Furnishing a background to the more immediate and personal need of wages is the constructive work that calls for imagination, and, above all, service to the public, to one's fellow men. These are the problems of a profession.

The engineering profession is at the point of choosing the kind of organization it will have for collective effort. The American Institute of Architects, the American Medical Association, the bar, and the Chamber of Commerce are the types engineering organization will parallel. Such is the American Association of Engineers.

It is proper here to say that the efforts of the American Association to raise the pay of the technical engineer in railroad employ have been successful, much beyond our early hopes. New schedules have been put into effect on many roads, and others will follow. An assistant secretary was employed Feb. 1 to devote his time to the railroad field. A conference of railroad men will be held in Chicago Mar. 17 to discuss problems of an economic nature affecting their welfare.

Engineers must do a little housecleaning in order to be a profession, as did the doctors in eliminating the quacks. The answer is licensing. The American

Association of Engineers has been active in licensing and will devote most of the next issue of the *Monad* to this subject. After the housecleaning—after the standards of the profession are raised—we can give attention to the many constructive social problems challenging our best endeavor.

Since your correspondent invites engineers to join the union, it would seem proper that this new business organization of professional engineers should be brought to their attention through your columns. The choosing can be safely left to the individual engineer.

C. E. DRAYER,
Secretary, American Association of Engineers.
Chicago, Ill.

High Authority Restricts the Engineer

Sir—Referring to your editorial "Not Only by Their Works Shall Ye Know Them," in *Engineering News-Record* of Jan. 30, 1919, p. 215: Governor Smith has ample precedent for his disregard of the engineer in the new state reconstruction commission. Read President Wilson's reply to the suggestion of the Engineering Council that an engineer be appointed on any prospective national reconstruction commission: "You may rest assured that I realize what a service engineers can render in reconstruction problems from time to time."

You will note the emphasis of "can" and "from time to time." As permanent members of such a commission they are not to be considered.

St. Marie's, Idaho. M. S. PARKER,
Consulting Engineer.

Using Series of Uniform Loads To Obtain Maximum Stress

Sir—The principle of the diagram for fixing the position of a series of uniform loads to produce maximum stress, described by Mr. Christensen in your issue of Dec. 26, 1918, p. 1193, was discovered and applied by the writer in computing the stresses in a spandrel braced two-hinged arch, while associated with Mr. Christensen in work on the Niagara River Bridge.

A careful check was made of stresses obtained from an equivalent uniform engine load with those from corresponding wheel loads computed with the transparent scale described by Dr. Steinman in *Engineering Record* of Apr. 24, 1915, p. 517. The computation of stresses from wheel loads with Dr. Steinman's scale was found to be extremely tedious when compared with the use of the writer's diagram in connection with Mr. Christensen's equivalent uniform loading. The time required by the former method was fully four times as great since, owing to the curved and irregular shape of the influence lines, no criterion is available for determining the position of the train to produce maximum stress. This must be determined in practically all cases by trial.

A comparison of results obtained from Dr. Steinman's "Chart of Equivalent Uniform Loads" (see *Engineering News* of Apr. 22, 1915, p. 780), with those from Mr. Christensen's loading, for several examples of curved influence lines, varying in length from 230 to 600 ft., indicates that the errors resulting from the use of Dr. Steinman's chart are approximately double the errors resulting from the use of Mr. Christensen's loading. The maximum error found by the former method was approximately 5 per cent., while with the latter method it was about 3 per cent., compared with results from corresponding wheel loads. With either method it is necessary to compute the influence areas accurately and the amount of labor and the chance for mistakes are practically the same.

In designing long-span structures with curved or irregular influence lines, the loading and diagram described by Mr. Christensen may be used with facility equal to that of any other method heretofore employed; the results more closely approximate those determined from wheel loads than with any other method, and the time required is only a small fraction of that required in using wheel loads.

J. H. FLYNN,
Superintendent of Construction, Burroughs Adding Machine Company.
Detroit, Mich.

Camp Sanitation in India

Sir—The article by Harry N. Jenks in your issue of Jan. 23, 1919, on sanitation at the Namtu camp of the Burma Mines, Ltd., is of much interest to me and doubtless to others with experiences in the Far East. For many years in all parts of the Far East under British control, where large or small bodies of coolie labor have been employed, sanitary regulations similar to those described by Mr. Jenks have been rigidly enforced.

Some years ago I had much to do with coolie labor (Malabar or Tamil), and saw these regulations in full operation and was held responsible for their enforcement. Full reports have to be made to the Government authorities, and assessments periodically paid to the "District Medical Aid" for the upkeep of the local hospitals and dispensaries and of the district European doctor (medical officer in charge) and his very capable native or Eurasian local assistants. I can truthfully say that the coolie "lines" or quarters on all construction operations were cleaner than many of the streets of Philadelphia are today.

To most people in the United States, India is a sealed book. Few knew of its teeming millions of industrious workers, skilled in all manner of crafts and arts for many ages. It is an interesting part of the world for an engineer to visit. He will find colossal reminders of magnificent engineering works—full evidence of a very high order of civilization and constructive capacity—in India, Ceylon and Burma.

Mr. Jenks mentiones the native contractors. I have had native masons, Tamils from Madras, and men from Canara and elsewhere, do the best of work. My experience with carpenters, chiefly Singalese, has been equally satisfactory, and the native blacksmiths and machinists of various other races "caught on" very quickly. Common coolie labor usually works on a task system. Everything is done by the job.

Mr. Jenks' article is very interesting. To those who have been in the Far East and have not yet been able to cast off its fascinating spell it is like a memory of old times.

GEORGE HARPER.
New York City.

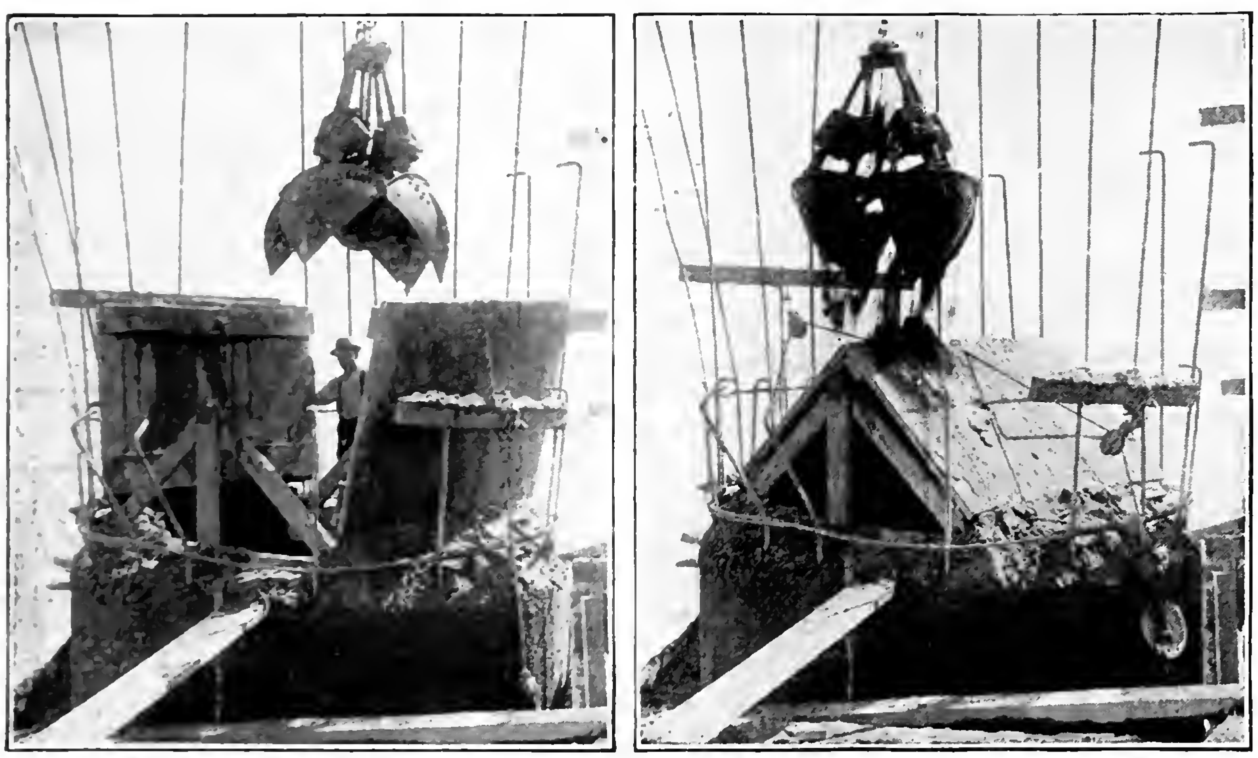
HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Trap Door Aids in Excavation of Cylinder Foundation for High Tower

SPOTTING a clamshell bucket in the comparatively narrow opening of a concrete cylinder foundation is no easy job in the prevailing high winds of the St. Lawrence. As shown in the accompanying view of the tower foundations of the new 4801-ft. transmission line over the St. Lawrence River, recently built by the Shawinigan Water & Power Co. (described on p. 383 of this issue), difficulty was avoided by the construction of a trap door with inclined sides which avoided any movement of the derrick boom.

The device was invented by the foreman of the work, Thomas Burham. Before the trap door was put on, the excavating procedure was, first to spot the derrick boom right over the cylinder, then to lower the bucket, pick up a load, and dump the material by swinging the derrick. On account of the high winds always encountered in the valley, it was found rather difficult for the hoist runner to stop the boom directly over the opening, but by means of the trap door it was possible to keep the boom guyed in the same position during the excavation of one cylinder. All that was necessary was to lower the bucket, pick up the load, close the trap door, and dump the material directly on top of the door. It would then by gravity slide off and deposit itself around the cylinder. The doors were then opened and the procedure was repeated.

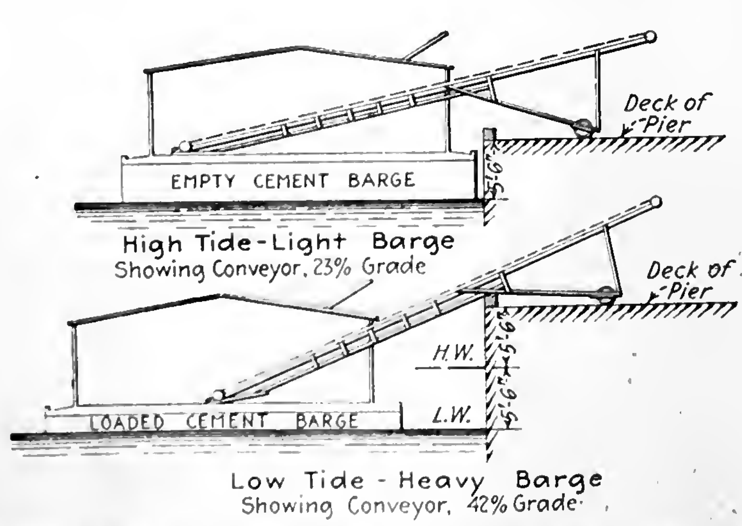


TRAP DOORS ALLOW BUCKET TO DIG IN CYLINDER AND TO DUMP CLEAR

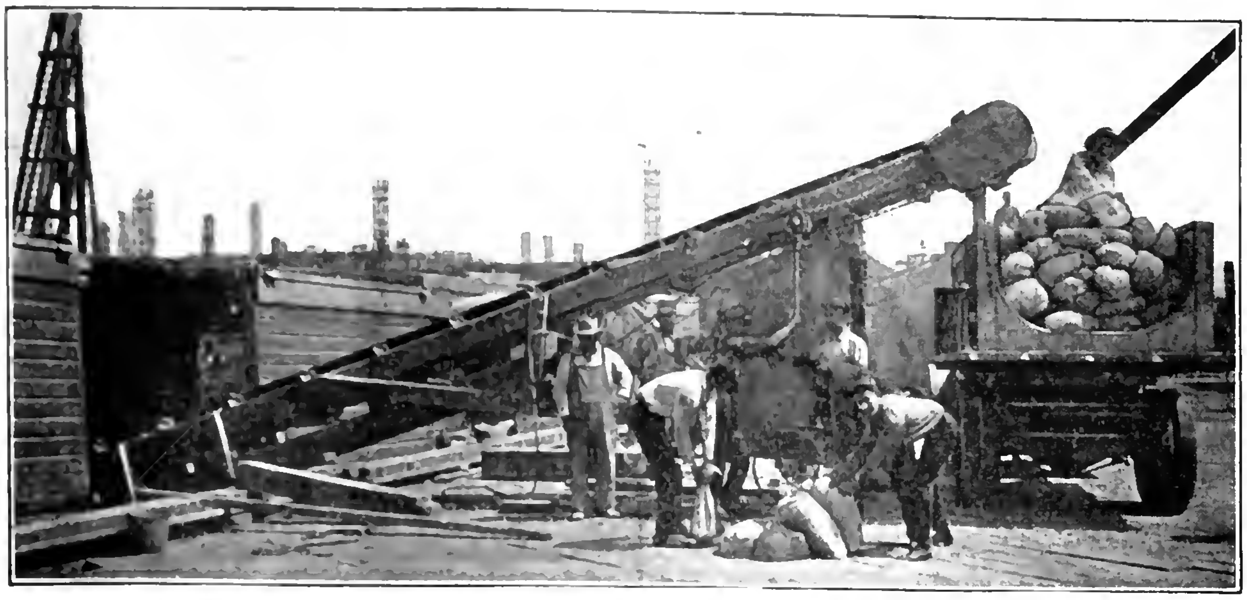
Other Articles in This Issue of Interest to Contractors:

Special Belt Conveyor Saves Time in Unloading Cement Barges

CEMENT was rapidly unloaded from barges at the South Brooklyn Army supply base by means of a specially designed belt conveyor. The special truck body shown in the illustration held about 110 bags, and could be filled in from 8 to 10 min. A battery of six of these machines, which is shown in operation in an article on p. 366 of this issue, was kept busy in the height of the construction season unloading sufficient cement to supply the mixing plants. Being substantially constructed and supported under the engine box with wheels, it could be easily moved from one location to another, according to the places where the boats docked. The length of the device was 45 ft. There were 22 upper rollers, about 6 in. in diameter, 6 return rollers 6 in. in diameter and two end rollers of about 16-in. diameter. The belt which traveled over the rollers was 24 in. wide. A 10-hp. gasoline motor supplied the power. A 15-hp. motor is recommended for this work, so as to increase the speed on steep grades. The truck body shown was originally constructed to haul bulk cement which it was originally intended to use on this job. As this was not found practicable, the trucks were used for bagged cement. The interiors were shaped, made narrower at the forward end and lined with sheet steel, so that when the truck



DEVICE GIVES CLEARANCE AT HIGH AND LOW TIDE



TRUCK BEING LOADED FROM SCOW WITH BELT CONVEYOR

ended up all cement would flow readily from the body.

As stated, this type of body was designed for bulk cement and was used on only a few trucks. Bagged cement dumps readily from ordinary boxes.

Six men were required to throw on the bags at the lower end of the conveyor, while one man arranged the bags on the trucks. When it was necessary to move, these were sufficient to pick up the initial end and wheel the device to the new location. The sketch shows how clearance was obtained at high and low tide and with loaded and empty barges.

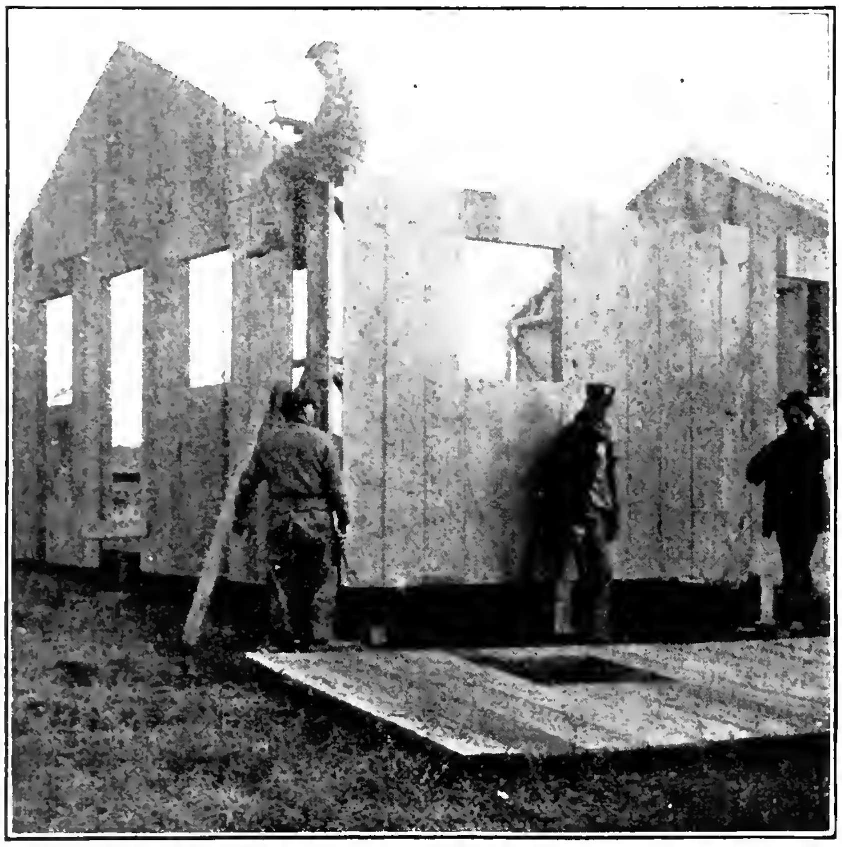
The work was done under the supervision of the Construction Division of the Army. Brig.-Gen. R. C. Marshall, Jr., is chief of the Construction Division, Lieut.-Col. H. F. Crocker is constructing quartermaster, and Maj. George Perrine, Quartermaster Corps, National Army, is directly in charge of this part of the work.

The general contractor is the Turner Construction Co., of New York City, of which A. C. Tozzer is executive manager.

Quantity Production of Officers' Huts By Erection of Framed Units

CONSTRUCTION of 698 huts, 20 x 20 ft., for the extension to Camp Custer, was facilitated by the erection of ends and sides as completely framed units. A sample hut was built, and a duplicate was made of each piece of lumber entering into the building. These duplicates were set aside as patterns and jigs were set up from them, so that all the cutting for the huts was done at a mill centrally located. Platforms, later used as hut floors, were erected and made into templets for framing the four sides. When framed, the hut sides were piled like on like, and tractor-hauled wagons took four sides as a load to the hut site. Foundation gangs built the floor platforms. Then the erection gangs set up sides and ends and placed the roof, all lumber for which had been cut to dimensions at the mill. This operation completed the outside of the building, except doors and windows. Finishing gangs completed the buildings. The Camp Custer extension was constructed by the W. E. Woods Co. contractors, of Detroit, Mich., under the direction of Maj. T. A. Leisen, constructing quartermaster, and Samuel A. Greely, supervising engineer.

SIDES AND ENDS FRAMED ON TEMPLET PLATFORMS



SIDES AND ENDS ERECTED AS FRAMED UNITS

Costs at Los Angeles Municipal Asphalt Plant

During the fiscal year which ended June 30 the municipal asphalt plant at Los Angeles turned out 634,-860 cu.ft. of mixture, according to the annual report of the Engineering Department of the city. This covered nearly all the standard asphaltic surfacings, and the cost per cubic foot ranged from 13.03 to 15.88c., the average being 15.6c. These figures represent an increase in cost over those of 1916-17 of approximately 19%, which is attributed to higher prices of labor and material. The plant was designed and built by the Engineering Department, and the cost, including additions to the original structure and equipment, amounts to $28,625.

NEWS OF THE WEEK

New York, February 20, 1919

Associated Contractors Appoint Acting Secretary

At a meeting of the Executive Committee of the Associated General Contractors of America, held in Washington, Feb. 10, it was decided to engage G. W. Buchholz, recently works manager for Fred T. Ley & Co., Inc., New York City, as acting secretary of the association, with the duties of executive manager. William A. Davis, recently of the War Labor Board, was selected to act as organization manager to assist the secretary.

Would Reimburse Contractors For Their War Losses

Minnesota cities of more than 50,000 population will be authorized to reimburse contractors on municipal work for losses on account of war conditions, if a bill that has been introduced in the legislature becomes law. While general in character, the bill is aimed to make good the losses said to have been incurred by the contractor for the new concrete reservoir for the water department of St. Paul. (See *Engineering News-Record* of Jan. 9, 1919, p. 96.) This contract was awarded for $247,000 about four months before the war. It is said that the company figured on labor at $2.25 per day, but had to pay $4 before the work was finished, and had to meet a corresponding increase in prices for materials. Under the city charter of St. Paul the city could not reimburse the company for such losses. The bill is backed by the city authorities of St. Paul, and has been indorsed by the building trades labor organizations of the city.

Dealers, Not Manufacturers, Lower Cement Prices

In the "Construction News" Section of *Engineering News-Record* of Jan. 30, 1919, p. 51, last column, it was stated that portland cement in New York had been reduced from $4 at dock in cargo lots to $3.45. It was not made clear, however, that this reduction was made by the dealers and not by the manufacturers. The price of cement at the mill remains the same; the reduction is a reduction in profits which the dealer is content to take.

Owners Refuse Government Offer For Cape Cod Canal

Pursuant to recent legislation, the Secretaries of War, Navy and Commerce have met and considered the desirability of the Government purchasing the Cape Cod Canal. As they decided that the purpose was desirable, the next step was for the Secretary of War to negotiate the purchase. Accordingly, after investigation and appraisal, he offered the owners $8,250,000 for the property. This offer was declined, and, still pursuant to the law, the Secretary of War then asked the Attorney General to begin condemnation proceedings.

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Professional and Special Section, United States Employment Service; Thomas T. Read, manager Eastern zone, 16 East 42nd St., New York, and Ward R. Robinson, manager, Central and Western Zone, 63 E. Adams St., Chicago.

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

American Association of Engineers, F. H. Meyers, manager, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

No Federal Public Works Department Bill This Session

According to a note in the Washington papers, Senator Kenyon of Iowa has abandoned hope of getting through this session of Congress his bill providing for an emergency department of public works. In lieu of this bill he has introduced a bill to create a joint Congressional executive commission of six to inquire into existing methods of financing the construction and acquisition of homes within the reach of people with modest means.

John Fritz Medal Awarded to General Goethals

The John Fritz Medal Board of Award Committee, composed of representatives of the four national engineering societies, at its annual meeting on Jan. 17 awarded the John Fritz medal to Maj. Gen. George W. Goethals.

Government Surplus Building Material Small

Inventories of All Army Construction Projects Show Relatively Little That Cannot Be Absorbed

Building material on hand for Government work will probably not become available for private use in any great quantity, nor will its disposal cause much disturbance of the market. The War Department has just made an analysis of the surplus material in the hands of the Construction Division—which has probably 90% of all building material in the department and certainly the greater part of all material held by the Government—and as a result announces that most of the surplus will be absorbed in other Government work. The inventories, as of Dec. 31, are divided into the following main groups: Lumber, plumbing and heating, electrical material and equipment, cement, wallboard, millwork, roofing, screening, etc.; miscellaneous building material, steel, nails, bolts, nuts and washers, building hardware, paints and oils, railroad material, paving material, piling and poles, raw material, fencing, belting, cable, etc.; chain, dynamite, caps, etc.; fuel, hose, harness, etc.; lanterns, flashlights, etc.; rope, and miscellaneous. The total cost to the Government of the above materials is approximately $12,000,000. In addition, there are construction equipment, office equipment, small tools, etc., amounting to approximately $3,500,000.

Large quantities of the material are being consumed inside the War Department, the Construction Division alone having made, since Dec. 31, 800 transfers of materials which were declared surplus at one project or another, transferring them to some project where work was being completed. Approximately $2,000,000 worth of building material has been absorbed in this manner, and the transfers still continue.

The War Department is making no purchases where material can be obtained from some other project. The largest single item in the above summary is lumber, representing approximately one-half the total. A contract for this has been made with the producers, and it will be distributed to the market at market prices.

At each of the 476 Army projects there is a constructing quartermaster, who will make sales of his own surplus under general instructions issued from the director of sales. This means that the majority of this surplus will be absorbed in the particular locality in which it is situated.

Annual Convention of Engineering Institute of Canada

Standardization of engineering parts and the electrification of railways were subjects of technical interest at the annual convention of the Engineering Institute of Canada, held in Ottawa, Feb. 11-13, with an attendance of about 300 members, including several prominent engineers from the United States. The war accomplishments of Canadian engineers and the development of munition work in Canada were outlined by the president, H. H. Vaughan, of Montreal, who stated that the institute was represented overseas by 960 of its members, being 36% of the total.

"Standardization in Engineering" was the subject of a paper by Capt. R. J. Durley, chief of the Division of Gages and Standards, Imperial Munitions Board, who described the work of standardization in engineering parts carried on in England and the United States. He urged international standardization, especially in airplane parts.

A long and interesting discussion on the subject of good roads followed a paper on the subject by Capt. J. Duchastel, who advocated an appropriation of $50,000,000 by the Federal Government to aid the provinces in constructing highways of national importance. Dr. Ira S. Hollis, representing the American Society of Mechanical Engineers, delivered an address in which he expressed the cordiality of the relations between the United States and Canada, and A. D. Flinn, secretary of the Engineering Council, discussed "International Affiliation of Engineers."

The principal feature of the third day's proceedings was the presentation and discussion of papers on the topic of "Railway Electrification," by John Murphy, Ottawa; W. G. Gordon, transportation engineer of the Canadian General Electric Co., Toronto; F. H. Sheppard, director of heavy traction, Pittsburgh, Penn., and Comfort A. Adams, president of the American Institute of Electrical Engineers. This subject was treated comprehensively, presenting the advantages in the adoption of electrical equipment by the railways.

The new officers elected include Lieut. Col. R. W. Leonard, St. Catharines, Ont., president; Walter J. Francis, Montreal, and D. O. Lewis, Victoria, B. C., vice presidents.

Engineer Heads Housing Bureau

L. K. Sherman, of Chicago, has been made director of the Bureau of Industrial Housing and Transportation of the United States Department of Labor, succeeding Otto M. Eidlitz, who has resigned. Mr. Sherman is a sanitary engineer who has been connected with a number of the public works in and around Chicago, notably the Chicago Sanitary district. He has been serving as assistant chief engineer of the housing bureau throughout the war.

Canadian Government States Federal Road Policy

Plan Described at Meeting of Eastern Ontario Good Roads Association—Other Convention Action

Announcement of the Federal road policy of the Canadian Government was made by a representative at the annual meeting of the Eastern Ontario Good Roads Association, held at the Chateau Laurier, Ottawa, Feb. 4 and 5. The national, and even the international, importance attached to this Government statement made it one of the outstanding features of the meeting.

In giving out the information at the annual dinner, the Hon. Dr. J. D. Reid, Federal minister of railways and canals, whose portfolio includes the Department of Highways, stated that of the 250,000 miles of highways in the Dominion of Canada 200,000 miles are third-class roads leading from the farm to the market; 40,000 are second-class roads leading from the larger centers to smaller market centers, while the remaining 10,000 miles are first-class roads connecting the larger centers of population in the provinces.

The Dominion Government, according to Dr. Reid, agrees to pay an amount toward the cost of first-class roads which will be fair and reasonable. No definite statement regarding the amount was made, but it is believed that it will be either 40 or 50% of the total expenditure. The Hon. Gideon Robertson, minister of labor, suggested that in laying out work care should be exercised that the highways be near larger centers of population where unemployment exists.

In discussing the Federal announcement, the Hon. Findlay McDiarmid, minister of public works and highways for the Province of Ontario, stated that it would result in his department designating a greater mileage of provincial highways and would mean more rapid construction. Ontario had passed suitable legislation two years ago. There had been criticism in certain quarters regarding trunk-highway construction under present conditions, and he asked whether the convention favored delay. A negative answer appeared to be unanimous. He said that if ever a progressive program was justified it is now, and it would be the endeavor of his department to build the roads in such a way that they would meet future as well as present demands.

Since its formation in July, 1918, the Good Roads Association has promoted 195 miles of provincial highways, and 331 miles of county provincial highways have been arranged for. This system will connect Ottawa and Prescott, Ottawa and Kingston and Ottawa with the Quebec Highway leading to Montreal.

Nearly 300 delegates were registered during the convention, and the officers elected were as follows: President, Nelson D. Porter, Ottawa; secretary-treasurer, W. Y. Denison, Ottawa.

Highway and Truck Appropriations Agreed to by Conferees

Conferees of the United States Senate and House have agreed upon the Post Office Appropriation Bill, including $200,000,000 for Federal aid to highways and $300,000 to continue experiments with motor-truck transportation of parcels post mail matter. The bill also increases the number of roads to which Federal aid may be applied.

Michigan Plans Extensive Highway Improvements

A bill has been passed by both houses of the Michigan legislature, providing for submitting to the voters, a constitutional amendment which will allow the issue of $50,000,000 in highway improvement bonds. An election for this purpose will be held early in April. Various state farmers' organizations, together with the Grange, have passed resolutions approving of the amendment.

It is proposed to complete a system of about 5000 miles of roads. Roughly speaking, this will comprise two north and south main lines from the southern boundary to Lake Superior, with the necessary cross-connecting lines to reach every county in the state. Arrangements are being made to introduce immediately laws to carry out the plan, if the people approve of the amendment. If present plans materialize the funds will be raised by taxation, each county paying a certain percentage of the cost of the highways within its boundaries, while the remainder will be paid by the state as a whole.

Highway Bond Issue Approved by Minnesota Legislature

Practically unanimous approval of the plan to submit to the people an amendment to the state constitution, providing for a bond issue to construct a definite state highway system, was given recently by both houses of the Minnesota legislature. There were only 10 votes against the plan—three in the Senate and seven in the House—and they were all cast by members of the Nonpartisan League, apparently for political reasons. A complete description of the proposition was given in *Engineering News-Record* of Dec. 26, 1918, p. 1199. The amendment, which provides for the issue of not more than $100,000,000 in bonds, will be submitted to the people at the general election in 1920.

Building Officials Have Meeting

Men responsible for the administration of building laws met at the fifth annual Building Officials' Conference, held at Pittsburgh Feb. 6-8, 1919. A joint session of the conference and the National Brick Manufacturers' Association was held Feb. 7.

The placing of responsibility for safe building construction and a proper compliance with laws and ordinances formed the chief topic of discussion. It was generally agreed that effort should

be made to place that responsibility. The outcome of the discussion was the adoption of the following resolution:

Resolved, that it is the sense of the Building Officials' Conference that for the better protection of the public against unsafe and illegal building construction, suitable legislation should be enacted by which building operations shall be restricted to architects, engineers, builders, superintendents of construction or others who have by proper evidence shown their ability or capacity for undertaking such building operations, and on whom individual responsibility for the safe prosecution of the work and a compliance with the laws relating to buildings can be placed; and

Resolved, further, that the secretary of this organization be directed to furnish, at the request of any member, copies of this resolution for presentation to legislative bodies in support of such legislation.

Rudolph P. Miller, New York, continues as chairman of the conference and F. W. Lumis, superintendent of buildings, Springfield, Mass., is secretary.

Philadelphia Lets Contract for Big Pier

Philadelphia is the first big city actually to let a public works contract of any size. On Feb. 14 the Department of Wharves, Docks and Ferries opened bids for the construction of the Kenilworth St. pier on the Delaware River, a modern freight pier of the well-known Philadelphia type. Eleven contractors made tenders of remarkable closeness, considering the times. On Feb. 17 the contract was awarded to the F. W. Mark Construction Co., of Philadelphia, the low bidder, at $908,000.

The itemized bids are given in the pages of the "Construction News" section. Throwing out two in excess of $1,500,000, the remaining nine bids varied a maximum of $173,000 from the average, with seven bids less than $83,000 above the low bid.

The work comprises 200,000 cu.yd. of dredging, 800 tons of riprap, 30,000 tons of gravel and stone fill and 11,200 sq.yd. of paving.

Contract for Seven Miles of 72-Inch Steel Water Pipe To Be Let

Bids for furnishing and laying 34,590 ft. of 72-in. riveted steel pipe to duplicate the present water-supply conduit between the Boonton reservoir and the Watchung tunnel (near Upper Montclair) are wanted by Jersey City, N. J., until Mar. 25. The work was advertised in 1918, separate bids for furnishing and laying the pipe having been invited, but war conditions prevented letting contracts. Michael I. Fagen is director and Charles A. Van Keuren is chief engineer of the Department of Streets and Improvements, and Clyde Potts, New York City, is consulting engineer for the work.

More Engineers Get High Military Honors

Made Grand Officers of the Legion of Honor and Receive Distinguished Service Medals

High military honors were awarded to several engineer officers in Washington Feb. 13, when General Collardet, the French military attaché, formally presented decorations of the Legion of Honor, previously decreed by President Poincaré, and Secretary of War Baker, in the name of President Wilson, decorated nine American Army officers and two civilians with the Distinguished Service Medal.

Five officers were made Grand Officers of the Legion of Honor, including Maj. Gen. Henry Jervey (previously colonel, Corps of Engineers), Maj. Gen. George W. Goethals and Maj. Gen. William C. Gorgas.

Distinguished Service Medals were formally presented to a number of officers by Secretary Baker. The recipients of the medals included the following:

Brig. Gen. R. C. Marshall, Jr., chief of the Construction Division, for "his zeal, judgment and exceptional administrative ability in the Construction Division of the Army, which enabled serious difficulties to be overcome and the construction necessary for a great army to be provided."

Brig. Gen. Robert I. Rees, chairman of the committee on special training and education, for "his initiative and breadth of vision, to which were largely due the successful measures for training enlisted men for special services and the establishment of the Students' Army Training Corps."

Brig. Gen. William H. Rose, in charge of the Engineer Depot, who "while in charge of the Engineer Depot was charged with the system of purchase of supplies. His exceptional ability, judgment and resourcefulness are apparent in the efficient solution of the many difficult problems involved and in the success attained in supplying the vast quantities of engineering supplies to the Army overseas."

Distinguished Service Medals were also conferred on Guy E. Tripp, "who, as chief of the Production Division of the Ordnance Department, and later as assistant chief of ordnance, displayed fine technical ability and broad judgment in systematizing methods and practices, resulting in the efficient cooperation of industries producing articles of ordnance for the Army," and Edward R. Stettinius, "who, as Director General of Purchases for the War Department, Second Assistant Secretary of war and special representative in France of the Secretary of War, in connection with the procurement of munitions for the American Expeditionary Forces, rendered conspicuous services. His broad vision and splendid judgment have been of the greatest value to the success of the military program."

St. Louis Garbage Will Be Fed To Hogs for a Year

The garbage of St. Louis will be fed to hogs during the year beginning Feb. 15, 1919. Meanwhile, the Board of Public Service will prepare specifications, on broad lines, under which bids for disposal will be invited. During the present year the garbage from the outlying districts will be sold by the city to a number of hog raisers in St. Louis County, the city delivering the garbage at various stations within the city limits and the hog raisers agreeing to pay 25c. a ton for stated amounts. All the remaining garbage collected by the city will be bought by Guy Caron, Little Rock, Ark., for 25c. a ton, and will be delivered by the city to a hog-feeding farm to be established by the contractor within 50 miles of St. Louis. The city agrees to deliver a minimum of 150 tons in three days, and Mr. Caron agrees to take any amount in excess of the minimum. It is estimated that during the summer season the deliveries will be as high as 100 tons per day.

Transportation from the city to the Caron farm will cost the city from 25c. to 40c. a ton, according to the location finally chosen. Thus, for one-half to one-third of its garbage the city will get 25c. a ton, delivered, while for the remainder disposal will cost it from nothing to 15c. a ton. It is estimated that under the worst contingencies the average net cost of disposal for the year will be 5c. to 10c. a ton, which under favorable conditions there may be a small revenue to the city.

Until recently the city paid the Indiana Reduction Co. 87c. a ton for disposal by reduction, the contractor transporting the garbage, at its own cost, from loading docks in the city to its plant. This contract expired Sept. 1, 1918. The company then took the garbage without cost, the city towing it to the reduction works at an estimated cost to it of 20c. a ton. Under an option, the company cancelled this contract, the cancellation to take effect Feb. 15, 1919. All of the foregoing figures are exclusive of the cost of collection.

Portland Grain Elevator Settles During Construction

Settlement of the municipal grain elevator being built at Portland, Ore., has halted work on the structure while studies of the foundation conditions are being made. The building is of concrete, 155 x 111 ft. in plan and 85 ft. high. It is founded on a heavy concrete mat resting in turn on wooden piles 50 to 60 ft. long. It is estimated that these piles are now taking about 60% of their ultimate load. They were designed for a safe load of 25 tons per pile, and some of the piles were loaded with 40 tons without settlement. So far the observed settlement has been about 12 in. and is decreasing. It is not quite uniform, the floor being 4 in. out of level.

Proposes Extensive New York Port Scheme

Before the New York-New Jersey Port and Harbor Development Commission, Feb. 13, Gustav Lindenthal, New York consulting engineer, explained an extensive scheme for the development of the terminal and transportation facilities of the Port of New York which he proposes. The plan calls for a belt railroad in New Jersey tying together the railroads there and connecting with Staten Island, Long Island and Manhattan Island by bridges and tunnels. There would be a classification yard in the New Jersey meadows accessible to all railroads and to motor trucks, from which local freight to Jersey City and Manhattan could be distributed; a multiple-track, high-level bridge across the North River, an elevated railroad connecting with the bridge and paralleling the river water front in Manhattan, with freight and passenger stations and market halls distributed along its length. There would also be tunnels under the river near Battery Place, which would provide circulatory movement of trains to and from the New Jersey side. Further developments would be a tunnel under New York harbor, connecting the present Greenville yard of the Pennsylvania and the Bay Ridge yard of the Long Island, a union station in Manhattan Island for all of the railroads coming through New Jersey, connection via moving platform in a tunnel between all of the north and south rapid-transit lines and the belt-line railroad, and a tunnel connection between the river tracks of the New York Central and the tracks of the other divisions of the same railroad.

The plan proposed is but one of many which have been presented to the commission. It contains features similar to those proposed by William J. Wilgus and by Ernest P. Goodrich some years ago. The estimated cost of the project, not including river-front improvements and shipping piers, would be about $211,000,000.

Money for the California Land Settlement Board

For an extension of the work of the California Land Settlement Board, described at length in *Engineering News-Record* of Dec. 5, 1918, p. 1014, an appropriation of $1,000,000 from current revenue and a bond issue of $10,000,000, available two years hence, are proposed. It is expected that bills to those ends now before the legislature will be enacted. Dr. Elwood Mead, Berkeley, Cal., is chairman of the board.

Bills Call for Power Surveys

Requests for two appropriations for special investigations and report on the power supply have been made by Secretary of the Interior Lane. One of these asks an appropriation of $50,000 for a survey of the power resources all over the United States. This proposed appropriation is embodied in the Sundry Civil Bill. If approved, the work would be done by the Geological Survey. The other request is for an appropriation of $200,000 for a report on the power supply for the industrial region of the northern Atlantic seaboard, extending in general from Boston to Washington. If approved, this work would be done by the Geological Survey and the Bureau of Mines in coöperation. The request for the $200,000 appropriation has been approved by the Secretary of the Treasury and has been forwarded to Swagar Sherley, chairman of the House Committee on Appropriations.

Minnesota Engineers Meet In Joint Sessions

The annual meeting and banquet of the affiliated societies of the Minnesota Joint Engineering Board was held in St. Paul, Feb. 13. It was attended by over 200 representative members of the eight societies affiliated under the board. The speakers of the evening were Edward A. Filene of Boston, director of the Chamber of Commerce of the United States and member of the League to Enforce Peace committee, now touring the country with Ex-President Taft; L. C. Fritch, vice president and chief engineer of the Chicago, Rock Island & Pacific Ry., who spoke on the railway problem; Oscar Hallam, associate justice of the Supreme Court of Minnesota, who delivered an address on "The American Engineer"; W. L. Darling, director of the American Society of Civil Engineers, who spoke on the work of the Development Committee and the engineer's relation to public affairs, and Dwight E. Woodbridge, consulting mining engineer of Duluth.

Before the banquet a business meeting of the board was held at which two delegates from each of the affiliated societies were present and discussed various organization schemes which had been presented by the Engineers' Society of St. Paul, the Engineers' Club of Duluth, the Engineers' Club of Minneapolis and the Minnesota Section of the American Institute of Electrical Engineers.

There was a surprising unanimity of opinion that the Joint Board should continue as a joint board along the lines on which it had already been organized, with the exception that the membership of each society should be increased to three. As the board is organized at present, there is one member from each society, and the work of the board has increased to such a point that each member is carrying too much load. With 24 members, the work can be divided and much more effective service rendered. This body voted to make this change in the organization, and it was concurred in by the Joint Board in business session; this change in its constitution will be immediately presented to the various societies for confirmation.

Isolation Is Problem of North Dakota Engineers' Society

Although no bond issue for good roads is in sight in North Dakota, that state in 1918 put under construction more mileage bearing Federal aid than did neighboring states, according to J. E. Kaulfiss, assistant state highway engineer, who addressed the North Dakota Society of Engineers at the recent meeting held at Valley City. He stated that outside of towns and cities all road improvements consist of grading, shaping, weed extermination and bridge and culvert construction, which will be useful when surfacing becomes financially possible. County work, previous to the establishment of the State Highway Department in 1917, was carried out on the basis of $900 per mile, but already, by common consent and request of counties, the state has increased this to $1500. Of the 350 miles put under construction last season, one-half is complete. Funds and plans will be available for at least an equal mileage this year.

The surfacing of roads has not yet received any serious consideration, but Mr. Kaulfiss was of the opinion the demand would come sooner than most people expected, because of the fact that the state heads the list of persons per automobile, 9.3, with Nebraska next at 9.5. With another bumper wheat crop and unprecedented high prices, the farmers' demands will inevitably be in the direction of good roads all the year round.

In the address of the president, E. J. Thomas, professional difficulties due to isolation and the impracticability of having any but annual meeting activities were emphasized. Authorization was given for a committee to work out if possible some coöperative scheme with the American Association of Engineers whereby service might be rendered throughout the year. Prof. R. H. Slocum, who made the proposal, was of the opinion that a mutually beneficial arrangement could be effected. "Publicity for the Engineer and How to Get It" was the subject of an illustrated talk by W. W. DeBerard, who held that too few engineers utilized the opportunities for publicity of the work of the profession. Licensing of engineers and surveyors was discussed, and the question of standardized fees received attention, but no action was taken.

The officers elected for the coming year are J. A. Jardine, president; Miss E. M. Jack, city engineer, Williston, and R. M. Stee, vice-presidents; W. H. Robinson, state engineer, librarian; Prof. E. F. Chandler, University, secretary. Fargo won the contest for the meeting place next year.

Flood-Control Survey of the River Colorado Proposed

A survey of the Colorado River with a view to flood control is provided for by a bill now before Congress. The bill directs the Secretary of War to

make "a preliminary examination" of the river "with a view to the control of its floods in accordance with the provisions of an act to provide for the control of the floods of the Mississippi River and of the Sacramento River in California," approved Mar. 1, 1917.

Oregon Engineers Discuss Legislation

At the annual meeting of the Oregon Society of Engineers held in Portland on Feb. 3, a spirited discussion of the bill for registering professional engineers, now before the legislature of Oregon, was participated in by nearly everyone present. When a vote was called for, however, the majority was not willing to express a definite opinion for or against such legislation.

A bill abolishing the offices of county surveyor and roadmaster, and creating the office of county engineer in place of them, was indorsed by the society.

The election of officers resulted as follows:

President, John W. Cunningham, of Baar & Cunningham, consulting engineers; third vice president, to serve three years, O. Laurgaard, city engineer of Portland; treasurer, Henry M. Morse, consulting engineer; secretary, Orrin E. Stanley, sewer engineer, Department of Public Works, Portland; directors, to serve three years, Philip H. Dater, district engineer, United States Forest Service, Portland; O. A. Kratz, chief of the Bureau of Construction, City of Portland, and Herbert Nunn, state highway engineer, Salem.

Chief Engineer of Expeditionary Forces Gets Medal

Maj. Gen. William C. Langfitt, chief engineer of the American Expeditionary Forces, received the Distinguished Service Medal from General Pershing on Jan. 18 at headquarters, Services of Supply, at Tours. The decoration was conferred personally by General Pershing, the award being made for efficient conduct of the engineer department's work.

Notes from the Field

In the agitation for higher compensation levels there is danger that many will draw the conclusion that they will get higher pay when the levels go up, despite the quality of their services. Such a conclusion would be unsound. The higher the salary, the stricter the scrutiny in employing and retaining men. Moreover, there will always be the lower grades, no matter how high the general level may be raised. The rewards will go to the good draftsman, the good inspector, the good assistant engineer. The man who is just scraping through, giving an indifferent service, is going to remain in the lower ranks, while his more competent, reliable and conscientious brethren will get the increased compensation.

Take a case recently under observation. An engineer had been advanced in a year's time from the $3000 to the $4300 salary class, though for 10 years his salary had hovered around the $3000 mark. It was conceded that the cost of living and change of work warranted the increase. As a $3000 man no fault was found with his services. He had exercised relatively little initiative; the man above made the decisions.

In the $4300 class his work was subject to much more severe scrutiny. He had reached the class where initiative is demanded. He was expected "to come through big," and he failed.

It was not the employer's hope that he could get the assigned work done for less than $4300, but he knew that he could get mighty good men for $4000, and his duty to himself and his company demanded that he buy the best brains obtainable for the money available.

What applied in this case applies generally. No matter how the general compensation levels may rise, only those will rise with them who have corresponding capacity. The lower grades will always remain, as they do in medicine and the law. They will be filled by those less well prepared, less careful, less faithful.

Only those will rejoice in the coming day who are prepared to earn the higher compensation.

The incident related above suggests also that while it is easy to get a job, the hard part is to hold it. E. J. M.

Council Urges Engineers for Reconstruction Committees

The chairman of the Engineering Council, J. Parke Channing, has sent to Governor Smith of New York and to all other Governors letters in which, after reviewing the serious situation in which many technical engineers now find themselves because of the cessation of work by private enterprise in engineering construction, says:

"Even if it is wise to defer actual construction till prices are more favorable, there is a wonderful opportunity now to make plans for the future." The letter urges the appointment at once of a reconstruction committee, a proper proportion of whose members shall be engineers of prominence, or, if such a committee has already been appointed, that carefully selected engineers be added to its membership, and continues:

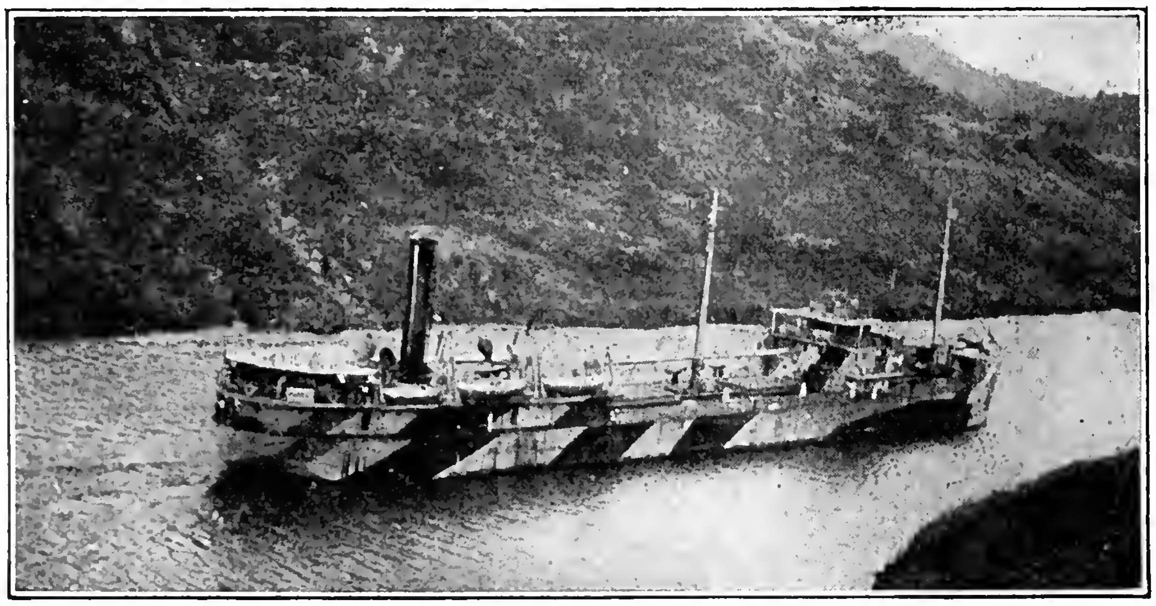
"Highways, schoolhouses and other public buildings, water-works, sewerage systems and public utilities are among the public works which may be planned according to the needs of the state and its communities. Engineers are especially fitted to advise on projects of these kinds. It is suggested that even if at the present time lowest prices for materials and minimum wages may not yet prevail, it will in the long run be an economy to the state to utilize now the professional talent and labor available in making plans for the future, and in executing work which may be urgent."

Record Number of Students

As a result of the war, the Massachusetts Institute of Technology has more regular students than it ever had before at this time of year. The precise number is 1944—this in spite of the fact that practically the whole of the senior class has already been graduated by reason of special courses.

Two Noted Engineering Achievements

The concrete freighter "Faith" passing through the Culebra Cut of the Panama Canal on its way north last fall. The photograph has been withheld until now by the censor.



General Black Heads Federal Port Commission

Maj. Gen. William M. Black, chief of engineers, United States Army, has been made chairman of the Port and Harbor Facilities Commission of the United States Shipping Board, succeeding Edward F. Carry of Chicago, who recently resigned. General Black will continue to perform his military duties in addition to those devolving upon him in his new position. The Port and Harbor Facilities Commission is engaged in the study of the ports of the United States with a view to recommendations as to methods which will increase the use and economy of such ports. It has been in existence for six months or more, but has not as yet presented any public report.

Hydraulic Turbine Casing Breaks and Floods Power Plant

On Feb. 17 the cast-iron scroll case in the upper section of one of the hydraulic turbines in the Wachusett dam power station at Clinton, Mass., broke suddenly, leaving an opening about 12 ft. square. Before the flow could be shut off the escaping water had flooded the power station 4 ft. deep and pretty thoroughly destroyed the movable contents. The generating units themselves were not seriously damaged and require little except drying to put them in service. The total damage is estimated at $5000.

The break was caused by the sudden closing of a wicket gate, presumably by a governor. The flood prevented the operation of the hydraulic gate, and a watchman had to go to the top of the dam and shut off the flow by operating the hand gates in the upper chamber. This took about a half hour. Fortunately, all switches were pulled before the men left the power house, so the only damage was by the water.

The dam is a part of the Metropolitan Water Supply for Boston and the surrounding district.

Engineering Societies

Calendar

Annual Meetings

AMERICAN ROAD BUILDERS' ASSOCIATION; 150 Nassau St., New York City; Feb. 25-28, New York City.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

The Minnesota Surveyors and Engineers' Society gave a prominent place to a discussion of matters of legislation, at the annual meeting held at St. Paul Feb. 12-14. It was pointed out that resolutions passed by the society during the state legislature assembly had had apparently little effect, indicating personal effort with legislators by engineers as being the best means of bringing action in matters of interest to the engineering profession. Among the reports of committees were those on drainage, highways, and municipal engineering. The following officers were elected for the year: President, Harvey S. Dartt, city engineer, Mankato; vice-president, R. W. Acton, engineer of roads, St. Louis County, Duluth; secretary, C. H. Stewart, Department of Public Works, St. Paul, and treasurer, William C. Fraser, municipal engineer, St. Paul.

The Canadian Engineering Standards Association has been incorporated, with headquarters at Montreal, for the purpose of coördinating efforts of producers and users in the improvement and standardization of engineering materials, and promoting the general adoption of standards in connection with engineering structures. The incorporators are Sir John Kennedy, consulting engineer; Dr. Robert F. Ruttan, professor of chemistry; Dr. John B. Porter, professor of mining engineering; Richard J. Durley, engineer, and Henry H. Vaughan, engineer, all of Montreal.

The Vermont Society of Engineers will hold its annual meeting at Burlington, Mar. 12.

The Iowa Engineering Society was addressed by Edmund T. Perkins, president of the National Drainage Congress, on "Government Land Reclamation," at the 31st annual meeting held at Muscatine, Feb. 19-20. Clifford Older, chief highway engineer, Division of Highways, Illinois, read a paper entitled "The Story of the Illinois $60,000,000 Bond Issue Campaign." The afternoon of the first day of the meeting was devoted to the sessions of the sections on drainage engineering, highway engineering and municipal engineering. The subject of standard fees was discussed.

The Dallas Chapter of the American Association of Engineers elected the following officers at the recent annual meeting: President, A. A. Matthews; vice-presidents, Hart Vance and A. P. Denton; secretary, S. J. Treadway.

The Rochester Engineering Society was addressed Feb. 10 by Lieut. Roger D. DeWolf, U. S. N. R. F., U. S. S. "Nevada," who spoke on "Experiences with the Grand Fleet." At the meeting Feb. 14 William H. Earle, assistant superintendent of gas manufacture, Rochester Railway & Light Co., spoke on "Modern Methods of Gas Manufacture."

The Montana Institute of Municipal Engineers held its annual meeting at Helena, Jan. 20-22. Reconstruction problems constituted the general topic. The following officers were elected for the coming year: President, John D. McLeod, Helena; vice-president, Willis H. Ellis, Butte; director, Carl C. Widener, Bozeman; secretary-treasurer, Arthur E. Lamb, Helena. The annual meeting of the society for 1920 will be held in Butte.

The Yakima (Wash.) Engineers' Club elected the following officers at the recent annual meeting: President, T. A. Noble; vice-president, J. O. Greenway; secretary-treasurer, A. L. Strong.

The Engineers' Club of Trenton held a meeting Feb. 13 which was addressed by William H. Burr, who spoke on "Important Features in the Development of Concrete Work."

The Engineers' Club of Philadelphia will conduct an excursion to the Ordnance Proving Grounds, Aberdeen, Md., Feb. 20, for the purpose of inspecting various pieces of ordnance used in the war. Dr. Edward Chiera, University of Pennsylvania, will speak on "The Problem of the Adriatic," at the weekly luncheon of the club on Feb. 25.

The Engineers' Club of Boston elected the following officers at the annual meeting held Feb. 10: President, Charles T. Main; vice-presidents, Charles L. Edgar and Charles L. Gagnebin; secretary, L. S. Cowles; treasurer, Frederic H. Fay.

The Montreal Branch of the Engineering Institute of Canada held a meeting Feb. 20, at which J. L. Busfield spoke on "The Construction of the Canadian Northern Railway Tunnel at Montreal." At the meeting Feb. 27 R. M. Wilson will speak on "The Effect of Ice on Hydro-Electric Plants."

The Louisiana Engineering Society was addressed by Maj. A. M. Shaw on "The Construction Division of the Army," at the meeting held Feb. 10.

Personal Notes

George J. Ray, chief engineer of the Delaware, Lackawanna & Western R.R., is now acting as engineering assistant to A. H. Smith, regional director of railways under the United States Railway Administration, with headquarters in New York City. L. L. Tallyn, division engineer at Scranton, is acting as chief engineer during Mr. Ray's absence.

Maj. B. J. Lambert, Engineers, U. S. A., has received his discharge from the service and has returned to the professorship of structural engineering at the State University of

Iowa. He was commanding officer of the 3rd Battalion, 23rd Engineers (Highway) from December, 1917, to September, 1918, after which he served as bridge engineer for the First Army.

COL. JAMES P. JERVEY, Engineers, U. S. A., who recently returned from active service with the 79th Division, has been appointed United States engineer at Wilmington, Del.

DAVID A. HARTWELL, recently engaged on work at Newport News, Va., for the United States Housing Corporation and the Emergency Fleet Corporation, has been appointed commissioner of public works and city engineer of Fitchburg, Mass., Mr. Hartwell previously served the city as assistant city engineer for three years; for twenty years as city engineer, and for seven years as chief engineer and superintendent of the sewage disposal division.

MAJ. H. AUSTILL, 20th Engineers, who recently returned to this country, has received his discharge from the service and has returned to his former position as bridge engineer, Mobile & Ohio R.R., at Mobile, Ala.

LIEUT. L. C. DODGE, Engineers, U. S. A., Office of Director General of Military Railways, Washington, D. C., has been discharged from the service and entered the bridge department of the Baltimore & Ohio R.R., with headquarters at Cincinnati.

EDWARD S. WALSH, Brooklyn, N. Y., has been appointed deputy superintendent of public works of New York State under Lewis Nixon, who was appointed superintendent of public works, as mentioned in *Engineering News-Record* of Jan. 16, p. 166.

COL. C. H. MITCHELL, Intelligence Department, British Army, has been appointed dean of the faculty of applied science and engineering, University of Toronto, succeeding W. H. Ellis, resigned.

CAPT. E. L. STAPLETON, Gas Defense Division, Chemical Warfare Service, United States Army, has received his discharge and has become associated with Willard C. Brinton, consulting engineer, New York City.

CHARLES E. KIMBALL, who for a number of years served as manager of the machinery department, Harris Bros., Chicago, has been appointed to a similar position with the American House Wrecking Co., Chicago.

GEORGE L. NASON, Engineers, U. S. A., has received his discharge from the service and has returned to his office in the Endicott Building, St. Paul, Minn., to resume the practice of landscape architecture and engineering.

CAPT. STEUART PURCELL, Quartermaster Department, U. S. A., has been appointed division engineer in charge of highways under G. F. Weighardt, city highways engineer of Baltimore.

CHARLES W. WHITTLE has been appointed assistant engineer, alley and footway division, highway engineer's department, of Baltimore.

J. L. CUMMINGS, acting bridge engineer, Mobile & Ohio R.R., Mobile, Ala., has been appointed division engineer of the Mobile division, with headquarters at Meridian, Miss.

S. W. CHILES, contracting engineer, Bethlehem, Penn., has gone to Santo Domingo to become resident engineer of construction work under A. J. Collett, director general of public works under the United States Military Government.

EDWARD A. LAMBERT, recently construction engineer for the Procter & Gamble Co., Cincinnati, has joined the staff of Fletcher-Thompson, Inc., industrial engineers, Bridgeport, Conn.

LIEUT. WALTER L. LEWIS, 136th Artillery, who recently returned from France, has received his discharge from the service and has resumed his work in the engineering department of the Great Northern Railway.

W. C. FAWCETT and KARL L. ROTHERMUND, Wheeling, W. Va., have become associated under the firm name of Fawcett & Rothermund, consulting engineers.

S. F. RYAN has been appointed division engineer, St. Louis division, Mobile & Ohio R.R., with headquarters at Murphysboro, Ill.

EARLE J. HEWIT, formerly with the Illinois State Highway Department, has become assistant engineer in the Department of Highways, State of Tennessee.

A. F. BROWNLEY has been appointed assistant engineer, sewerage division, highway engineer's department of Baltimore.

OBITUARY

LIEUT. COL. HIRAM J. SLIFER, 21st Engineers (Light Railway), died in France Feb. 3. He was born in 1857 and was a graduate of the Polytechnic College of Pennsylvania. He had been engaged in railroad work since 1880, when he became assistant engineer in the construction of the Mexican National Ry., and was later engaged in construction and maintenance work with the Pennsylvania R.R. and the Chicago & Northwestern Ry. as division engineer until 1898, when he became division superintendent for the Chicago & Northwestern, and afterward general superintendent, Central division, Chicago, Rock Island & Pacific Ry. From 1905 to 1907 he was engaged in special work as steam-railway expert for the J. G. White Co., of New York. In 1907 he went to Panama as assistant to the president of the Panama R.R., remaining there until he joined the Chicago Great Western as general manager in 1909, resigning two years later to engage in private practice.

MAJ. C. S. NOBLE, veteran of the Spanish-American War, and lately with the Y. M. C. A., died recently in Tours, France. For a number of years he was engineer for Oregon City, Ore., later becoming associated with the State Highway Commission. He resigned from the highway commission to go to France last autumn.

OSCAR MOORE LANCE, who for 23 years was general manager, Spring Brook Water Supply Co., Wilkes-Barre, Penn., died recently at Kingston, Penn. He was graduated from Lehigh University in 1872, and was for many years superintendent of the three public utility companies of Plymouth, Penn. He became general manager of the Spring Brook Water Supply Co. in 1896, at the time of its formation.

DANIEL B. BANKS, consulting engineer, Baltimore, who had charge of the planning and construction of the high-pressure fire-service system of that city, died Feb. 7. He was born in 1864 and received his education at Princeton University. His first engineering experience was as a rodman on the Shenandoah Valley R.R. and with the Baltimore & Ohio R.R. In recent years he specialized in water-supply work.

E. H. JACOBS, construction engineer and superintendent of distribution lines, Western States Gas & Electric Co., Stockton, Cal., died in that city recently. He went to Stockton seven years ago to undertake the laying of the new underground conduit system, having previously been engaged in work in San Diego under H. M. Byllesby & Co., with whom he had been associated in Chicago.

LUTHER P. FRIESTEDT, president of L. P. Friestedt Co., contractors, Chicago, and of the Friestedt Underpinning Co., New York, died at Los Angeles Feb. 5, at the age of 59. He was engaged in the construction business during all of his working life. He was the inventor of the form of steel sheet-piling known by his name.

Material-Handling Machinery Association

Manufacturers Form Organization — Port and Terminal Problems to Receive Particular Attention

Notices have appeared in this journal of the steps being taken to form an association of manufacturers of material-handling machinery. The preliminary organization work has now been completed, a committee on membership is engaged in recruiting the charter membership, a secretary-manager has been selected and has entered upon his duties, and a preliminary plan has been outlined for the work of the association.

Result of War Taught Lessons

The impetus to form the Material-Handling Machinery Manufacturers' Association, the name of the new body, came in part from the lesson which the war taught as to the benefits to the country and to the manufacturers from mobilization in a strong trade association, and in part from suggestions made, by the Department of Commerce and the Shipping Board. These two Government agencies, realizing the need for more efficient operation of railway terminals and ports, urged the manufacturers to get together in order that they might the more efficiently attack these difficult problems, and that the Government in its studies might have available in get-at-able form the combined talent of the handling-machinery industry.

In general, the lines of work—technical, educational, promotional, etc.—will parallel those of other trade associations, but the nature of the problems will require more extensive technical committee work than is customary in such bodies. In one particular the proposed work presents an unusual phase. Since material-handling problems are found in every industry, relations will be cultivated with existing trade associations. These organizations will be asked to appoint committees on material handling which will meet with corresponding committees of the Material-Handling Machinery Manufacturers' Association. Thus the material-handling problems of the various industries will come before broadly representative committees of material-handling experts. Already several of these coöperating committees have been arranged for.

Officers and Members

The active conduct of the association's work will be in the hands, as secretary and manager, of Zenas W. Carter, formerly commissioner of the Associated Metal Lath Manufacturers, and previously field secretary of the Granite Paving Block Manufacturers' Association. The officers of the association are: President, Calvin Tomkins, formerly commissioner of docks, New York City; vice-president, J. A. Shepard; treasurer, Lucian C. Brown; directors, Mr. Shepard, Mr. Brown, R. W. Scott, F. W. Hall, William Clark, J. C. Walter, C. M. Watson and Fred Stadelman. Four additional directors are to be chosen when the charter membership is completed.

The following companies have come together in the work of forming the organization and are now constituting themselves a membership committee to complete the charter membership of the association:

The Watson Elevator Co., Edward F. Terry Mfg. Co., the International Conveyor Corporation, Rownson, Drew & Clydesdale, Inc., New Jersey Foundry & Machine Co., Hayward Co., Elwell-Parker Electric Co., Sprague Electric Works, Otis Elevator Co., Manning, Maxwell & Moore, Inc.; Robins Conveying Belt Co., Michener Stowage Co., New York City; Shepard Electric Crane & Hoist Co., Montour Falls, N. Y.; Brown Portable Conveying Machinery Co., Chicago, Ill.; Karry-Lode Industrial Truck Co., Long Island City, N. Y.; Whiting Foundry Equipment Co., Harvey, Ill.; Wellman-Seaver-Morgan Co., Cleveland, Ohio; Alliance Machine Co., Alliance, Ohio; Alfred Box & Co., Inc., Philadelphia, Penn.; Meade-Morrson Mfg. Co., East Boston, Mass.; Alvey-Ferguson Co., Cincinnati, Ohio; Heyl & Patterson, Inc., Pittsburgh, Penn.; American Hoist & Derrick Co., St. Paul, Minn.; Cleveland Crane & Engineering Co., Wickliffe, Ohio; Clyde Iron Works, Duluth, Minn.; Ohio Locomotive Crane Co., Bucyrus, Ohio; Northern Engineering Co., Detroit, Mich.; Electric Controller & Mfg. Co., Cleveland, Ohio.

Offices have been opened at 35 West 39th St., New York City.

Head of War Labor Policies Board Resigns

The chairman of the War Labor Policies Board, Felix Frankfurter, has tendered his resignation to the Secretary of Labor. The board will go out of existence in a few weeks, its activities having come to an end with the close of the war. The executive officer of the board, George L. Bell, will go to New York to become the impartial chairman of a permanent board of arbitration to be organized to handle labor disputes. Mr. Frankfurter was formerly a professor in the Harvard Law School. He has not announced his future plans.

American and Italian Engineers to Promote Public Works

An association has recently been formed known as the "Societa Itala-Americana di Studi i Lavori Publici," in which American engineers and business men are joining with Italian engineers and bankers to study and promote public works in Italy. The society was incorporated in Rome by interests representing the American International Corporation of New York and the Banca Italiana di Sconto of Italy.

The president is Senator Guglielmo Marconi, the inventor of the wireless telegraph, and the directors are the Marquis de Solari, Sig. Angelo Pogliani (managing director of the Banca di Sconto) Maj. James F. Case, H. Nelson Gay and F. Lavis.

The objects of the new company are the study of opportunities for the coöperation of American and Italian interests in the promotion of trade, and the prosecution of public works and other projects of an engineering and construction nature. The movement represents a step toward a better understanding and coöperation between the two countries.

Business Notes

The Victor L. Phillips Co., of Kansas City, has taken over the complete line of "Rex" mixers and pavers for the eastern half of Missouri and also the entire states of Kansas and Oklahoma.

Westinghouse Church Kerr & Co., engineers and constructors, 37 Wall St., New York, announce that they have opened an office in the Western Indemnity Bldg., Dallas, Tex., in charge of A. W. Nichols.

The Epping-Carpenter Pump Co., of Pittsburgh, Penn., announces that Theodore R. Hermanson, formerly with the Harrison works of the Worthington Machinery Corporation, has been appointed works manager.

Trade Publications

The Oshkosh Mfg. Co. of Oshkosh, Wis., announces that its 1919 catalogue of contractors' equipment is ready for distribution.

The Independent Pneumatic Tool Co., of Chicago, Ill., has issued a folder describing the Thor Universal Electric Drill. Specifications and illustrations are given for nine different types of machine.

The Lakewood Engineering Co., of Cleveland, Ohio, has issued bulletin No. 25, entitled "Flat-Wheel Haulage Systems." It is an $8\frac{1}{2}$ x 11-in. 23-p. pamphlet illustrating and describing the company's storage battery trucks and the Lakewood trailers for industrial hauling.

The Westinghouse Air Brake Co., of Pittsburgh, Penn., has recently established a house organ known as "Wabco News." It is an 8 x 11-in. 22-p. magazine issued monthly, and is known as the official journal of the employees of the Westinghouse Air Brake Co., and associated interests.

Scientific Advance of the Irrigation Art

IRRIGATION as an art guided by science is progressing. Week before last we published an article giving some of the results of a series of studies on seepage and the duty of water. It appears from a very practical article on algæ removal from irrigation canals, printed last week on p. 382, that scientific observations were made on the kinds of algæ which caused the trouble dealt with. Moreover, one reason why it was necessary to reduce algæ was because they clogged the meters which have been installed on this particular project. Certainly, the science of irrigation is progressing when water for crops is sold by meter measurement and an attack against algæ is directed with the aid of the microscope.

Concrete Shear Tests Should Be Continued

IN SPITE of a number of tests, most of them of long standing, knowledge of shear in concrete is in a most unsatisfactory state. There seems to be little doubt that existing permissible safe values are much too low and that in some kinds of design, particularly in deep beams, this restriction operates with considerable hardship. The series of tests inaugurated for the Emergency Fleet Corporation by the Bureau of Standards, some of which are described by Mr. Slater on another page, went far enough to promise valuable results, not only in the matter of shear, but also in many other properties of concrete. Unfortunately, however, they cannot be continued under the same auspices. The Bureau of Standards is willing and anxious to take up certain lines of this work where it was left off, but it lacks sufficient funds to continue the investigation. It would be shortsighted policy on the part of Congress to refuse the few thousand dollars that are necessary for this work, which, if continued as already begun, should result in a great saving in concrete design. Technical societies and individual engineers might well interest themselves to the extent of writing to their Congressmen urging the necessary expenditure.

Problems of the Profession and the Local Association

FOR some years the movement toward local grouping of engineers has been progressing more or less, under the impetus of the natural need for such grouping, as well as through the efforts of men who saw the importance of this development for the expression of professional interest. The larger national societies have made various advances in local organization, the Engineering Council is studying the matter, and in addition a new association formed essentially as a focus of local groups has come into being. There is a healthy competition between these directive agencies of local organizations which promises well for the progress of the movement. On the subject of the pressing need for active local organizations, independent of the means employed, such comments on the needs of engineers as Mr. Finley's, represented by the extracts on p. 363 of last week's issue, address themselves to all engineers without regard to affiliation. The separated extracts we reproduced, culled from an informal speech, are not to be judged as forming a logical exposition of the profession's situation. They do, however, center unmistakably on the question of better organizing the profession, and point toward the dual purpose of helping the engineer and of enabling the engineer to help the public—his community. Those who know the problems of professional existence and who have learned by their own bitter experience the need for applying the engineering mind to public matters more than has been done in the past will value Mr. Finley's message.

How to Get Local Publicity

RARELY if ever has any engineering society been so lavishly treated by newspapers as to have from five to nine columns per day given up to its papers and meetings, in addition to having the news syndicated and sent to all newspapers of the state. Yet this was done last week by the Muscatine *Journal* during the two-day annual meeting of the Iowa Engineering Society. For six consecutive days previous to the meeting half-column articles about the meeting appeared, and a welcoming editorial contained these significant words: "Reconstruction is the vital responsibility which faces the nation today. Here the engineer is peculiarly qualified to assume a leadership. We must look to the engineer for leadership in the important national and communal projects which contemplate an extension of the opportunities of service." This was the news-peg on which much of the publicity hung. Back of this almost unbelievable result lies a story of a publicity campaign that every engineering society should take to heart. A central committee was coached by an old newspaper editor who handed out simple, usable rules, taking the mystery out of publicity. News-pegs, the importance of strong introductory paragraphs, and other "first aids" to the engineers in publicity, were explained to the committee. It is important to note that this committee then proceeded to bring its influence to bear on the local en-

gineers, not directly on the editor, to whom the members of the committee were total strangers. In the last analysis actual flesh-and-blood contact must be made. The more human it is the better the result. It is said that a certain Muscatine engineer got the better of the editor in a recent fishing contest; at least, it is certain that they go fishing together and know the best holes. Engineering publicity in that city becomes therefore only a question of producing articles, for an understanding has already been reached. The problem of getting engineering publicity in Iowa is well on the way toward solution, and the immediate undertaking, a sustained publicity campaign on the engineers' registration bill, should energize the local engineers into action, thus making a vital link in the publicity chain heretofore largely neglected.

Civilians Did Army's Construction Work in the United States

THIS entire country—and, indeed, all countries participating in the world war—took a keen interest in the performance of the group of men who so speedily built the 32 training camps for the United States Army. The rapid growth of these camps was spectacular and made a deep public impression, but full explanation has never been widely circulated that it was the civilian engineers and contractors of the nation, rather than a regular Army organization, which accomplished this modern miracle. Undoubtedly, it was one of the notable achievements of our military establishment and one of the substantial factors in the winning of the war. As the construction of these camps at a cost of $200,000,000 approached completion, it was preëminently wise for the War Department to have placed, as it did, all subsequent work for the Army in the United States in the hands of the Construction Division.

An account of the wide scope of work, representing about $1,000,000,000, undertaken during the year and ending with the armistice, is given on p. 416. It comes from an engineer who has been one of the Construction Division's technical advisers since the early days of the war, and who has had even better opportunities to view the work as a whole than those closely engaged in the various parts of the program. Not only does the kind and amount of this work interest engineers, but the type of the organization furnishes in particular a just source of pride to civilian engineers. It is significant that there were not more than three regular Army officers connected at any time with the organization—barely enough to guide the huge performances in conformity with Army regulations. Whether or not the men who "did their bit" so effectively wore the uniform of the Army matters not—the outstanding feature of it all is that the rich, practical experience of over a hundred of the most active engineering and contracting concerns in the country was embodied in the organization.

By the untiring, skillful, devoted work of these engineers and contractors, in city, village and wilderness, all over the United States, there arose, as though by magic, camps, munition plants and warehouses. The work of the civilian engineers set free the all-too-few military engineers to win laurels on the fighting fronts of France, the place of their heart's desire. It should always be remembered with gratitude that those who remained in America, in the Construction Division and on other assignments, also served their country.

Internal Fissures in Steel

ANOTHER step forward has been made in our knowledge of steel through the study of "snowflakes," discussed at last week's meeting of the American Institute of Mining Engineers. The new knowledge is, like numerous other items of scientific and practical progress, a byproduct of war activities.

Flakes, interior defects that show as white, rough-textured patches on the fracture, and that apparently destroy the ductility of the metal, occurred with such frequency in the production of shell and cannon steel during the past year or two that, for a time at least, they were almost an epidemic disease. They affected alloy steels, chiefly nickel steel, and in some instances they led to serious failures of machine parts made of this material. But there are reasons for thinking that causes similar to those responsible for flakes in nickel steel may account for some unexplained troubles of much more widely used grades of steel.

Studies at the Bureau of Standards by H. S. Rawdon demonstrated flakes to be minute internal cracks or fissures in the steel. Various facts revealed by the microscope showed that these cracks originated at the time the metal was in the ingot, and probably were due to ingot peculiarities. However, other facts, brought out in discussion, suggested that snowflakes may also be produced at later stages in the history of a piece. It appears that the mechanical or thermal treatment of the metal at a time when it is going through a structural change which makes it temporarily weak is responsible for producing the minute cracks. The question of how flakes originate is by no means fully cleared, but enough has been accomplished to assure further progress. It is within reason to conclude that the facts now being accumulated will lead to methods of preventing or avoiding flake trouble.

So far as yet appears, these flakes concern only metal of the highly special grades used for crankshafts and for guns. But there is the prospect that the studies made have direct bearing on the quality of steel railway rails, and if this should prove true it will give the snowflake question a far wider interest, and probably constitute its main importance. If the most dangerous and elusive defect of rails, the transverse-fissure defect, can be brought under control, railway safety will be increased.

For six or seven years the transverse fissure has been the leading problem in rails. It is a particularly dangerous defect because it does not reveal itself until the rail has broken. Despite extensive investigation and no end of discussion, nobody has yet succeeded in finding what starts transverse fissures, though it seems certain that some local deficiency of quality must have existed at the nucleus of the slowly growing detail fracture which characterizes the transverse fissure.

Microscopic and chemical studies of all kinds failed to show any condition at the nucleus of transverse fissure different from the conditions in the normal rail

metal. Now, however, the snowflake of gun steel, and the discovery that a microscopic crack is responsible for it, throws sudden light on the nature of the transverse-fissure defect. M. H. Wickhorst, who has been studying rail defects for some years in the interests of the American Railway Association, identifies the two defects as strikingly similar and quite probably the same. Careful research will be needed to establish the identification with certainty; nevertheless, it unquestionably supplies for the present a working hypothesis of pronounced value, one which will be a new point of departure in rail study.

It has long seemed likely that progress in our knowledge of ordinary steel would be assisted in a most important manner by the study of high-carbon and special steels. Because of the larger number of variables which these steels contain, their sharply differentiated structure and their wide range of physical and structural modifications, they afford a vastly sharper picture of what goes on in the metal, though at the same time a more intricate and confusing one. The relatively dull aspect of the conditions existing in low-carbon steels, on the other hand, makes more difficult the discovery of physical peculiarities. If, then, the investigation of snowflakes has already reacted on rail study, it may also prove to have a bearing on some of the questions surrounding the structural steels. Should the parallelism of flake and transverse-fissure phenomena be established definitely, it would furnish a new demonstration of the essential unity of steel study.

Outlets Govern Land Reclamation by Drainage

LAND reclamation by drainage requires broader consideration from the viewpoint of finding adequate outlets through the larger elements in the natural drainage system, if it is not to be restricted to small local operations. This may mean extensive stream regulation, extending over two or more states and requiring interstate agreements if not Federal action. How extensive are the areas sometimes involved may be illustrated by Illinois and Indiana examples cited by Edgar A. Rossiter in a paper read before the recent drainage congress in Chicago.

In Illinois the Kaskaskia River passes through 25 counties and has 42 or more tributaries, with a combined drainage area of about 5800 square miles. Each of the 42 tributaries contains a catchment area sufficiently large for the organization of a drainage district, but under present laws no two catchment areas may join in one district, and without doing so full drainage development is impossible. Interstate or Federal action is necessary in the case of the Kankakee River, which drains 54 townships having a total area of 1,046,000 acres in Illinois and 74 townships with 1,695,000 acres in Indiana. Indiana cannot obtain relief until a large interstate drainage district is formed or the Federal Government acts in deepening the Kankakee River. When once the Kankakee River is deepened, the tributaries such as the Iroquois and Yellow Rivers, with creeks approximately 150 in number, will be able to drain this 3,000,000-acre watershed.

The examples described, Mr. Rossiter declares, are typical of every inland river in the Mississippi Valley and also of many of the rivers of the Eastern states. This being so, it is evident that both state and Federal action will be required if Secretary Lane's plan for reclaiming swamp and overflowed lands, now being studied in detail by engineers working under the United States Reclamation Service, is to be realized. Many of the state legislatures now in session should take these matters into immediate consideration, with a view to passing needed remedial measures before they adjourn.

Meeting Problems in Sewer Location

THAT not all the sewage need be pumped has been overlooked in laying out the sewerage systems of some of our seacoast towns. Where the grade is slight and a gravity flow is hard to get, owners of low-lying areas are wont to endeavor to force the decision to a low-level system of trunk sewers for the entire city, delivering to a pumping plant. The popular cry is for a system to serve all areas, making no "discrimination against sections which happen to be slightly lower than other portions of the city." Unfortunately, the political aspect of such situations often beclouds the real problem to the extent that a feasible middle course is not sought.

No such mistake was made in planning improvements recently effected in the system at Santa Barbara, Cal. Two sections of the city were so low that, if they were served by a gravity system, tidal waters would back up into the trunk lines so that discharge into the ocean would occur only during low tide. In fact, in the original system installed to serve the lowest portions of the city, this condition had existed for years, constituting a continual source of annoyance. In planning the recent extensions and improvements to the system, the usual suggestion of a common sump, with a pumping plant to handle the total sewage flow, located somewhere along the ocean front, was proposed to the engineers. They dismissed this, undertook to find a more economical solution, and succeeded. The new system has a comparatively high level outfall which discharges above high-water line and a small part of the sewage has to be pumped up to the main trunk sewer. The trunk lines of the old system serving the low waterfront section of the city were not disturbed, but were tapped by a new line draining inland. This line leads to the other portion of the town, where a small area was below the level that could be served by an outfall above high water. At this second low area a small pumping plant was installed to lift the effluent from both low areas into the new gravity line. A system was thus laid out successfully with a pumping plant just one-tenth the size that would have been required to handle the total sewage of the city. The saving in the cost of operation alone, as compared with that of a pumping plant to handle the total sewage flow, would pay the interest on a $60,000 investment. The entire cost of the extensions and improvements was only about $30,000.

It is by such planning and saving as this that the engineer justifies his professional existence. If the lesson could be borne home to the city fathers of many a community, much good money would be saved.

Operating a Hydraulic Dredge Under Difficulties

After Old Spoil Banks To Drainage Canal Had Slipped, This Type of Excavator Was Only One Available To Dig Out Log-Filled Earth in Channel

By Albert S. Fry
Morgan Engineering Co., Memphis, Tenn.

Hydraulic dredges are not as a rule used to excavate stiff clay material which is filled with stumps, logs and vegetable débris, but a combination of circumstances made this type of digger the best available for some reconstruction work on a cutoff channel of the Bogue Phalia Drainage District in Washington County, Mississippi, where old spoil banks had slipped into the channel. The dredge was nearby and could be had, and, besides, it was the only type of equipment which would insure getting the excavated material far enough back of the banks to prevent a recurrence of the slips.

The channel was originally constructed by a dipper dredge in 1914 and 1915, with a bottom width of 70 ft., an average width of 15 ft. and side slopes of 1 to 1. The excavated material was deposited in spoil banks on either side of the channel, leaving a berm 15 ft. wide between the top of the excavated slope and the channel side toe of the spoil bank. The material, as it was deposited, formed a bank from 12 to 18 ft. high and from 60 to 90 ft. wide on the bottom.

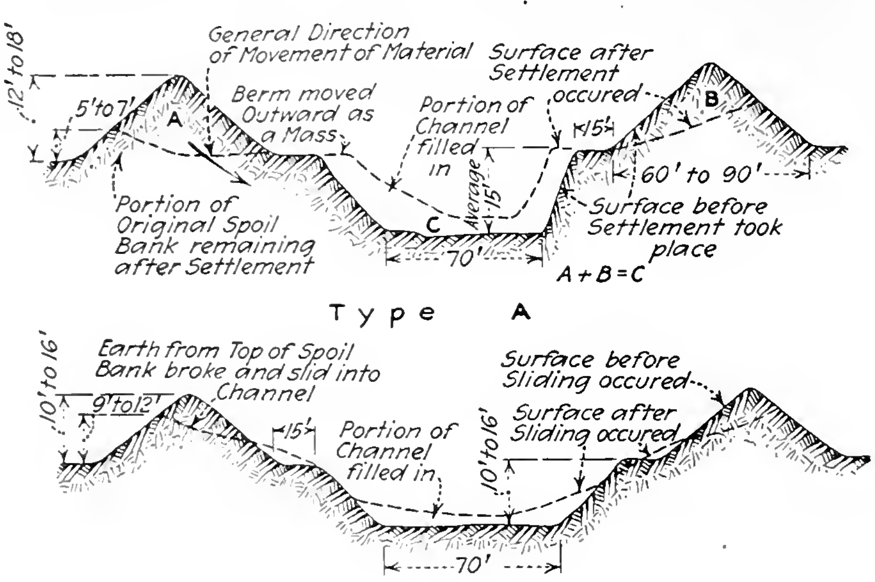
The channel lies for several miles in the bed of an ancient lake, now dry. This lake bed was a cypress brake when the channel was dug through it. At the eastern end of this ancient lake bed the channel empties into an existing lake, through which for about a mile no excavation was necessary. Going out of the lake, a channel was excavated for about a mile and a half to an outlet in another lake, which in turn emptied into a river.

Within about six months after the original excavation, earth movements occurred in the spoil banks that resulted in filling in the channel for a distance of about a mile below the lake and for about the same distance above. These movements were of two distinct kinds.

The Two Kinds of Movement

The first kind, which began about a quarter of a mile above the lake and extended for about three-quarters of a mile further upstream, is designated as type A in the accompanying diagram showing the character of the movement. The greater part of both spoil banks settled down, resulting in a crowding in of the sides and a pushing up of the bottom. The great weight of the spoil bank pressing downward on the original earth under the spoil bank resulted in this earth below the original surface giving way along some plane of rupture and forcing the material into the channel. At the place of greatest movement scarcely 50% of the original area of the channel prism remained. Along some portions of the channel the restriction was greater than at others. One noteworthy and remarkable feature of this movement was the fact that the entire berm moved bodily outward along both sides of the channel, the outer margin of the berms lining up as evenly after the movement as before. The earth comprising the berm at the surface, and for some depth, must have moved outward as a mass. Stumps in the earth on the berm were absolutely undisturbed by the movement.

Another peculiarity about the settling of these spoil banks was that it occurred only along the banks of



TWO TYPES OF BANK SLIP ON DRAINAGE CANAL

three-quarters of a mile of the channel, whereas along some four and a quarter miles where the excavation and spoil banks were of the same or even somewhat greater size no movement took place. Borings taken preceding the excavation, and an examination of the spoil banks after excavation, disclose no difference in the character of the material excavated. The weight of the spoil banks could have been no greater than elsewhere. As a matter of fact, some of the banks which settled were smaller than some which did not, and hence must not have had as great weight. For unknown reasons, less cohesion between the soil particles must have existed along the banks which settled than along those which did not.

The second type of spoil-bank movement occurred in the mile below, and for a quarter of a mile above, the lake, and is shown as type B in the diagram. In this case the high, steep spoil bank ruptured and slid into the channel and onto the berm, carrying with it into the channel a part of the berm. Where large spoil banks are deposited by dipper dredges, such earth slides are not uncommon, especially if the excavation is through earth upon which has been growing cypress or tupelo gum. In this case, the channel had been dug through a cypress swamp. Earth slides of this nature are ascribed to the excessive weight and steep side slopes of the spoil banks resulting from the concentration of the material due to the limited spoiling capacity of the machinery.

The cutoff channel had been designed to carry flood waters that would otherwise overflow and damage valuable agricultural lands. It was therefore a matter

WOODEN PONTOONS SPECIALLY BUILT TO CARRY SPOIL PIPE

CUTTER HEAD OFTEN CLOGGED

of immediate importance to redredge the channel so that it would have the capacity for fulfilling its intended purpose. It was found that about 116,000 cu.yd. of material would have to be taken out.

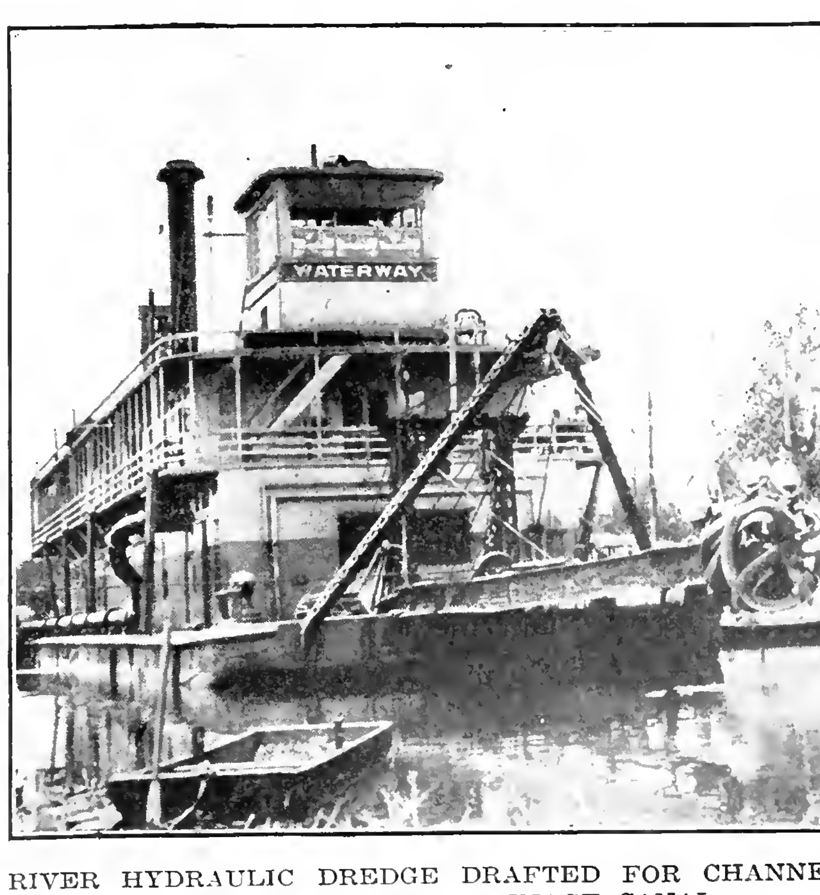
Selecting the equipment to do the work offered a considerable problem. The dipper dredge that had made the original excavation had been removed from the work. To install another dipper dredge, or a dragline or cableway excavator, of a size adapted to the work, would have been costly. Furthermore, these types of excavators were looked upon with disfavor in the present case because of their limited capacity for spoiling material, for it was not desired to trust any great concentrated weight of spoil bank on material that had already moved in the manner described.

The cutoff channel empties into the Sunflower River, a navigable Government stream, and it so happened that a United States Government hydraulic dredge, the "Waterway," was just finishing some Government work in the vicinity of the mouth of the filled-in channel. Negotiations were entered into which finally resulted in the renting of the dredge by the Drainage District to do the redredging. It was recognized from the outset that the excavation, which consisted of stiff clay or gumbo soil in which were many buried logs and stumps, was far from ideal for a hydraulic dredge, and that the costs of the work would be higher than for ordinary hydraulic dredging. However, the hydraulic dredge was immediately available, and by hydraulic dredging the excavated material could be spoiled over a wide area, so that all danger of recurrence of the earth slipping would be averted. These factors more than overbalanced the difficulties which it was anticipated would be encountered in doing the work by hydraulic dredging.

The "Waterway" is a stern-wheel steel-hull dredge, 163 ft. long and with a beam of 37 ft., a depth of 7 ft., and a draft between 3 and 4 ft. The centrifugal dredging pump is driven by a nonreversing triple-expansion engine, 10, 16, 26, by 12 in. The pump runner is 50 in. in diameter. Steam power for operating the dredge is furnished by two horizontal Mississippi River type boilers. The suction head is equipped with an eight-blade spiral cutter head 4 ft. 9¼ in. in diameter. Leading from the pumping engine, which is near the bow of the boat, are discharge pipes of 16-in. diameter which terminate, one on each side of the boat, some 10 ft. above the level of the lower deck. The discharge can be turned into either pipe as desired.

When the dredge operates in large streams or rivers, for which operation it was designed, a line of floating discharge pipe connects onto the discharge pipe from the pump, these floating pipes being supported by steel pontoons which float alongside and back of the boat. But the Bogue Phalia channel was not wide enough to allow the dredge to operate with the pontoons floating alongside the boat, so it was necessary to modify the discharge equipment before excavation could begin. By a special pipe arrangement, the starboard discharge pipe was joined with a line of pipe clamped at the outer edge of the starboard guard on the boiler deck of the dredge. At the stern of the boat a special "down-and-out" offset pipe connected the pipe on the deck with the floating line.

The steel pontoons and discharge pipe used by the "Waterway" in river work were also too large to permit of their use in the channel to be redredged, and



RIVER HYDRAULIC DREDGE DRAFTED FOR CHANNEL CLEARING WORK IN DRAINAGE CANAL

wooden pontoons, 13 ft. long by 7 ft. wide by 2 ft. deep, were built to carry a line of floating pipe in sections 16 ft. long. The floating pipe was connected by rubber sleeves 24 to 36 in. long. To connect with the floating line, shore pipe in 16-ft. sections with telescope joints was provided.

MATERIAL WAS MOSTLY DELIVERED IN LUMPS

Another preliminary which had to be undertaken was the construction of a dam across the lower end of the channel, to maintain a sufficient stage of water for operation of the dredge. This dam consisted of two lines of rough Wakefield piling driven about 25 ft. apart, and supported by a system of round piles which were braced from one to another horizontally and diagonally. To tie the sheeting together, 1¼-in. steel tie-rods were used. Between the piling, an earth fill was placed by the dredge itself. A crown was eventually put on by wheelbarrows after the hydraulic fill had settled. The dam was about 100 ft. long, and during the course of the work withstood a maximum head of 14 feet.

In the filling of the dam, a blowout occurred downstream which resulted in a sinking of the fill within the dam. To prevent further trouble from blowouts, material was pumped in to form an earth fill against the lower leaf of the dam. This was successful and no further blowouts occurred, although some trouble was experienced at a later time from slipping of the earth fill below the dam, due to the water being drained away from the lower side of the dam. Some short sheetpiling driven near the toe of the fill proved effective in preventing further slipping.

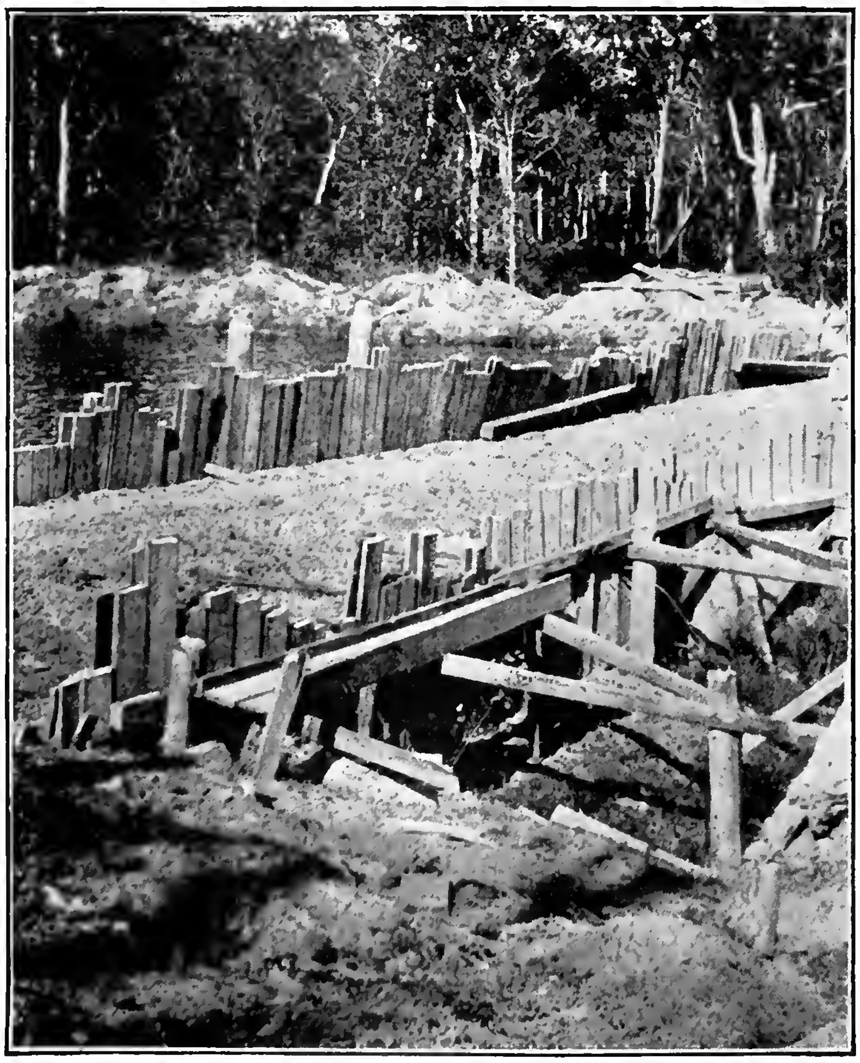
While the work was being carried on, the water pressure against the dam, combined with the settling of the material in the dam, caused the upstream sheeting to lean downstream. As a safety measure to guard against further movement, cables were attached to each end of the sheeting about 15 ft. from the ends of the dam, the cables leading upstream to trees along the bank. These cables were not called into play, however, as the sheeting did not move after they were in place.

Some seepage developed along the tie-rods, but this was stopped by ramming and puddling material around the rods.

Around one end of the dam, a spillway to carry away the flow in the main channel was blasted and dug through the existing spoil bank into an adjacent slough, returning to the main channel by a similar ditch through the spoil bank below the dam. Considerable trouble was experienced with this spillway, as the water cut badly into the spoil bank nearest the dam and threatened to wash out the end of the dam. Sacks filled with earth were first used to stop the cutting, but these were only partially successful, as the current proved strong enough to wash away many of the sacks. Wing dams or breakwaters, made of brush in combination with sacks, proved to be the best means of holding the spillway channel from cutting.

After the excavation work was completed, the temporary dam was removed, so that the dredge could return to the Sunflower River.

The excavation work was performed in two shifts of eight hours each, one working from 4 a.m. until noon, and the other from then until 8 p.m. Each shift consisted of an engineer, a leverman, an oiler, a water tender, a stoker, and from six to 10 deck hands. The captain of the boat superintended operations, being assisted by a mate. A pilot made up the remainder of the crew, excepting the cook, the laundress and the cabin boy. In addition to the dredge crew, a shore gang of from 10 to 12 men was required to blast and remove logs and débris ahead of the dredge. Considerable difficulty was experienced in keeping full crews, owing to the drafts of the Army and the general spirit of unrest



TEMPORARY DAM BUILT TO MAINTAIN ENOUGH WATER TO FLOAT DREDGE

caused by the war. This condition no doubt had its effect on increasing somewhat the cost of the work.

The excavation required the removal of material from the bottom and sides of the channel. In the digging position, the boat was held steady by a central spud just in front of the stern wheel. By means of a cable passing over sheaves on the ladder frame and stretched across the channel ahead of the boat—this cable being anchored at each end to a dead man laid in trenches on the banks—the boat was swung across the ditch on an arc of which the spud was the center. Raising and lowering the cutter head ladder provided the vertical movement necessary. Ordinarily, the dredge could perform the excavation entirely across the ditch from one anchoring of the spud, but in some places, where excavation was heavy and work was carried close in to the bank, two set ups were necessary.

The material that had to be excavated presented a difficult task for a hydraulic dredge. The original excavation had been almost entirely through wooded country, and the logs and slashings on the right-of-way for the channel had been piled beneath the spoil banks. When the slides occurred, much of this débris, together with stumps, was carried along with the material that encroached on the original channel section. The material itself was a stiff clay or gumbo soil.

Preceding the dredge excavation, the shore gang blasted out and removed as many of the buried stumps and logs as was possible. This task was surrounded with difficulties. The logs and débris that had been under the original spoil banks formed a matted mass that was extremely hard to remove. It was impossible to blast all of the logs and stumps, and many remained which had either to be "nosed" out by the cutter head or chewed up by it.

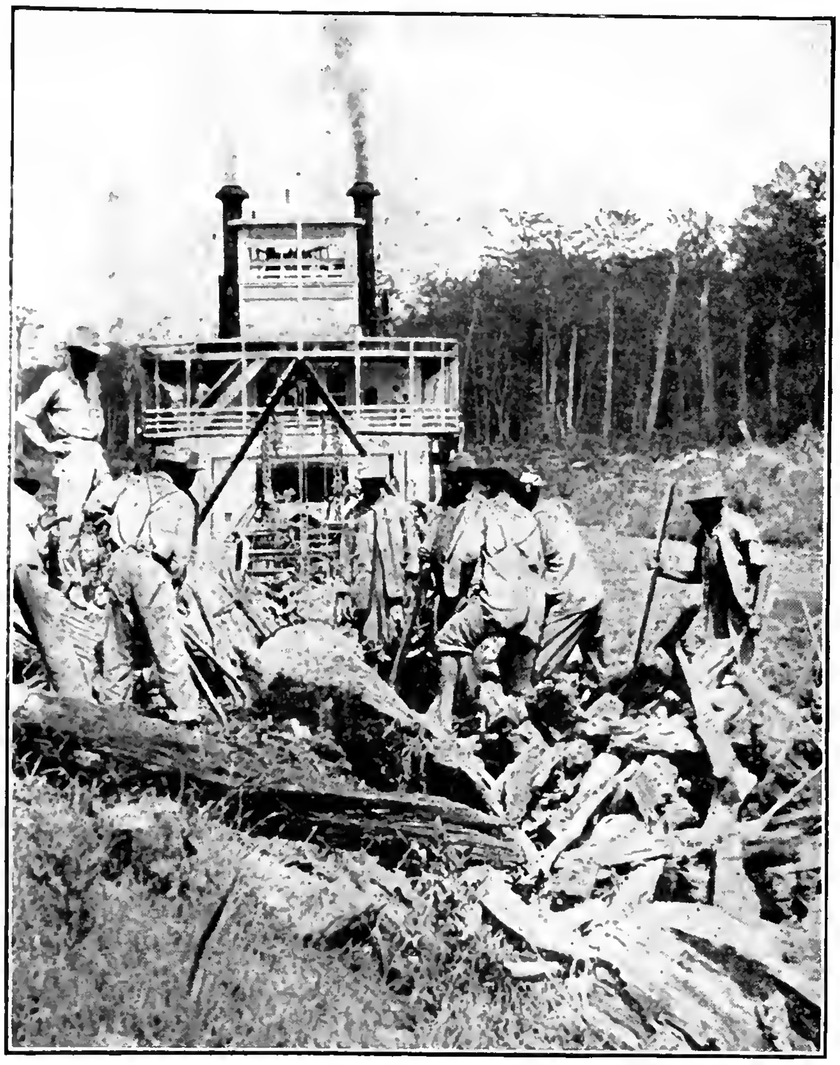
Floating ahead of the boat was usually a thick mass of chunks, made up for the most part of heavy pieces of stump or logs mixed in the material. These chewed-up pieces of logs and stumps, together with chunks and roots, gave endless trouble from plugging up the pipe line, and delayed the work considerably. The trouble from floating chunks was finally mitigated to a large extent by clearing these out of the way by means of a floating boom. The boom consisted of short pieces of logs held together by a cable. With a boom of this kind, the chunks could be worked to the rear of the dredge and then held against the bank by the fastening of the ends of the cable to the bank.

During part of the digging a great many cypress stumps, knees and roots were encountered, and no difficult excavation can be imagined for a dredge of the "Waterway" type than cypress stumps, knees and roots.

The material itself also gave trouble, the nature of which can be seen from the view of the clogged cutter head. The stiff character of the digging resulted in the clogging of the cutter head so that it had to be cleaned at intervals by the deck hands with bars and shovels. Removing this material from the cutter head usually required from 20 min. to an hour. By reversing the cutter-head engine at full speed, the material could be shaken loose in about 4 min., but this method was very hard on the machinery and had to be abandoned for that reason.

The excavated material was pumped through the floating line of discharge pipe to the line of shore pipe. In order to discharge the material behind the existing spoil banks, trenches in which to lay the pipe had to be dug and blasted by the shore gang in advance of the dredge. These trenches were made along one side of the channel only as all of the material was spoiled along one side.

When excavation was started after the shore pipe was laid in a new trench, the floating line was formed in a half circle from the stern of the boat to the shore connection. As the dredge moved ahead, the floating line straightened out until it formed nearly a straight line from the stern to the shore-pipe connection. Either more pontoons of floating pipe would then have to be inserted in the line, or the shore line would be moved forward. Usually, a movement of 200 to 300 ft. forward was made before shifting the shore line.



ILLUSTRATING THE KIND OF MATERIAL THAT HAD TO BE REMOVED

The head pumped against varied from 8 to 15 ft. When the floating line was short, this head did not cause any trouble, but when the floating line stretched out to 300 or 400 ft., only frequent flushing and alertness to forestall buckling at the rubber sleeve joints would prevent a plugged discharge pipe.

Apparently, but little of the dredged material was discharged in solution. The spoil consisted principally of balls of mud ranging in weight from a few ounces to several pounds. This material assumed a slope of about 15 or 20 to 1, and where the original spoil bank was low, and the redredging heavy as a consequence, the material formed a continuous well drained deposit wherever the lines of shore pipe were not spaced more than 200 ft. apart.

Repairing the main spud, which was broken twice,

constituted the chief item of repairs that were made during the work.

After it broke the first time, a 70-ft. gin pole was rigged on the bank of the channel to replace the spud, the timbers for the gin pole being cut out of the nearby woods. The spud itself is about 40 ft. long. A green elm stick cut out of the woods was used for replacing the first spud. After a couple of weeks' service this broke. The gin pole had not been taken down after the first new spud had been put in, so the second was put in without much difficulty. For this spud a seasoned gum timber was used. This proved serviceable, and no further trouble was experienced with the spud.

At the close of the job it was necessary to replace some of the principal parts of the cutter-head engine which had worn out during the work, due to the hard service performed by the engine.

Progress and Cost

Records were kept during the entire period of operation of the dredge. The dredge was on the work a total of 141 days, of which 120 were working days, Sundays and holidays being excluded. Of the working days, 12 were occupied in modifying the discharge equipment, filling in the dam and making repairs, leaving a total of 108 days when dredging was done. A total of 116,400 cu.yd. was excavated at an average rate of 1080 cu.yd. per day of 16 working hours.

Delays consumed 30% of the total available dredging time. These delays were of three general classes. Necessary operations of the boat, such as moving the boat, moving, extending or repairing the discharge line, and adjusting machinery, comprised 13% of the total time consumed.

The character of the material excavated caused delays for removing snags, chunks, roots or other débris which lodged in the cutter head, the suction line or the discharge line, and which took up 10% of the total time. Major repairs delayed the work 7% of the time.

It had not been expected that the cost of the work would compare favorably with usual hydraulic dredging costs, owing to the difficult conditions under which the work was done. The cost of the work, excluding supervision, engineering and overhead charges, was 41.7 c. per cubic yard. This was made up of the following items:

A. Preparatory and Incidental Work		
1. Additional equipment and preliminary work	$0.054	
2. Dam and spillway	.038	
3. Clearing and grubbing	.031	
4. Passage through bridge	.004	
5. Transferring boat to river after work was completed	.020	$0.147
B. Dredge Operation		
1. Rent	$0 084	
2. Labor	.070	
3. Subsistence	.037	
4. Coal	.056	
5. Supplies	.009	
6. Repairs	.010	
7. Incidentals	.004	.270
		$0.417

In connection with these costs, it must be borne in mind that the work was done during the summer of 1917, and that materials and labor had not reached the high figures which they did several months later.

The entire work was carried out under the supervision of the Morgan Engineering Co., of Memphis, the direction and planning of the work being done by Ned H. Sayford. T. P. Anderson was resident engineer and Capt. R. N. Ferguson, of the dredge "Waterway," superintended the dredging operations.

Civil War Price Trends Compared With Those Today

Judging By Past, Prospect Is That High Prices Will Continue—Should Not Retard Immediate Building

By Morris Knowles
President, Morris Knowles, Inc., Engineers, Pittsburgh, Penn.

PRICE movements in the next few months and years will have a serious effect on all construction activities; more than that, the expectation of lowering prices is one of the leading causes of the present lack of construction. As a result of a study of numerous factors that go to make up prices, and particularly of the periods following previous American wars, especially the Civil War, it seems to the writer that the trend of prices probably will not be downward as rapidly as some hopeful minds indicate.

The question of whether prices will fall soon, how far they will go down, and how rapid that decline will be, are problems which cannot be accurately solved. And any assumption which can possibly be made as to the probable trend of prices during the next few years may be shown in the future, when one can gaze with a perfect hindsight upon the past, to have been nothing short of a wild guess. However, it has been the practice of engineers and those accustomed to plan for the future not to be fearful of later condemnation in making estimates. It has been the practice of the engineering profession to gather all data which affect the particular problem at hand, to study the effect of such conditions in the past, and to apply the expected results of similar conditions to the future Then the future can be projected and predicted, with the imperfect vision which all men must have of the events of tomorrow.

No Index Numbers for Construction Material

One of the best means of measuring the trend of prices is that of "index numbers," which are the sums or averages of the prices of a number of commodities referred to a given year as a base, usually noted as 100. However, no standard index numbers exist for engineering construction. There is shown in Fig. 1 a diagram comparing Dun's index numbers of 200 commodities, with a curve of index numbers made up from a study of about 25 construction materials. The diagram shows that while the relation between the general index numbers and an engineering index number for construction work is not exactly the same, for all years they would probably vary in their trend quite closely, and, therefore, general index numbers may be used in a general way for this purpose of studying the trend of construction prices. Fig. 2 shows curves of index numbers for the periods before, during and after the Napoleonic and the Civil Wars, and also from 1884 to date. These are arranged so that the peak in each case coincides with 1918, which is considered the peak of the present war. It will be noted from this diagram that it was

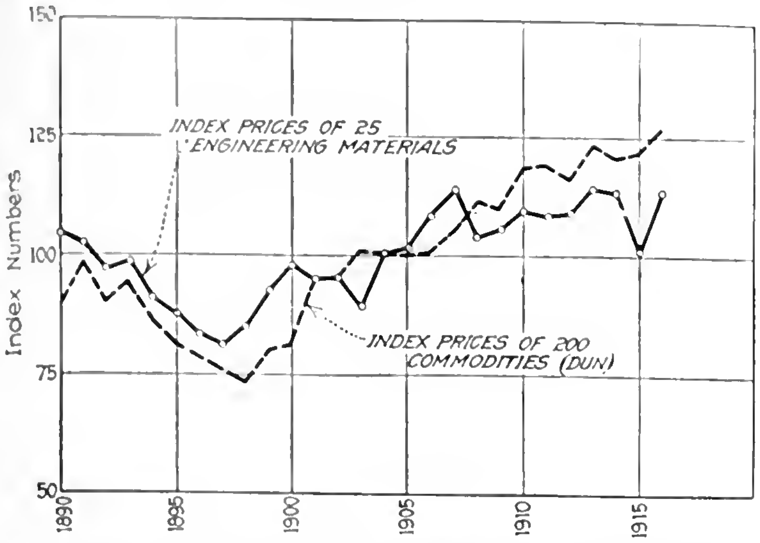


FIG. 1. PRICES OF GENERAL COMMODITIES SHOW ABOUT SAME TREND AS INDEX COSTS OF BUILDING MATERIALS

generally many years after the wars before the prices recovered completely from their increase. After a study of the trend of prices following previous wars and considering the conditions which have obtained at those times, it is believed that the curve which can be applied to American conditions as seen today is that of our Civil War in 1860-65. Even in this case, comparisons must be made with extreme care, and subject to many modifications. After the Civil War it was not until 1878 that the price level was as low as it was in 1860, or a period 13 years after peace was declared.

In order that we may intelligently apply the experience of 1865 to that of 1918 and the years following each, it is necessary to consider the economic conditions which existed at that time as compared to those of the present; and a word concerning each may be advisable, without attempting to discuss intimately all the data used in reaching conclusions.

It may appear, first, that the change in prices following 1913 was considerably greater than the corresponding change following 1860. However, this is more apparent than real. The difference is lessened when it is considered that the Civil War occurred during a period of falling prices and the present war occurred during a period of rising prices, so that the angle of the change of direction of the two curves is probably about equal.

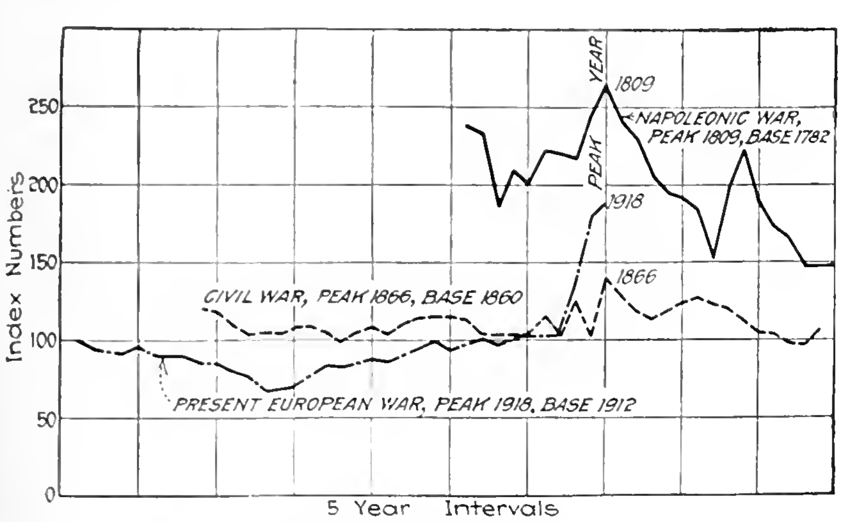

FIG. 2. COMPARISON OF INDEX PRICES FOR PERIODS DURING AND FOLLOWING RECENT WARS

Data as follows: Napoleonic War—Jevons. Civil War—United States Bureau of Labor. Present War—United States Bureau of Labor.

One of the important factors in the trend of prices is the labor market, and although statistics are not very accurate as to the amount of labor that has been withdrawn from ordinary pursuits during the war, yet from those data which are obtainable, as compared with the figures during the Civil War, it is indicated that probably a greater percentage of labor was withdrawn for actual military service during the Civil War than during this war. But the interference with the supply of labor today is far greater than it was during the Civil War. While the men withdrawn for military service constitute a smaller proportion of the population than they did for armies of the Civil War, "the men behind the men behind the guns" are many times as numerous, and there may be much difficulty in readjusting these men to a peace basis, if lower wages are to be offered. Interference with immigration has been far greater during the present war and is likely to continue longer after its close. Sufficient data on the participation of women in industry are not available for comparison of the two periods.

The diversion of capital to distinctively war industries has been on a vastly greater scale in the present war, and the process of restoring it to peace industries at the end of the war will be proportionately slower and more costly than in 1865. The absence of free land, on which to set to work the returning soldiers and the laborers released from war industries, will greatly increase the difficulties due to readjustment.

The nature of the foreign trade of this country at the outbreak of the European war has brought to it an amount of gold far in excess of its normal share of the world's supply. On the basis of this gold, the amount of paper money in circulation also has increased. It is this increase in money, reinforced by similar increase in credits in bank loans, which has been one of the most influential factors in the present price situation.

Owing to abnormal conditions prevailing in the countries in which the larger part of the trade with the United States has been carried on in the past, there is but slight prospect that normal conditions of money and credit will be restored, or that the trade balance will be reversed by sending gold abroad to pay for goods. It is probable that the present trade balance will prevail for some time.

As modern industrial society has abandoned the individualism of the middle of the past century, the new practice of coöperation of producers and regulation by governmental authorities will tend to stabilize prices and retard their movements in either direction, upward during the war, and, it is expected, downward after the war. Price-fixing has been recognized for a long time among public utilities, and the recent experience during the war may lead to continued governmental action along the same lines as regards food and other essential products.

The import tariff will also be used, as it has been used in the past, to protect the high prices existing in America, and as labor is organized and will relinquish its present high rates very slowly, it is probable that this factor, together with the tariff, will be used for a long time to help maintain the present high price level. Any expectation that a fall in prices, even due to panic conditions (unless unusually severe) will result in a return to anything like those which obtained prior to the war, will evidently result in false hopes. Witness the panic

of 1871-1873; while producing a small lowering in prices, it did not bring them to anything like the level which obtained in 1861 or again in 1878 to 1880.

In view of these conditions—namely, upward trend of prices previous to the war, difficult labor conditions, immobility of capital, foreign trade balance, price-fixing and the protective tariffs—it is believed that the period of high prices will continue for a longer time after the period of the present war than it did after the Civil War. If panics and the like are to be averted, with other unrestful and undesirable economic conditions, public works should be started, rather than that we should sit tight and wait for prices to come down, in the hope that this reduction in prices will be very soon. It is doubtful if such reduction will occur within the near future to any marked degree, unless factors other than the economic conditions now prevailing come into play.

The Construction Division of Our Army

A Description and Interpretation for Engineers and Laymen of a Great Organization and the Works It Built—On Nov. 11, 1918, Some 1480 Civilian Engineers Were Putting Through a $1,200,000,000 Program

By George W. Fuller
Consulting Engineer, New York City

UNFORTUNATELY, most members of the engineering profession fail to record adequately their work so that it may take its proper place in the mind of the layman. This could not be more strikingly evidenced than by the fact that there is just being completed an engineering work probably unequalled in the history of the world, but which, as regards the organization doing it, has left so little mark on the mind of the average person that its very existence is almost unknown. When the armistice was signed in November, 1918, 1480 constructors—engineers in the broadest use of the term, and not in its military sense—were wearing the uniform of the United States Army and under the name of the Construction Division were carrying through a building program involving $1,200,000,000, marvelous in its extent and doubly wonderful in the speed and comparative economy of its execution.

The Panama Canal took 10 years to build and cost about $375,000,000. The work of the Construction Division of the Army in one of the early months alone amounted to almost twice the volume of work done in any year at Panama, not only in money expended. but in materials handled, and this, too, at a time when men and materials were most difficult to procure and when transportation facilities were frequently paralyzed.

Many persons who have knowledge of the performance of any part of this building program, seem to be, through the confusion of the work of the military engineer and that of the Construction Division, under the general impression that this work was done by the Corps of Engineers of the United States Army. It should be clearly set out that the Corps of Engineers during the world war was charged almost exclusively with construction work in France while, on the other hand, all of the construction work fof the Army in this country has been and is under the direction ot the Construction Division of the Army, which was also responsible for the design and operation of all cold-storage and refrigeration plants in France.

Civilian Engineering

To appreciate better the immense value of the civilian engineer in this building program, a clear distinction should be made between the duties of the military engineer and those of the Construction Division. The training and practical experience of the military engineer have been along the lines of pre-war fortifications—trench digging, field bridging, mining, sapping, military railways, and other activities generally classed as combatant work. The Construction Division of the Army is that bureau of the War Department which is charged with the entire construction work of and for the Army in the United States, including the Hawaiian Islands, the Philippines, Alaska, Porto Rico, and the Canal Zone. This includes not only the design of the projects, but the procurement of the necessary materials and labor and the supervision of the work itself as regards construction, operation and maintenance. This work calls for men of wide experience in commercial building projects, men who are familiar with the most up-to-date methods of modern planning and building construction in all its phases, including the operation and management of public works and utilities.

Only Three Regular Officers in Division

The Construction Division is a combination of the civilian engineer, the architect, the town planner and the builder, dealing almost entirely with problems similar to those met in the usual lines of construction work carried on during times of peace. An interesting fact bearing on this is that throughout its existence the Construction Division has not had connected with it more than three officers of the regular Army out of a total commissioned personnel of 1485.

The work of the Construction Division of the Army commenced in May, 1917, under the name of the Cantonment Division of the Quartermaster General's Office. The problem at that time was the building of 32 camps and cantonments for the new National Army and Federalized National Guard. Upon the completion of this work in the fall of 1917, the Secretary of War decided that it would be for the best interests of the Government to consolidate all construction work of the Army in this country under one responsible head, that of the Cantonment Division.

The construction projects were necessarily scattered throughout the whole United States, involving problems of transportation not only of materials but also of the necessary workmen.

At one time 200,000 men were employed in the field alone. The work, exclusive of maintenance and repairs, included about 530 operations at 450 different and

widely separated locations. On many projects transportation and living facilities were utterly lacking and required the building of roads and railroads and the providing of living accommodations for the workmen before actual construction could start. In other cases not only was this true, but it was necessary first to clear sites for the work in what were practically forests.

The housing accommodations comprised about 40 large camps and several hundred minor projects, providing accommodations for about 2,250,000 men. In connection with the large camps and the smaller projects as well, in addition to the housing, there were provided the necessary supplementary buildings and utilities. In the case of the major camps practically a complete city was built, including roads, walks, electric lights, water-supply, sewers, sleeping quarters, mess halls, lavatories, theaters, post-offices, store buildings, telephone and telegraph offices, power houses, laundries, storage buildings, hospitals, stables, garages and ice plants.

Army bases, interior posts, expeditionary depots, warehouses, terminal piers, wharves and docks have been constructed along most modern lines and on an hitherto unequaled scale. The areas total 27,502,300 sq.ft. of warehouses and pier sheds and 2,176,000 sq.ft. of open sheds, giving a grand total of substantially 30,000,000 sq.ft., or 690 acres, of storage space. The magnitude of this total can best be conceived by considering that it equals a building 70 ft. wide and 80 miles long or about equal in length to the distance from New York to Philadelphia. Most of the warehouses are of reinforced concrete. These figures do not include miscellaneous warehouses or magazines, or those at camps, or used exclusively by the Ordnance Department. Adjacent to the terminal piers and docks there are completed or well advanced 39,000 lin.ft. of wharves, equivalent to 7.4 miles, for loading ships. This wharfage provides generally for channels with a depth of 35 ft. at low tide and is sufficient to berth 65 ships at one time on the basis of 600 ft. in length of wharf per ship.

There have been built about 844 miles of railroads, exclusive of local trestles, etc., and about 1061 miles of roads, of which a large percentage are of concrete.

The hospital section has built or reconstructed buildings to accommodate 121,000 patients' beds, and in addition has provided quarters for about 12,000 nurses, 24,000 enlisted personnel and 4000 doctors. As in the case of camps, on many hospital projects it was necessary to install all utilities, such as sewers, water, gas, electricity, roads and railroads. To picture the extent of hospital construction, it may be said that if all these Army hospital capacities were consolidated there would result a population about equal to that of Worcester, Spokane or Memphis.

Work for Ordnance Department

For the Ordnance Department alone, there have been built more than 7,933,000 sq.ft., or 181 acres, of industrial and storage buildings, about 7000 lin.ft. of docks and about 3,250,000 sq.ft. of magazines. The work for the Ordnance Department and the Chemical Warfare Service has aggregated a cost of about $150,-000,000, of which the following is a brief description:

Six artillery proving grounds, of which the largest, at Aberdeen, Md., contains about 38,000 acres and has cost about $15,000,000. These proving grounds are used to test all guns, from trench mortars to railway mounts and the 16-in. coast-defense guns, as well as for testing ammunition of all kinds, including the various types of gas shell. They are provided with steel and brick machine shops equipped with electrically driven machinery, including overhead cranes, etc., for assembling and repairing artillery.

Seven ammunition storage depots, of which the largest, at Raritan, N. J., contains over 90 fire-resisting magazines, has a storage capacity sufficient for nearly $400,000,000 worth of explosives and cost about $12,-000,000. Most of these depots are provided with extensive dock facilities and from 20 to 30 miles of railroad sidetracks.

Various fire-resisting buildings of steel, brick, reinforced concrete and hollow tile, together with miscellaneous machinery, were provided at nine of the permanent Government arsenals, which are scattered from New England and the Atlantic coast to California and Texas. There is no uniformity in the requirements of this permanent arsenal construction but in several cases it has run into considerable money. At Watervliet, for example, it included a steel and concrete machine shop about 250 x 600 ft. in plan and other buildings of like character, which added about 4000 employees to the manufacturing force at that point.

Nine Ammunition Assembling Plants

Nine plants were built for assembling ammunition, etc., including shell-loading plants for fixed ammunition, bag-filling plants for loose ammunition, two cartridge factories, one plant for loading aërial bombs and one for manufacturing incendiary bullets. Several of these installations cover three or four square miles, with 300 to 500 separate buildings in one plant and 30 to 40 miles of sidetracks, besides power station, machinery and equipment of all kinds. Much of this machinery, and to a large extent the operating buildings themselves, have had to be designed especially for their purpose.

Twenty chemical manufacturing plants, with their buildings, facilities and equipment, for the manufacture of T.N.T., picric acid, tetryl, toluol, sulphuric acid, phosphorus, mustard gas, tear gas, sodium cyanide and liquid nitrogen, were built. These plants cost from $1,000,000 to $13,000,000 each, and in most cases included housing facilities for the operating forces, as the plants were necessarily isolated.

The Edgewood arsenal, at Edgewood, Md., includes a plant for producing chlorine and other gases, many times larger than any other in the world, an extensive gas-shell filling plant, fire-resisting barracks, two hospitals, a 600-ft. dam and reservoirs, and a 20,000-kw. power station, costing in all about $25,000,000.

Various factories or factory additions were built for the manufacture of Liberty motors, tank tractors, automatic pistols, etc., and various laboratories and experimental stations.

The work of the Construction Division, summed up briefly, has covered such diversified projects as camps, cantonments, wharves, docks, forts, arsenals, great port

terminals, reserve storage warehouses, hospitals of all sizes and description, aviation fields, proving grounds, embarkation camps, engineer camps, gunnery schools, housing, lighters, power plants, factories, additions to manufacturing plants, munition plants, and special new plants, for the production of nitrates, phosphorus, T.N.T. and miscellaneous acids, gases and explosives.

Relations with Other Branches of Service

By the autumn of 1917 the necessity for munition plants, for aviation fields and training schools, quartermaster storage depots and terminals, for powder plants and magazines, for factories, as well as special camps and training schools, was most urgent throughout the country. Every bureau of the Army had developed or was attempting to develop an organization for the construction work required by the program of its own particular activities. This resulted in competition between the various bureaus, not only in the markets for labor and materials, but also in the field of experienced builders, engineers and other similar technical men. There arose in these bureaus constructing organizations and engineering departments whose work it was naturally impossible to coördinate, and there resulted the inevitable loss in efficiency.

The combining of the building activities of the War Department thus became necessary, quite naturally, and, each bureau having its own organization, there also arose the need for a decision as to which bureau should be charged with the construction program on this side of the Atlantic.

The Cantonment Division at this time included officers principally from the Quartermaster Corps, as well as others from the Ordnance Department, the Corps of Engineers and the Signal Corps. This condition was due to the fact that very early in the war the entire commissioned personnel allotted to the Quartermaster Corps was exhausted, and those in charge of building up the Cantonment Division requested that the men selected by them from civil life should receive commissions in other corps, where commissions were available, and then that these men be transferred to the Construction Division. Although an understanding of the procedure makes it clear that such men of the Signal Corps, for instance, as well as those of the other corps, were not trained in the special work of the bureaus in which they were commissioned, but were essentially Cantonment Division men, nevertheless, various bureaus have been inclined to feel that they were perhaps partly responsible for the remarkable achievement of the Cantonment Division. And there has been a desire on the part of other corps to be charged with the responsibility for this construction work.

Between the Construction Division and the several bureaus of the Army for which work was being done there existed a most friendly and helpful spirit. All were concerned principally in expediting the work, and each lent to the other every assistance which would be of value in winning the war. In the case of the Signal Corps there were certain specialized types of construction wherein the men of the Signal Corps could probably benefit by experience in these specialized activities —as, for example, in the construction of balloon and airplane sheds—and these special building activities were not at that time taken over by the Construction Division.

The Construction Division sprang from the Construction and Repair Branch of the Quartermaster General's Office which, when this country became a participant in the world war, was composed of three regular Army officers with a force of 20 clerks and stenographers and about as many engineers, architects and draftsmen. The cantonments were built without making substantial demands on the Engineer Corps for reserve officers, as they were built essentially by civilians, many temporarily in uniform and most of them coming from 41 previously established engineering organizations and 61 contracting organizations. The design of the original cantonments, as regards general plan, was carried on in the Washington office where, up to July 1, 1917, there was only one Engineer Reserve officer. Among the original constructing quartermasters for the 16 cantonments, there was no Engineer Reserve officer, while at the 16 National Guard camps eight of the constructing quartermasters were Engineer Reserve officers.

The Construction Division has reported direct to the Chief of Staff since February, 1918, and it is essentially a part of the Office of the Chief of Staff; in that respect it is substantially on the same footing as any other department or corps of the service. The Army appropriation bill provides funds for the Construction Division through the Quartermaster General's Office, although the latter has no jurisdiction over these funds. It seems unfortunate that in the rush of its crowded program of work the Construction Division did not take the necessary steps to adopt a distinguishing insignia and thus establish in the mind of the public the individuality to which it is so abundantly entitled.

Growth and Development

The organization of the Construction Division, formerly the Cantonment Division, has been a matter of general growth and development, as its duties have broadened. From the four original branches of construction, engineering, materials and accounting, the division has been divided into seven branches as follows: (1) Building division, which supervises the construction of projects and keeps in touch and directs the constructing forces in the field from the Washington office and through its various supervisors; (2) engineering division, which is charged with the responsibility of the preparation of plans and estimates, and establishes and lays down the fundamental engineering principles, standards and requirements for the work; (3) contracts division, which deals with the preparation and execution of contracts and other legal matters connected with the work; (4) procurement division, charged with the mobilization and procurement of materials and the inspection of these, where necessary, at the source; (5) administrative division, charged with the keeping of necessary records, both in regard to labor and personnel, clerical routine, files and similar work; (6) accounting division, in charge of the accounts and expenditures on the projects, the examination of the field records and accounts; (7) maintenance and repair division, or, more popularly, the operation and maintenance division, which has charge of all main-

tenance as well as the operation of utilities of military posts and camps, and also the operation of similar units at all the projects handled through the Construction Division.

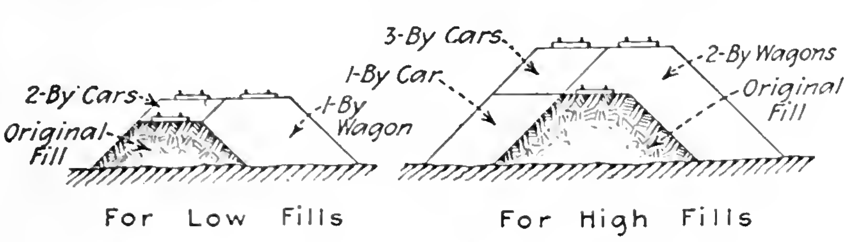
The building and the maintenance and repair divisions control the field work; an understanding of the activities of these divisions will, therefore, involve a complete understanding of the whole construction machine. Further comment will be made later on these two subdivisions, more particularly the maintenance and repair division, with the organization and work of which the writer has been familiar during the past year.

Dump Cars and Wagons Enlarge Railway Fills

Lack of Timber Excludes Use of Trestles for Filling—Work Trains Operate on Main Line—Sinkholes Cause Trouble

IN WIDENING and raising fills for double-tracking and grade reduction on the Cleveland-Indianapolis division of the Cleveland, Cincinnati, Chicago & St. Louis Ry., in 1918, practically all the material was borrowed, there being few cuts because this part of the line traverses an elevated plateau. The borrow pits were mainly shallow and wide, because the general ground level is flat and the drainage is poor. Yellow clay, the principal material in these pits, was hard to excavate, but would slack after exposure. Beneath this was a stiff blue clay affording good foundation for structures. Shrinkage allowance in the fills was about 5% with scraper and dump-wagon work, and usually 10% for the large fills made by dump cars, although in the latter case it was sometimes increased to 20% for soft material.

Earthwork was handled in various ways, depending upon the quantity at each location. Light fills were made mainly by slip scrapers and leveled with road graders handled by teams. Some large fills were made by slip



TWO METHODS OF RAISING AND WIDENING FILLS

and wheeled scrapers, because the subcontractors had this type of equipment. Elevating graders and dump wagons were employed also on large fills, one contractor using teams, and another using steam traction engines, to haul the graders. Most of the heavy work, however, was done with steam shovels served by 12-yd. dump cars in 10-car trains which were operated on the main line by the contractor's 47-ton engines. These cars were dumped by hand, the material being leveled by a large spreader car propelled by a 60-ton locomotive furnished by the railway, as the contractor's engines were too light for this service.

In raising the grade on the old alignment by means of dump wagons, if the fill was comparatively low a side fill was first made alongside the existing work up to the limits of the final section, as shown by the drawing. When this had settled the new construction track was placed upon it, and the fill was widened and brought to grade by dumping from cars on this track.

With high fills, however, the old fill was first widened by dump wagons. With the running track detoured, the second step was to widen the old fill on the opposite side and bring it up to the new grade, by dump wagons. The third step was to widen the new fill by dump cars, bringing the first part of this fill up to final grade. Dumping from temporary trestles was the method planned originally for making the heavy fills, but as the necessary timber could not be obtained the methods described had to be adopted.

When time had been allowed for the fills to settle, the roadbed was graded and finished, and the track was laid on this subgrade, the rails and ties being distributed from the running track. Gravel trains with center-dump cars ran over the new track and deposited the ballast, the track being then raised by jacks and the ballast shoveled under the ties. A second layer of gravel was deposited in the same way and leveled by a plow on the rear car, after which the track was dressed to final surface and line. All the work trains operated entirely under flag protection and not on train orders, being required to keep clear of regular trains.

Trouble With Sink Holes

Three sink-holes caused trouble with the side-dump fills east of Union City. Soundings taken by the valuation engineers of the Interstate Commerce Commission in 1917 showed layers of cinders and gravel ballast extending to a depth of 38 ft., but no soundings have found the bottom of the wet, black, peaty muck of the sinkholes. As the filling was deposited along the old bank the black soil would rise in a ridge beyond it, sometimes to a height of 10 or 15 ft. above the normal level of the ground. Further movement developed also at a distance of 200 to 300 ft. from the fill. The settlement did not appear to affect the old bank, except that the latter was sometimes shifted out of line, and new material had to be placed on the rear side to hold it in position. The new fill, however, would drop 5 or 10 ft. over night, slipping down the slope of the old bank. Raising the dump-car track on a rough clay fill, after such a drop, was slow and tedious. It was expected that from 20,000 to 50,000 cu.yd. in excess of the original estimate would be required in each case, or about 100% increase in quantity. These sinkholes delayed the work somewhat, as the running track could not be shifted to the new fill, but it was planned to discontinue dumping clay and use cinders, until a stable fill was secured.

The concrete materials were distributed by the railway, which hauled sand, stone and gravel in its own 20-yd. air-operated side-dump steel cars, thus avoiding the use of gondolas or other regular freight cars and also permitting rapid dumping and clearing of main track without interference with train movements. The structures were mainly concrete boxes and culverts of cast-iron and concrete pipe, with a few short girder spans. The old National Turnpike crosses at one of the sinkholes, and will be carried by a reinforced-concrete undercrossing or subway 24 x 14 ft. formed as a massive monolithic structure. Pile foundations will

be provided, using 40-ft. piles and following these with others if they do not reach solid ground.

The Walsh Construction Co., Davenport, Iowa, had the general contract and did all steam-shovel and dump-car work with its own forces, under E. K. Hayes and W. I. Shillito as superintendents. Subcontracts were let for scraper and dump-wagon work, and all concrete work was sublet to the Cleary-White Construction Co., Chicago. Both native and foreign laborers were employed by the Walsh Co., with separate accommodations at the camps, as the foreigners prefer to do their own cooking. These men were mainly Bulgarians, Austrians, Greeks and Macedonians, but they worked together without much trouble. The pay for common labor was $4 per eight-hour day.

The work was under the direction of C. A. Paquette, chief engineer of the Cleveland, Cincinnati, Chicago & St. Louis Ry. W. C. Kegler was district engineer, with F. N. Johnson as resident engineer on the section from Marion to Bellefontaine, and T. E. Earle as resident engineer from Ansonia to Winchester.

Successful Operation of the State Water Code of Oregon

Shows a Saving in Time and Water to Irrigator—Function of State Water Board, State Engineer and Water Master

By Percy A. Cupper
State Engineer, Salem, Ore

Since a number of Western states propose to enact or amend water codes during the present legislative session, a review of the Oregon code and operations under it may be of value, especially as it is generally conceded that this is the most successful code now in force.

Viewed from ten years of successful operation of the Oregon water code, it is difficult to understand why its enactment was so long delayed. In fact, it now seems strange that when provision was originally made for a definite record of land titles, no such provision was made for a definite record of water-right titles. When our constitutions were framed and early laws enacted, the fact that water for irrigation was worth more than the land itself was not generally recognized.

The result of our inadequate water-right records, or their total lack, is clearly seen in the way the courts have been compelled to decree imaginary water rights, or rather imaginary water. The courts cannot be held responsible for the lavish manner in which they bestowed water upon one of two litigants in a proceeding notwithstanding the fact that a large part of the available supply was covered by prior appropriations. Definite information as to the available supply and the amount covered by prior appropriations or the amount necessary for the needs of the litigants has in most cases been conspicuous by its absence. It is no wonder, then, that years of litigation between various water users on a stream has resulted in hopeless confusion of rights, while each new appropriation adds to the confusion.

The Oregon Water Code performs three distinct functions:, (1) The determination of all existing rights; (2) the definite record of new appropriations, and (3) the distribution of water to the water users in accordance with their respective rights.

In Oregon the determination of water rights is made by the State Water Board, consisting of the State Engineer and the superintendents of the two water divisions into which the state is divided. The State Engineer is required under the statute to secure certain physical data relative to the amount of water available in the stream under adjudication, the amount actually applied to the lands or other use, and the capacity of the various ditches. In addition, he is required to prepare a map showing the number of acres in each 40-acre tract that are irrigated. Too much emphasis cannot be laid upon the necessity of securing accurate and reliable data under this provision of the statute. Experience has shown that obtaining accurate and reliable data during a period covering one or two irrigation seasons, making a complete analysis of the same and presenting the results obtained in the form of a report embodying definite recommendations, will not only serve as a basis for the findings of the board, but will eliminate the taking of many hundred of pages of testimony, and, if fairly and impartially performed, will generally be acceptable to the water users.

The formality of court proceedings is eliminated in so far as practicable. The water users are permitted to come in and file their claims, and, in fact, are assisted in preparing the same if they so desire. In other words, those in charge of the adjudication work with the water users in an effort to have the claims presented so as to represent the actual conditions. The maps prepared by the State Engineer are available at the hearings, and the claims are checked with the map. If they do not correspond, arrangements are made to make further investigations and adjust the discrepancies. If claims are filed to which other claimants have objections, an opportunity is afforded to contest them, and testimony may be offered before the superintendent.

It may be added here that in these water-right determinations an effort is always made to conform the findings of the board to the general practice of irrigation on the stream, providing such practice does not involve a wasteful use of water to the extent that it cannot be justified as a beneficial use.

It may be said, therefore, that primarily the advantage of a water-right determination by the State Water Board lies in the fact that it may on its own initiative obtain any and all information which may be necessary or desirable in arriving at a determination of the relative rights of the respective water users on a stream or stream system. It determines all of these rights at one and the same proceeding, and therefore, has an opportunity of considering the relation of the various rights to each other.

Water-Right Certificate and Follow-Up System

It would be of little value to determine all existing rights if every new right that was initiated injected an element of uncertainty into the water-right situation, thus creating dissensions and opening the way for litigation. The Oregon water code provides for the initiation of water rights by the filing of applications in the office of the State Engineer and obtaining a permit thereon. Upon satisfactory proof that the water has been completely applied to the proposed use, a water-

right certificate is issued, as in the case of water rights which have been adjudicated by the state water board. However, it is obvious that if, after a permit was issued no further steps were taken to determine what progress was being made and the state engineer's office simply awaited the submission of final proof, it would soon be impossible to determine whether or not many of the permits were in good standing. For this reason a follow-up system has been adopted in Oregon whereby each permit holder files a report each year on a form attached to the permit, and in case no such report is filed he is notified by post card.

Double Purpose of Follow-Up System

This follow-up system serves a double purpose:

1. It keeps the records in the office of the State Engineer up to date, and an examination of these records indicates which permits are in good standing, and this in turn is of value in determining the amount of available water which may be appropriated by those desiring to initiate subsequent development. Without this follow-up system the records of water rights would soon be in the same chaotic condition that characterized water-right records prior to the enactment of the water code. That is to say, the records would merely show the filings that had from time to time been made, and would not indicate whether or not the rights had been perfected or were in good standing.

2. The follow-up system prevents the permittee from inadvertently allowing his rights to lapse through failure to begin the work within the time specified in the permit, or to prosecute the same with reasonable diligence, as required by the statute.

It is the duty of the administrative office having charge of the development of our water resources to assist in every practical way those who are endeavoring through their own efforts and expenditure of capital to develop these resources. It is the duty of those officials, and the water code offers to them a wide opportunity to work with those engaged in this line of development. Particularly is this applicable to the man who is endeavoring to irrigate his own holdings, which are generally small. It is in this that the follow-up system, by which the State Engineer's office keeps in touch with the status of permits, is of real service to the appropriator.

There is a marked distinction between a water right and water. It is essential that an adequate record of water titles be maintained, but it is also essential that the water users actually receive the water to which each is entitled. No water code would be complete unless it provided the necessary machinery for the actual delivery of water to those entitled to its use. The past history of irrigation has repeatedly shown that a man may have a prior right to the use of the water of a stream and yet be unable to secure water for the irrigation of his land, notwithstanding the fact that subsequent appropriators had an adequate supply. Injunctions sometimes have afforded the necessary relief, but are totally inadequate in cases where the distribution of the waters of a large stream is complicated by many diversions and users of water.

The Oregon water code provides for the appointment of a water master with full authority to distribute the water in accordance with the findings of the board or the decree of the court. The water master is allowed considerable discretion, however, in preventing the wasteful use of water. When the flow of a stream is not sufficient to reach a prior appropriator far down the stream, or it requires an excessive amount of water to provide him with that to which he is entitled, the water master either permits a subsequent appropriator higher up the stream to use the water or installs a rotation system whereby the entire flow of the stream is turned down for a short period of time to the prior appropriator, thereby eliminating much of the waste which would otherwise occur. By the use of discretion and diplomacy the water master is not infrequently able to make what would otherwise be an inadequate supply serve the entire district.

Irrigator's Time and Water Both Saved

It is a well known fact that much of the irrigator's time in the past has been taken up with a vain endeavor to prevent his neighbor from destroying his dam and taking the water to which he was, or thought he was, entitled. In fact, that has been a serious hindrance in many irrigation communities, and has led to much litigation and even to bloodshed. Not alone is the irrigator saved the time that it requires to protect and repair his dam and headworks, but also much time is saved by the distribution of water by rotation, which the water master encourages wherever practicable. It was very difficult indeed under the old plan for two or three neighbors to coöperate to the extent of using the water in turn, thereby irrigating their land in much less time and at much less expense. This was not due entirely to the inability of the neighbors to coöperate, but was due to a large extent to the fact that each water user felt that he would jeopardize his legal right to the use of the water unless it was used continuously throughout the irrigation season. This fear of legal complications is entirely eliminated under the Oregon water code, and it is an easy matter to show the water user the advantage he will gain by using the water by rotation.

It may be said, therefore, that distribution of water under the direction of a water master saves time, water and litigation.

At the time of the enactment of the Oregon water code considerable objection was encountered from large interests which apparently felt that their rights would be jeopardized by the state's supervision over its water resources. However, it now appears that this objection has entirely disappeared, and practically all water users find that through the administration of the water code they receive a real benefit.

The Oregon water code has served as a model for similar statutes in a number of our Western states. It is the only statute of the kind that has been passed upon and upheld by the Supreme Court of the United States.

I believe the Oregon water code and the irrigation district law are the two greatest assets which Oregon has in its irrigation development. The irrigation district law has placed irrigation as an enterprise on a sound business basis; this has been demonstrated by the results which have been obtained since its enactment. The water code makes it possible for a man with a water right to determine the exact nature and extent of that right, to record the same, and to secure actually the water to which he is entitled.

Shipping Board Protects Health of Shipyard Men

Sanitary Engineers Control Water and Food Supply, Housing, Sewerage and Garbage—Abate Flies and Mosquitoes

RECOGNITION of the health and contentment of workmen in the shipyards as a factor in the rapid output of vessels led the United States Shipping Board to create a department of health and sanitation, which was placed under an officer who received a free hand in carrying on the work as he saw fit. In a paper presented before the sanitary engineering section of the American Public Health Association, at its recent meeting in Chicago, this special work was reviewed by Lieut. Col. Philip S. Doane, director of the department.

A fundamental difficulty was encountered in the fact that shipyard employees are not under direct control, like soldiers and sailors, and are not obliged to carry out orders, while shipyard managements were so fearful of losing men that they would not issue orders likely to be objectionable to the men. Furthermore, while sanitary measures could be carried out without much trouble in the 11 yards operated by the board, the condition was very different in the other 160 yards working under contracts. None of these contracts calls for specific sanitary equipment, and only a few call for maintenance of sanitary and hygienic conditions. The shipyard health department, therefore, had to use diplomacy and to act largely in an advisory capacity, but Colonel Doane pointed out that in very few instances have the shipyards failed to follow out suggestions for improvements.

Sanitary engineers and medical officers were civilians, as no Army officials could be spared, and the major part of the work fell upon the engineers. To improve water-supplies, toilets and sewerage and other sanitary facilities, it has been necessary to have men constantly on the ground to assist and advise the engineers of the yards. As most of the yard employees live in neighboring cities and towns, the shipyard health department has endeavored to protect their home environment, with the assistance of local and state health authorities. Insanitary restaurants outside the yards have been condemned and replaced by restaurants conducted in a sanitary manner under the supervision of the local health officials.

Water-supply received special attention. Colonel Doane states that a thirsty man will drink, regardless of signs or instructions, "any water that is wet." Therefore, the policy adopted was that only pure drinking water should be supplied for washing and that outlets from industrial or fire protection mains should be of such type as to make it impractical or inconvenient to drink from them.

The importance of fire protection makes a dual system of mains the usual practice, and these were frequently connected, the only protection to the drinking water mains being a single gate valve. These connections have been mainly eliminated, and those absolutely necessary have two check valves with devices for frequent testing. Drinking water was at first distributed by buckets and common drinking cups, but the department has succeeded in having bubbler fountains installed in many yards.

Lavatories have been a source of much controversy. Methods of disposal of excreta and sewage are many in the average shipyard, owing to the waterside location, and the department's recommendations depended largely upon the character of the waterway at each yard. Care has been taken to secure collection of garbage in closed containers and its proper disposal. The collection and disposal of manure, and keeping the yards clear of refuse matter, have been included in the work.

Mosquito elimination was an important branch of the work, as the yards are often in proximity to swampy areas and the men must work in night shifts. The swamps have been drained and oiled. Flies were recognized as carriers of disease, and were trapped and destroyed, while measures were taken to control their breeding places. Eradication of vermin in barracks and living quarters introduced some problems, and at certain yards methods were adopted to solve them.

No public health officers was maintained by the City of Bath, Me., where there were two shipyards, and it was found that impure milk and meats were being delivered there. The city had no funds for such an official, but agreed to give all necessary authority if the department would pay the salary. A sanitary engineer, therefore, has acted as health officer for six months. He has secured pure milk and food supplies and has also improved general sanitary conditions.

The care of the thousands of men engaged in the construction of the barracks, hotels and houses for the shipyard employees has been another special branch of work. At Wyandotte about a thousand men were made ill by drinking water from the Detroit River, which Colonel Doane calls "diluted sewage." A temporary disinfecting plant was installed and a campaign was conducted to get the inhabitants to vote a bond issue for filters. This has been carried, although local opposition at first made this seem impossible.

The protection of the sailors also comes under the direction of the health department, which will supply each vessel with medicine chests and first-aid equipment. In the classes of instruction there will be a course on the use of this equipment. Colonel Doane's paper expressed high appreciation of the efficiency of the sanitary engineers' work.

Sewage-Treatment Project for Calumet District

A sanitary drainage district in the Calumet region of Indiana, to embrace the four industrial cities of Gary, Hammond, Whiting and East Chicago, having a combined population of about 150,000 is proposed. The sewage of these towns is now discharged through the Calumet River into Lake Michigan. The plan is to treat the sewage and reserve the flow so it will pass through the new Sag channel to the Chicago Drainage Canal. The sewage-collecting system of each city would remain under local control, but would deliver the sewage to a central or joint plant for treatment before its discharge into the river. No definite plans or estimates have been made and enabling state legislation will be required. C. B. Tinkham, Hammond, Ind., is head of a joint legal commission representing the four cities.

Comparison of Various Existing and Proposed License Laws

Form Suggested by Joint Committee of National Societies in 1915 Used as a Basis in Several States. Many Societies Are Working on Legislation

ENGINEERING societies in several states—Ohio, Minnesota, Wyoming, Iowa, Kentucky—have legislative committees at work on the preparation of engineers' license laws, and the subject is so important that various existing and proposed laws have been examined with the object of bringing together the principal features, for purposes of comparison. The states which now have laws regulating the practice of engineering or of surveying are Wyoming, Louisiana, California, Illinois, South Dakota, Idaho and Florida. Of the many states where licensing has been proposed, or where new laws are being advocated, those here considered are Pennsylvania, Indiana, California, Colorado, and Michigan.

The significant features of these bills are here given for comparison with the corresponding provisions in the suggested standard form of law to license all classes of engineers, as proposed in 1915 by a joint committee of the American Society of Civil Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Institute of Mining Engineers, the Society of Naval Architects and Marine Engineers and the American Institute of Consulting Engineers. None of these societies, however, has given its official sanction to the committee bill, which in turn was modeled after a proposed bill written by a committee of the American Society of Civil Engineers in 1911.

The features which are here considered, in order, are: 1, Definitions, and scope of bills; 2, enabling clauses for permission to practice; 3, boards of engineering examiners; 4, qualifications of candidates, notice of examinations; 5, total fees for certificates, granting certificates without examination; 6, revocation and reinstatement, and 7, penalties, exemptions from application.

Definitions and Scope of Bills

1. The various laws differ in defining the practice of engineering and in their scope, as follows:

Joint Committee, Proposed 1915—A person practices professional engineering who practices any branch of the profession other than military engineering, including the design and supervision of construction of: Public and private utilities such as railroads, bridges, highways, roads, canals, harbors, river improvements, lighthouses, wet docks, dry docks, ships, barges, dredges, cranes, floating docks and other floating property; steam engines, turbines, internal combustion engines and other mechanical structures; electrical machinery and apparatus, and works for the development and transmission or application of power; mining operations, processes and apparatus for carrying out such operations; municipal, irrigation, water-supply, sewerage, drainage, industrial, sanitary, hydraulic and structural works, and other public or private utilities or works which require such experience and technical knowledge as are required for admission to examination. It provides that this enumeration shall not be exclusive, and exempts contractors as follows:

"The execution as a contractor of work designed by a professional engineer, or the supervision of the construction of such work as a foreman or superintendent for such contractor, shall not be deemed to be the practice of professional engineering."

Wyoming, Passed 1907—Limited to engineers and surveyors who perform any field work preliminary to the preparation of an application for permits to use the water of the state, or who shall make surveys or do engineering work relative to the utilization or use of water.

Louisiana, Passed 1908, Amended 1914—Applies to civil engineers and surveyors only.

California, Passed 1909—Requires all county surveyors, or candidates for that office, to be licensed land surveyors.

Illinois, Passed 1915—Provides for licensing of structural engineers and was intended to relieve the disability which the Illinois law for licensing architects imposed upon them. Any person engaged in the designing or supervising of the construction, enlargement or alteration of any structures, other than buildings, or any part thereof, for others, and to be constructed by persons other than himself, shall be regarded as practicing structural engineering. By structures is meant all structures, other than buildings, having as essential features foundations, columns, girders, trusses, arches, and beams, with or without other parts, and in which safe design and construction require that loads and stresses must be computed and the size and strength of parts determined by mathematical calculation based upon scientific principles and engineering data. Certain structures designed solely for given engineering purposes, even though they may be buildings as defined in the act for licensing architects, are included in the term structures as defined. But it is stated that the act shall not "prevent any person, mechanic, or builder from making plans or specifications, or supervising the construction, enlargement, or alteration of any structure or building which is to be constructed by himself or his employees, and for his own use."

South Dakota, Passed 1913—Provides that county surveyors must be licensed, and that no survey is legal except when made by a licensed surveyor.

Idaho, Passed 1915—Licenses surveyors, and provides that no survey of land, plat or subdivision shall be legal unless made by a licensed surveyor.

Florida, Passed 1917—The definition of professional engineer in this law, which took effect Jan. 1, 1918, follows verbatim the Joint Committee bill, but it exempts persons acting as public officers for the state, county, or municipality on work where the estimated cost is $1000 or less. In all other provisions, except as noted

hereafter, this act duplicates the Joint Committee bill. Of the foregoing laws, the Florida act alone applies to all classes of engineers, while of the following proposed laws those for Pennsylvania, Colorado and California would include all engineers. Two states, Indiana and Michigan, have proposed bills to license architects and engineers under the same act.

Pennsylvania, Proposed 1914—This act was developed in preliminary form by a commission, appointed by the Governor of Pennsylvania, consisting of four members of the American Society of Civil Engineers and one member of the American Society of Mechanical Engineers. The introduction states the object to be: "To protect safety, life, health, and property by regulating the surveying, the designing, the supervision of construction, the operation and the maintenance of certain public and private works herein defined, providing a method of enforcing this act and providing penalties." The term "professional engineer" is defined to mean any person who practices professional engineering or any branch other than military engineering, including the designing or general supervision of construction or of the operation and maintenance of public or private works, such as railroads, railways, bridges, highways, canals, harbors, improvements to rivers and other streams, lighthouses, docks of all kinds, vessels of all kinds, dredges, cranes; also of appliances for the generation of power by stream, combustion, or electricity, or works for the development, transmission, or application of power; the design or general supervision of mining operations, or of the appliances, machinery, and apparatus connected therewith; also of municipal works of all kinds, the impounding and distribution of water for any purpose, sewerage, drainage, industrial, sanitary, hydraulic or structural works. The board shall determine from time to time what other branches shall be included in the foregoing enumerations.

Indiana, Proposed 1918 — Licenses architects and structural engineers, to include any person engaged in the planning, designing, or supervision of the erection, enlargement, or alteration of buildings or structures, or any part thereof for others, and to be constructed by persons other than himself. But draftsmen, students, clerks, or superintendents and other employees of those lawfully practicing as architects or structural engineers under licenses, are exempted. A similar provision to that in the Illinois law is made to exempt owners who build their own structures.

California, Proposed 1919—The definitions in this act, which has just been introduced into the state legislature, follow the Joint Committee very closely. It adds that the practice of professional engineering involves the control of forces of nature and the utilization of materials and these forces for the the benefit of man, and that certificates of practice will permit the holder to offer his services in consultation, in investigations, and for research work. It also adds telegraph and telephone systems and plants for the distribution of steam, water, gas, and other elements, and for heating and ventilating, to the list of mechanical structures. It includes the examination of mining properties and supervision of mining and metallurgical operations, and those of the oil industry. The execution as a contractor is exempted as in the case of the Joint Committee law.

Colorado, Proposed 1918-1919—Would define an engineer, without specific details, as a person who is engaged in the practice of the profession of engineering in any of its branches, except military engineering.

Michigan, Proposed 1919—Two bills have just been introduced into the legislature:

1. For the certification of engineers engaged as principals in "the design and erection of structural work for buildings and bridges; the measurement of streams; the location, design, and supervision of construction and maintenance of dams, river and harbor improvements; highways, railways, navigation canals, drainage and irrigation works, garbage-disposal plants, public sanitary systems, public water-works and municipal paving; and the making of surveys relating to property, political and geographical boundaries."

2. The other act provides for the registration of architects and engineers, although any person who has been qualified to use the title "registered architect" under the existing act may continue to use such title until Jan. 1, 1921.

Permission to Practice

2. The enabling clauses for permission to practice vary as follows:

Joint Committee—No person shall practice professional engineering without having first been duly and regularly registered, nor shall any person be permitted to testify or be accepted as qualified as an expert witness in professional engineering matters, unless duly registered; and every map, plan and drawing required by law to be certified or approved by a professional engineer shall be so certified by a regularly registered engineer.

Wyoming—This law, which is limited to engineers and surveyors having to do with the use of water, as above mentioned, requires that candidates must belong to one or more of the following classes: (1) Land surveyors, (2) topographic engineers, (3) hydraulic and hydrographic engineers, (4) construction and designing engineers, (5) administrative irrigation engineers.

Louisiana—Provides that any person, before entering the practice of civil engineering or surveying, must present to the Board of Engineering Examiners a diploma from an engineering college or school of good standing, such standing to be determined by the board, or shall pass a satisfactory examination before the board. Certificates must be recorded in the office of the clerk of the district court of the parish in which the applicant resides.

California—Three methods of licensing are contained in this law: By examination; by recommendation of three licensed surveyors; by the possession of a diploma from almost any technical school, the Board of Examiners being the judges as to the reputability of the school.

Illinois—After six months from the taking effect of the act, it shall be unlawful to practice structural engineering in the state without a license or to advertise or display a card or sign therefor.

South Dakota—According to this law no survey is legal except that made by a licensed surveyor.

Idaho—No survey of land, or plat or subdivision shall be legal unless made by a licensed surveyor, and all

surveys made under the authority of the state, or any county, town, city or village within the state, must be performed by a local surveyor. If the result of the examination of any applicant is satisfactory to a majority of the Board of Examiners, the applicant receives a license to practice structural engineering in the state, this license containing the full name, birthplace and age of the licensee.

The proposed laws which contain enabling provisions are:

California—After July 1, 1920, no person shall practice professional engineering without having first been duly and regularly registered.

Michigan—The first bill provides that after Oct. 1, 1919, before engaging as principal in any one or more of the branches of engineering specified, an applicant must qualify by examination in one or more of these specified branches, and the board shall certify all engineers qualifying under this section; the other bill provides that no person shall use the title "registered architect" or "registered engineer," or any variation of the same, or use any word, letter or device to indicate that the person using same is so registered, after 90 days subsequent to the passage of the act, without being registered in accordance therewith. Certificates shall indicate the character of work for which the registrant is qualified.

State Board of Engineering Examiners

3. Nearly all the bills provide for a board of examiners, generally either of nine or five members, as follows:

Joint Committee—A State Board of Engineering Examiners shall consist of nine members, to be appointed by the Governor, the first appointments to be made at three regular intervals, as specified, the regular term of office thereafter to be six years. The Governor may remove any member for misconduct, incapacity or neglect of duty. Each member shall be a professional engineer of at least 10 years' active experience and recognized standing in his profession, shall be at least 35 years old, and shall have been a resident of the state for at least one year immediately preceding his appointment. Except the first appointees, each member shall also be a registered professional engineer.

The members shall serve without compensation except for traveling and other necessary expenses. The board is entitled to the services of the Attorney General, and can compel the attendance of witnesses, and may take testimony and proofs pertaining to all matters within its jurisdiction. The board shall appoint a secretary, not a member of the board, but who shall possess the qualifications required for members thereof. The secretary shall hold office during the pleasure of the board and receive a specified annual compensation. The board shall hold at least six stated meetings each year, and special meetings as its bylaws may provide. At meetings held solely for the examination of candidates for registration, three members shall constitute a quorum. At all other meetings, a majority shall constitute a quorum. The board shall have power to employ clerks and other employees, and to rent offices as may be necessary to the proper performance of its duties.

The Board of Examining Engineers in Wyoming consists of the State Engineer and two engineers of thorough training and experience, appointed by the Governor and serving without compensation.

Louisiana—The Board of Engineering Examiners consistes of five members, three of whom shall constitute a quorum, all required to be practicing civil engineers or surveyors in good standing. Members are appointed by the Governor for a term of six years, from a list presented by the Louisiana Engineering Society; the Governor has the right to remove any or all members for inefficiency or neglect of duty, and to fill the vacancies occurring in the board from names recommended by the same society.

Illinois—The State Board of Examiners of Structural Engineers is composed of five members, one a professor in the civil engineering department of the University of Illinois, and the others structural engineers of recognized standing, of not less than 10 years' practical experience, and practicing as structural engineers in Illinois. The regular term of office is four years, and candidates are appointed by the Governor. A secretary receives a salary fixed by the board, not to exceed $1,500 per annum, together with traveling and other expenses. The members of the board receive the sum of $10 for each day actually engaged in the performance of their duties, together with legitimate expenses. Three members constitute a quorum. The board's rules and regulations for the examination of applicants must be published at least twice in one engineering journal of general circulation in the state, and one daily newspaper, together with the name and address of each officer. At least two examinations are held each year.

South Dakota and Idaho—Applications for licenses are made to the State Engineer, who alone has power to grant licenses to practice land surveying.

Florida—The State Board of Engineering Examiners consists of five members appointed by the Governor, three of whom are civil engineers, one a mining or electrical engineer, and the other a mechanical engineer or naval officer. The regular term of office is four years, and the Governor may remove any member for misconduct, incapacity or neglect of duty. Each member of the board must be a professional engineer of at least 10 years' active experience, of recognized good standing in the profession, at least 35 years of age, and have been a resident in the state for three years immediately preceding his appointment. Each member must be registered as a professional engineer, and be also a member in good standing of a recognized engineering society.

Members serve without compensation, except traveling and other necessary expenses. The board is required to hold at least two regular meetings each year and has power to employ clerks and other employees and rent offices, as may be necessary, for the proper performance of its duties.

The proposed bills provide for examining boards as follows:

Pennsylvania—The State Board of Examining Engineers would consist of nine members appointed by the Governor, each member serving for a term of six years except those first appointed, of whom three shall be appointed for two years, three for four years, and three for six years. Each member of the board shall be a professional engineer of at least 10 years' active experience, and have the qualifications demanded of the

highest grade membership in one of the four national engineering societies, and must be at least 35 years of age, having been a resident of Pennsylvania at least five years immediately preceding his appointment. After the first appointees, the members must be registered professional engineers.

They shall serve without compensation, except expenses actually incurred in the performance of duty. The secretary is a member of the board, he is appointed by it and holds office during the pleasure of the board, and shall receive an annual compensation of $3600. The board shall hold at least six stated meetings annually in Harrisburg, five members to constitute a quorum.

Indiana—The State Board of Examiners of Architects and Structural Engineers would be composed of five members, not more than three of whom shall be of one political party, two shall be architects and two shall be structural engineers, and one shall be neither an architect nor a structural engineer. All shall be residents of Indiana, in good standing, and the professional members shall have been engaged in independent practice for at least five years. The regular term of office shall be five years. Appointments are to be made from a recommended list of five architects and five structural engineers from the Indiana Society of Architects and the Indiana Engineering Society, respectively, except the member who is neither an architect nor a structural engineer. Regular meetings shall be held in January, April, July and October of each year; three members shall constitute a quorum. The board is to adopt rules and regulations for examinations and publish the same in one daily newspaper in Indiana at least twice. Examinations shall be held at least twice each year.

California—Provides a State Board of Engineering Examiners in accordance with the Joint Committee bill, the first appointments to be made for two, four and six years.

Colorado—The Governor appoints a State Board of Engineer Examiners, composed of five members, legal residents of the state, who have been engaged in the practice of engineering at least 10 years. The State Engineer is ex officio the fifth member of the board Members of the first board receive a certificate of appointment to entitle them to a license. Successors are appointed for a term of four years from a list of five nominees elected by the licensed engineers acting in a general assembly called for this purpose in January next preceding the expiration of the terms of any members. The State Engineer acts as secretary and treasurer.

Members shall serve without compensation other than necessary expenses, to be paid from the special "Engineer Examiners' Fund" obtained by the fees derived from the operation of the act.

Michigan—(1) The board shall consist of three representative engineers who have been residents of the state not less than five years and engaged in one or more of the specified branches of engineering not less than 10 years. After Oct. 1, 1919, only registered engineers are eligible. The Governor shall appoint one member from the upper peninsula, one from that portion of the southern peninsula lying north of the Michigan base line and one from that portion of the state lying south of the Michigan base line. The terms of office shall be six years. Members are to receive $25 per day, with expenses. (2) The other bill provides that the Governor shall appoint a board of five examiners, composed of two architects and three engineers, who have been in active practice of their professions as principals for not less than 10 years, and who are otherwise qualified, one of them to be from the upper peninsula. Not more than one engineering member shall belong to any one of the five major classes of engineers—civil, mining, mechanical, electrical, and chemical. No person shall be appointed except upon the indorsement of not less than 25 practitioners of recognized standing in the profession he is to represent. The regular term of office is five years. Meetings are to be held twice each year. Members of the board receive no compensation, except actual expenses.

Qualifications of Candidates—Examinations

4. In specifying the qualifications of candidates and providing for examinations, the various acts require:

Joint Committee—Admission to examination is allowed to any candidate who pays a fee of a sum to be specified and submits evidence satisfactory to the board that he is more than 21 years of age, is of good character, and has been engaged upon engineering work for at least six years, during which period he has had charge as principal or assistant for at least one year; or that he is a graduate from an engineering school of recognized reputation and has been engaged upon engineering work for at least four years, having had charge as principal or assistant for one year. Scope of examinations and methods of procedure shall be prescribed by the board; examinations may be either oral or written, or partly oral and partly written. The secretary of the board shall notify each candidate of the result of his examination.

Wyoming—The board may satisfy itself by conducting examinations or by investigation of the records, training and experience of those who desire to qualify. The moral character of the applicant is investigated, and no license is issued to one who is incompetent, dishonest, intemperate or addicted to any habit that would, in the judgment of the board, render him an unsafe employee.

Louisiana—A satisfactory examination, for which a fee of $10 is required, shall be passed upon the following: For surveying—geometry, trigonometry, land surveying, practical use of instruments; for civil engineering—the same as for surveying, and in addition thereto, natural philosophy or physics, including practical problems in design and construction. The applicant must be 21 years of age, of good moral character, and possess at least a fair primary education.

South Dakota—Requires a $15 fee to become a candidate, $5 to be returned if the candidate fails to pass the examination. Any practicing surveyor of 10 years' experience, with testimonials satisfactory to the State Surveyor, receives a certificate without examination.

Idaho—The application shall be referred to a member of the Board of Examining Surveyors, who will make such examination as to the applicant's fitness for license as he may deem necessary, certify the result to the State Engineer, and the latter will then notify the applicant.

Illinois—Examinations shall be held according to rules of the board, a majority constituting a quorum, or by a committee of two or more members elected and appointed by the board. These examinations are conducted by written or printed interrogatories, in whole or in part, and each applicant must sustain "a satisfactory examination in the design and construction of buildings and structures according to scientific principles and with special reference to strength and safety; the strength and properties of various building materials; the principles of theoretical and applied mechanics; the ability of the applicant to apply his knowledge to ordinary requirements of structural engineering, and in such other matters and subjects as the board may require."

A fee of $20 is required of the applicant, who must submit proof, by affidavit or otherwise, that (a) at the time of taking effect of the act he was actually engaged in the practice of structural engineering in the state and did not apply for a license without examination, in which case the applicant shall be entitled to an examination without regard to the number of years he has practiced; or (b) that within 10 years next prior to his application he has practiced structural engineering in some state or territory of the United States or some foreign country for not less than six years, during at least two full years of which he shall have been in responsible charge of work as principal or assistant; or (c) that within 10 years next prior to his application he has pursued a course of study and training in the theory and practice of structural engineering covering at least the subjects above enumerated, for a period of not less than six years in the employ or under the supervision of practicing structural engineers, during at least two years of which he has been in charge of work in designing or construction, in the employ or under the direction of such engineers. Graduation from a school or college of engineering considered to be in good standing by the board, having a course of study not less than four years, during at least thirty weeks each year, shall be credited two years upon the six-year period. The board may adopt rules in its discretion for the case of students who have pursued the course of instruction but were not graduated from schools or colleges of approved standing.

Provisions for qualifications of candidates and examinations in proposed bills are as follows:

Pennsylvania—Qualifications for applicants are prescribed similar to those in the Joint Committee bill.

Indiana—Any person of good moral character over 21 years of age, upon payment of a fee of $20, shall be entitled to an examination. Examinations for architects shall have special reference to the planning, designing and construction of buildings or structures, and their sanitation, and include a test of the candidate's knowledge of the strength of materials and their properties, with special reference to their strength and safety, and of his ability to make practical application of such knowledge in the ordinary professional work of an architect, and in the duties of supervisor of mechanical works in a building or structure; also such other subjects as the board may require from time to time. Examinations for structural engineers shall have special reference to design and construction of buildings or structures according to scientific principles as above; the principles of theoretical and applied mechanics; the ability of the applicant to apply his knowledge to ordinary requirements of structural engineering; also other subjects as the board may require.

California—Same as the Joint Committee bill.

Colorado—Examinations shall be given to the candidate only in that branch of engineering in which he is proficient, as set forth in his application. The board has authority to summon any engineer holding a license to assist in preparing for and conducting examinations of candidates, such engineers being remunerated, at not to exceed $10 per day, in addition to necessary expenses. The board admits to examination any candidate who pays a fee of $10, is a citizen of the United States more than 25 years of age, of good moral character, and who has been actively engaged in the practice of engineering at least 10 years in the employ of practicing engineers. Each complete year as a student in an engineering school of recognized reputation shall be credited as one year of practice. During six years he must have been in active responsible charge of engineering work. Responsible charge is held to mean the actual supervision and direction of engineering work requiring the exercise of initiative, judgment and independent decisions, and may be performed in the capacity of either principal or assistant.

Michigan—(1) Applicants for examination must satisfy the board that they have had not less than six years of practical experience in one or more branches of engineering as specified, or shall have been graduated in engineering from a recognized school or college of engineering, and have had in addition not less than two years of practical experience. After Oct. 1, 1919, practical experience means work performed as a subordinate under the supervision of one or more certified engineers; (2) The second bill provides that the board shall adopt rules and regulations for the examination and classification of candidates for registration, and the issuance of certificates thereto. Any person of legal age and good moral character, upon payment of a fee of $10, may apply for examination.

Total Fees—Certificates Without Examination

5. The total fees for certificates, and provisions for licensing upon the passage of the act, and for licensing engineers from other states without examination, are as follows:

Joint Committee—Upon receipt of an additional fee, amount to be specified, the board shall issue to any applicant who has passed the examination a certificate of registration which authorizes the applicant to practice engineering. The board shall examine requirements for registration in other states, territories, and countries, and record those which it believes has standards not lower than those provided for the state. Persons holding certificates of such states are to be registered upon payment of a specified fee.

Provision is made for registration without examination by issue of certificate before a specified date to any candidate who has practiced professional engineering at least 10 years immediately preceding the date of application, and has had charge as principal or assistant for at least two years.

Wyoming—A fee of $5 is required before the issuance

of a license, which license is signed by the president of the board and attested by the secretary under his seal.

Louisiana—Persons practicing civil engineering or surveying in the state before the passage of the act are allowed 90 days to register with the clerk of the court of the district in which they reside. The Board of Examiners must publish annually in February a complete list of registered civil engineers and surveyors in a daily paper of the City of New Orleans, this list being received as evidence in court that the names it contains are duly registered. The annual fee is $3 for civil engineers and $1 for surveyors if paid before Feb. 1, but $10 and $5, respectively, after that date.

Illinois—If the result of the examination is satisfactory, the applicant receives a license to practice structural engineering, upon payment of the further sum of $30. Any person who could show that he was a resident of the state and engaged in the practice of structural engineering on the date of the taking effect of the act, is entitled to a license without examination, provided such application be made within six months after the taking effect of the act, and a fee of $50 be paid. Also, for a fee of $50 the board may issue without examination a license to practice to a structural engineer who has been licensed under the laws of any other state or territory, or foreign country, provided it appear to the board that the requirements in such countries were equal to those prescribed in Illinois, and that such countries would afford a like privilege to structural engineers who hold Illinois licenses. The Secretary of State is to receive a fee of $1 for the recording of each license filed for record. Every licensed structural engineer shall have a seal, the impression of which must contain the name of the engineer, his place of business, and the words "Licensed Structural Engineer—State of Illinois," with which he must stamp all plans, drawings and specifications issued by him for use in the state.

Idaho—License is issued to a successful candidate upon submitting to the State Engineer a $500 bond, $5 fee and official oath. The bond must be a surety company bond. Under the provisions of this statute all persons who are graduates of a course of civil engineering from the University of Idaho may receive a license without examination, upon their own application.

Florida—The additional fee prescribed, as in the Joint Committee bill, is $10. Provision is made for engineers from other states also, as in the Joint Committee bill, the fee being $25. For this same fee, $25, practicing engineers received certificates before Dec. 1, 1917.

The provisions in various proposed laws are:

Indiana—Required, fee of $30 and certificates allowed to be issued to engineers who can show that they were engaged and in good standing in the practice of architecture or structural engineering on the date of the passing of the act, provided such applicant should show that he was in good repute in the practice of his profession. A certificate may also be issued without examination, upon payment of a fee of $50, to an architect or to a structural engineer licensed under the laws of any other state or territory, or of any foreign country, provided it appears to the board that such places have requirements for license equal to those required in Indiana.

California—Certificates of registration are issued upon payment of an additional fee of $20, and the provisions for registering outside engineers and those who are practicing engineering at the time of the passing of the act, are similar to the requirements of the Joint Committee bill.

Colorado—Successful candidates receive certificates upon payment of a fee of $5. Those engaged in the practice of engineering at the time of the passage of the act are entitled to a license without examination upon payment of $15, provided that they have made such application within six months after the taking effect of the act.

Michigan—(1) For each initial certificate the fee is $10; for each subsequent annual renewal of certificate, issued by the board upon request of certified engineers, the fee is $5. Up to Oct. 15, 1919, the certificates are issued by the board upon a sworn statement of the applicant setting forth in full his training and experience and showing that he has been engaged as a principal in engineering for a period of not less than two years prior to Sept. 30, 1919. The board may permit engineers of other states and of foreign countries to engage as principals within the state when they present credentials showing that they have qualified for such work under appropriate laws of their own states or governments; (2) The other bill provides that in addition to the fee of $10 paid for certificate, a fee of $2 must be paid each year for the issuance of a renewal certificate. Any person engaged in the practice of engineering as a principal under the title of engineer before the passage of the act, having presented proof of competency and good character, may secure a certificate to use the title "registered engineer." Provision is made to permit architects and engineers of other states and foreign countries to practice architecture and engineering when they present credentials as in the case of bill (1).

Revocation and Reinstatement

6. Provisions for revocation and reinstatement are made as follows:

Joint Committee—Provides that the board may revoke a certificate of registration for fraud or deceit in practice or in the obtaining of the certificate or for the conviction of crime. Proceedings for revocation shall be begun by filing with the board written charges against the accused. These charges may be preferred by any person or corporation, or the board may on its own motion direct its secretary to prefer charges. The board shall designate not less than three of its members a committee to hear and determine said charges at a time and place to be fixed by the committee, and a copy of the charges shall be served upon the accused or his counsel at least 10 days before the date fixed. A two-thirds vote of all the members of the board shall be necessary for revocation. The board may reissue a certificate of registration to any person whose certificate has been revoked only after the expiration of one year from the date of the revocation, and for reasons which the board shall by a two-thirds vote of all its members determine to be satisfactory.

Wyoming—Licenses may be revoked if the character of the work or the moral fitness of the holder be judged as insufficient.

Louisiana—Licenses may be revoked upon conviction of immoral conduct before any competent court, and if the renewal license fee is not paid before Feb. 1 of each year.

Illinois—Any license may be revoked by a four-fifths vote of the State Board of Examiners for gross incompetency, or recklessness in the construction of buildings or other structures, or for fraudulently affixing seal to plans, drawings or specifications, or for any dishonest practice on the part of the holder, or for fraud in obtaining the license or practicing without payment of the annual license renewal fee. Provision is made for the holder to have at least 20 days' notice of the charge against him, of the time and place of the meeting of the board for the hearing and determining of such charge. The Circuit Court judges receive power to compel the attendance of witnesses upon the deliberations of the board. After one year, the board receives power to reinstate a petitioner according to its own rules and regulations, but it may require the petitioners to submit to an examination. A majority vote of the board is sufficient to reinstate.

Idaho—The State Engineer shall revoke surveyors' licenses upon the recommendation of a majority of the Board of Examiners for: (1) Failure to keep in force and effect the bond filed with the State Engineer; (2) gross incompetence, or fraudulent, dishonest, or unprofessional conduct on the part of the licensee in the conduct of his professional business.

Pennsylvania—Provides for revocation upon proof of fraud or deceit in obtaining registration, or in the practice of professional engineering; conviction of the crime of perjury, or larceny, or embezzlement or false pretense, or robbery, or burglary, or bribery, or corrupt solicitation, or forgery. It requires one month's written notice of the time and place of hearing, and the decision is not valid except by the vote of at least six members of the board. Reinstatement is allowed one year after revocation, provided six members of the board shall approve.

Indiana—Provides for revocation of license by a majority vote of the board, for incompetency or recklessness in the design of buildings or structures, or for dishonest practice or practices on the part of the holder. Twenty days' written notice is required. After the expiration of six months a person may have a new license issued to him, upon satisfactory evidence of proper reasons for such reinstatement and upon payment of $15. Dishonest practice is defined as follows: (1) To be guilty of fraud or misrepresentation in obtaining the license; (2) to conspire or attempt to conspire with any other person to violate the building or sanitary laws, and (3) to give or accept any valuable consideration as a bribe.

California—Exactly similar to the Joint Committee bill.

Colorado—The board shall receive power to inquire at any time into the identity of a person claiming to be a licensed engineer, and may revoke the license by a four-fifths vote in case the practitioner is guilty of any fraud or deceit in his practice, or is guilty of fraud or deceit by which he was granted a license, and if he is incompetent.

Michigan—(1) The board may revoke certificates for incompetence or dishonesty; (2) the other bill provides for revocation after 30 days' written notice and after a hearing, upon proof that the certificate was obtained by fraud or misrepresentation or that the holder has been guilty of malfeasance or gross incompetency in practice.

Penalties—Exemptions from Application

7. Penalties for violation, and exemption from the application of the laws are provided as follows:

Joint Committee—Violation by practicing without complying with requirements of the act is classed as a misdemeanor. The act, it is stated, shall not apply to any professional engineer working for the United States Government, nor employed as an assistant to a professional engineer registered under the act, nor to any engineer coming from without the state and employed therein until a sufficient time, prescribed by the rules of the board, shall have elapsed to permit registration—provided that before practicing within the state he shall have applied for the issuance to him of a certificate of registration and shall have paid the fee prescribed for admission to examination. The bill also suggests that a specified appropriation should be made for the use of the board for the payment of salaries and expenses under the act.

Louisiana—Violators of the act shall be fined not less than $25 nor more than $100, or they shall be imprisoned not less than 30 nor more than 90 days for each offense, by any court of competent jurisdiction. This does not apply to engineering departments of the United States, nor to civil engineers and surveyors of other states and territories when in actual consultation with registered civil engineers or surveyors of Louisiana, nor to any civil engineer or surveyor of the state actually practicing his profession before the passage of the act.

Illinois—Provides that any person guilty of the violation of its provisions shall be punished by fine of not less than $10 or more than $200 for each and every offense. It applies to structural engineers only.

Florida—Similar to the Joint Committee bill, and further provides that it shall not apply to any architect registered by Florida under the provisions of the act creating a State Board of Architecture.

The proposed bills contain the following penalties:

Pennsylvania—Any person shall be guilty of a misdemeanor who shall violate any provisions of the act, and upon conviction thereof he shall be sentenced to pay a fine not exceeding $1000 or undergo an imprisonment not exceeding one year, or both. The exemptions in application are prescribed as in the Joint Committee bill.

Indiana—Provides that after six months from the date when the law becomes effective it shall be a misdemeanor, punished by a fine of not less than $10 or more than $500 for each and every offense, for any person to practice architecture or structural engineering in Indiana without a license, or put out any sign, or card, or other device. The board shall cause the prosecution of all such persons violating the act.

California—Precisely similar to the Joint Committee bill.

Colorado—Violation is punished by a fine of $500 or by imprisonment of not more than six months, or both. It provides that nothing in the act shall be construed

to limit the rights, privileges and duties of architects licensed to practice under the architects' license law in Colorado.

Michigan—(1) Any person who fails to comply with the provisions of the act shall be ineligible for appointment or election to any state, county, township, city, village or other public office, where the duties involve one or more of the branches of engineering specified. Any person who engages in these branches of engineering except under a certificate shall be subject to a fine of $100 for the first offense, $500 or imprisonment for one year, or both, in the discretion of the court, for each and any subsequent offense. Plans, specifications, and estimates for all public work involving engineering must be prepared by certified engineers; (2) The other bill provides that any violation of its provisions shall be a misdemeanor, punishable for the first offense by a fine of not more than $100, and for subsequent offense by a fine of not more than $500, or imprisonment for not more than one year, or both. This act would repeal the act providing for the registration of architects, and all moneys remaining in the state treasury as a separate fund shall be transferred to a corresponding fund provided for by the new act.

Tests Show High Shears in Deep Reinforced-Concrete Beams

Preliminary Studies Made For Emergency Fleet Corporation's Concrete Ship Work Point to Desirable Higher Safe Units Than Those Now Permitted

By W. A. Slater

United States Bureau of Standards, on Duty With Emergency Fleet Corporation, Philadelphia, Penn.

PUBLISHED tests of reinforced-concrete beams have shown shearing strengths in the neighborhood of 100 to 150 lb. per square inch for beams with no web reinforcement, and seldom exceeding 300 lb. per square inch for beams with the most effective web reinforcement. Based on these tests, standards for design have been formulated and widely accepted which allow generally about 40 lb. per square inch working stress in shear for a beam with no web reinforcement, and a maximum of around 6% of the compressive strength of the concrete for beams having the most effective web reinforcement. Recent tests made for the Emergency Fleet Corporation in connection with the design of concrete ships indicate that for deep beams, at least, these values are much too small.

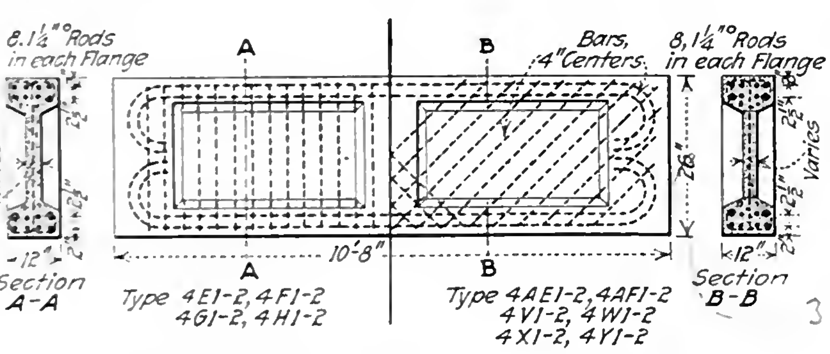


FIG. 1. TWO TYPES OF DEEP BEAM TESTED IN SHEAR
See table on p. 432 for further dimensions

For determining web reinforcement the following formulas have been almost universally adopted: $T = Vs/jd$ (for vertical stirrups); $T = \frac{2}{3} \times 0.7\ Vs/jd$. In which T = total load carried by one stirrup;

V = total shear on the section considered;

s = spacing of stirrups in the direction of the axis of the beam;

jd = moment arm of the resisting couple.

The maximum spacing of stirrups generally has been limited to values ranging from about $\frac{3}{4}\ jd$ to as much as jd.

The most obvious difficulty in designing a reinforced-concrete ship under existing standards was early found to be that of securing sufficient shearing strength without an undue weight of concrete in the shell. This led to the carrying out of a series of tests on beams designed to meet as far as practicable the conditions existing with a ship in service. The test beams were relatively deep compared to the span. The web thicknesses used (generally 3 or 4 in.) were such as seemed practicable for a ship. The heavy flanges used were necessary to enable sufficient longitudinal reinforcement to be used to carry the bending moment when a high shearing stress was present. At the same time, they may be considered to represent conditions which occur at the gunwale and at the bilge where there are large concentrations of reinforcement.

Heavy pilasters at the load-point and at the supports were necessary to prevent crushing of the web, due to the concentrated load at these points. From the phenomena of the tests it is apparent that an appreciable portion of the load was carried directly by the frame action of the heavy pilasters and flanges which were built monolithically with the beam. This portion of the load would not go to increasing the shearing stress in the web, and for an accurate measurement of the shear in the web it is necessary to make a correction for this load. However, the effect of the heavy frames in a ship will be somewhat analogous to that of the pilasters in the test beams. In structures other than ships (such as girders for railway or highway bridges), where high working stresses in shear would be advantageous, there usually will be present features which are analogous to the pilasters of the test beams.

The first series of tests for the Concrete Ship Section of the Emergency Fleet Corporation was carried out at the Pittsburgh laboratory of the Bureau of Standards. Thirteen beams 4 ft. 4 in. high and 18 ft. 6 in. long, and one beam 10 ft. high and 22 ft. long were tested in this series. These tests afforded a basis for concluding that the high working shearing stresses used in the design of the first Government concrete ship were safe. Also, as a result of these tests, tentative standards for shear design for concrete ships were drawn up. However, certain features needed more thor-

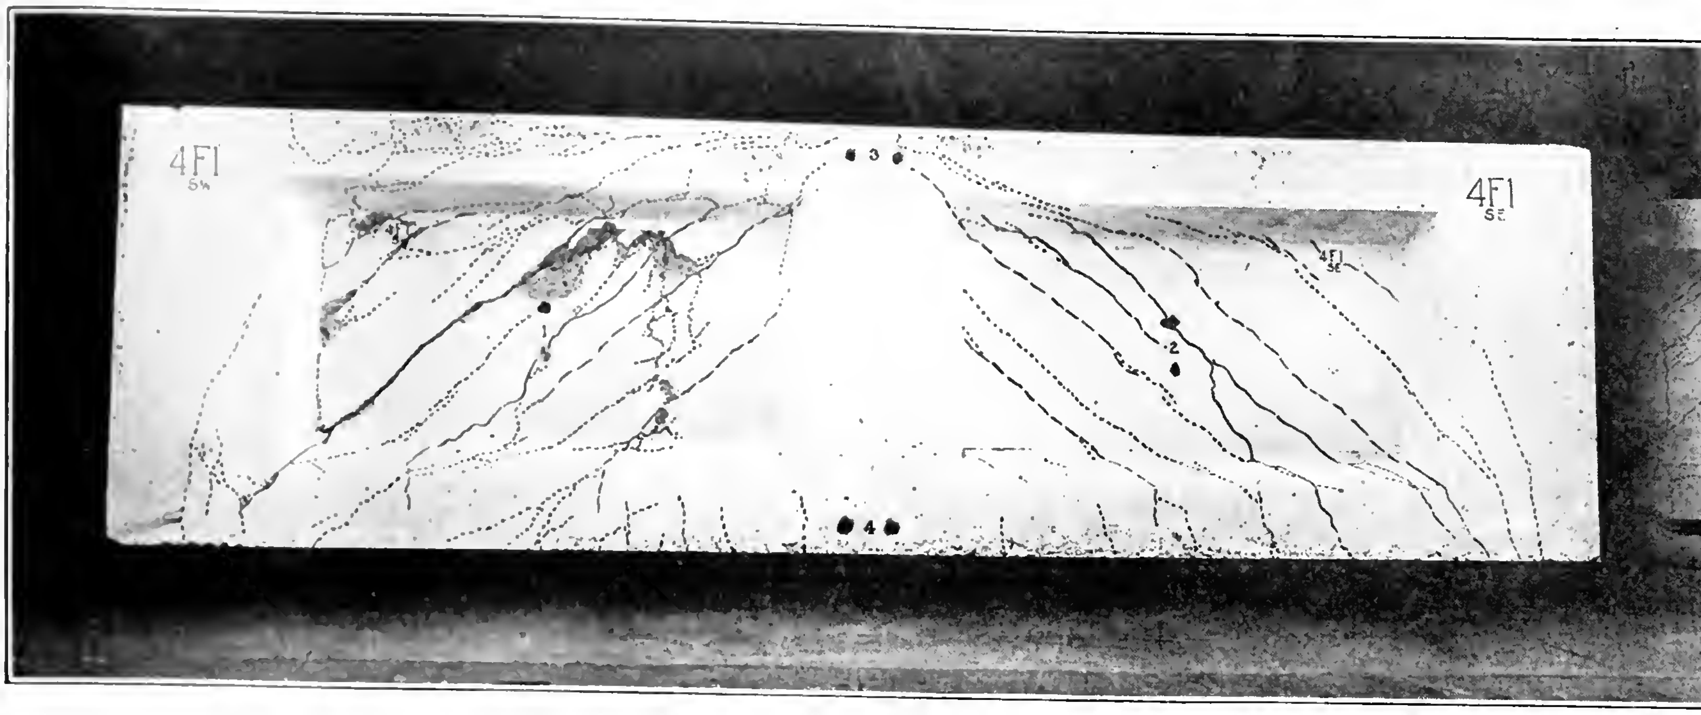

FIG. 2. SHEAR CRACKS IN DEEP CONCRETE BEAM TESTED FOR CONCRETE SHIP WORK
Solid lines cracks under 400 lb. per square inch shear. Dashed lines cracks under 800 lb. per square inch shear. Dotted lines cracks under maximum load

ough examination, and a second series of tests was laid out which covered a much wider range of conditions than those involved in the Pittsburgh specimens.

This second series of tests was carried out in the Fritz Engineering Laboratory at Lehigh University, Bethlehem, Penn. The full use of this laboratory, without charge, has been given to the Emergency Fleet Corporation for this work, and the university officials have coöperated freely in making the work successful.

These beams were 10 ft. 8 in. long and 36 in. deep, 12 in. wide at flanges and of varying web thickness. All the beams were of I-shaped cross-section, with eight 1¼-in. round bars for longitudinal reinforcement in the top and in the bottom. The form of the beams and the manner of reinforcement are shown in Fig. 1. The reinforcing bars were of steel rejected from shrapnel manufacture, and had a yield-point stress of approximately 60,000 lb. per square inch. All the web reinforcement was of round bars of the sizes given in the accompanying table. They were spaced at distances of 4 in. in a direction normal to the axis of the bar in all cases. They were hooked over the longitudinal reinforcing bars at the top and at the bottom of the beam, but were not welded in any instances. The beams were tested at an age of about 60 days, and 8 x 16-in. control cylinders made with the beams were tested at the same time. The strengths of the control cylinders are shown in the table.

Fig. 2 is a view showing the appearance of a typical beam after failure. The cracks in the beam were painted to make them visible in the photograph and to distinguish these occurring at different loads. The cracks shown as solid lines were present when the shearing stress was 400 lb. per square inch. The dashed lines represent cracks at 800 lb. per square inch shear, and dotted lines those at the maximum load carried by the beam. The holes in the concrete were made to expose the steel for purposes of strain-gage readings. Due to the painting of the cracks in Fig. 2, their prominence is exaggerated; that this is so is indicated in Fig. 3, a view of beam 4F2. This beam is a companion specimen of 4F1, shown in Fig. 2. The photograph was taken at the end where failure occurred and without first having the cracks painted.

Fig. 4 shows the observed stresses, center deflection and average widths of the largest cracks for a typical beam. In this diagram tension stresses were plotted upward and compression stresses downward. The numbers on the curves refer to gage lines shown in Fig. 2. Gage lines 5 and 6 were in positions corresponding to the positions of gage lines 3 and 4, respectively, but were on the opposite side of the beam.

Fig. 4 gives an idea of the behavior of a typical beam during the test. Attention is called to the regularity of the curve showing maximum crack widths. The first point on this curve indicates the first measurement of crack width. The dotted line indicates the origin for this curve and does not indicate the crack width for loads below the first point.

The deflection shown is larger than is accounted for by flexure alone. This will be seen if the stresses for gage lines 3 and 5, and 4 and 6, all of which were on reinforcing bars, be reduced to unit deformations and applied in the deflection formula:

$$D = 0.833 \frac{l^2}{d} (e_c + e_s)$$

in which D = deflection
l = span
d = vertical distance between measurements
e_c = unit deformation in upper bars
e_s = unit deformation in lower bars

An examination of G. A. Maney's article in the "Proceedings" of the American Society for Testing Materials, 1914, p. 311, shows the substantial correctness of this formula for beams in which the shearing deflection is negligible. The indication is that the high shearing stress developed and the opening of diagonal cracks had an important effect on the deflection.

Test results for a few of the beams of this series are given in the table. The shearing stresses given in the table are based on the assumption that all the load was carried by flexure of the beam as a whole, and, consequently, that all the shear passed through the web of the beam. This must be somewhat in error, because with

For cases in which the stress in the stirrups had passed the yield-point it is so indicated in the table by the initials Y.P.

the monolithic construction of the beam the flanges and pilasters would act as a frame to some extent independently of the beam structure, and would carry loads which did not have to pass through the web in shear. The amount of this error is not known, but it seems that it cannot be more than the total load carried by a beam like 4AG1 and 4AG2, and it probably is somewhat less. In these beams the web was entirely absent and the loads were carried by frame action alone. To carry load by the frame action of the flanges and end pilasters relatively large deflection is necessary. This is indicated by the large amount of deflection at maximum load given in the table for beams 4AG1 and 4AG2. When the web is present, deflection is prevented to a certain extent by the shearing stresses set up in the web, and the load carried by frame action must be correspondingly less. In later tests, measurements will be made in an effort to determine how much of the shear passes through the web.

The observed stresses in the reinforcement at maximum load, as given in the table, are in most cases greater than were indicated by the strain-gage readings. Usually, after the maximum load was reached the yielding of the beam was so rapid that the load fell off and the stresses were relieved. This is illustrated in Fig. 4, which indicates that the stress in the longitudinal reinforcement increased progressively up to the load just before the maximum but that it had decreased at the maximum load. For such cases the load-stress curves were produced to obtain the most probable stress value for the maximum load.

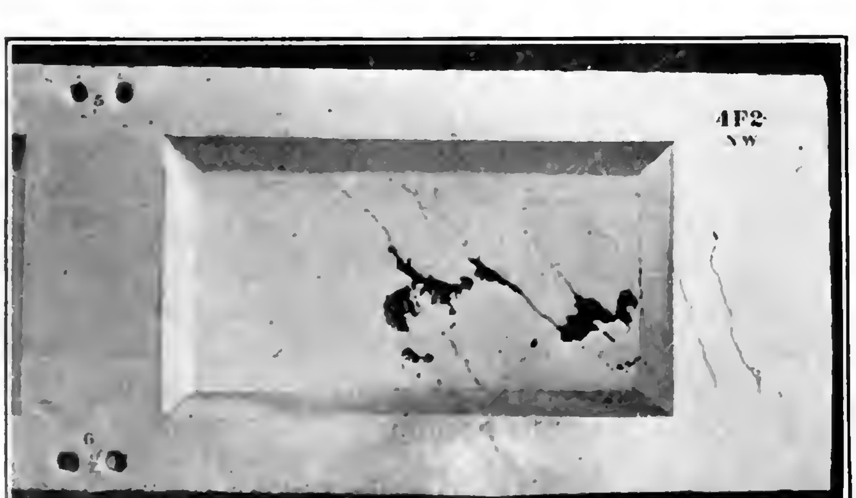

FIG. 3. SHEAR CRACKS IN BEAM UNDER MAXIMUM LOAD

Up to the time of this report, about 85 beams in all had been tested. This investigation was designed to cover the conditions met in ship practice, and, besides

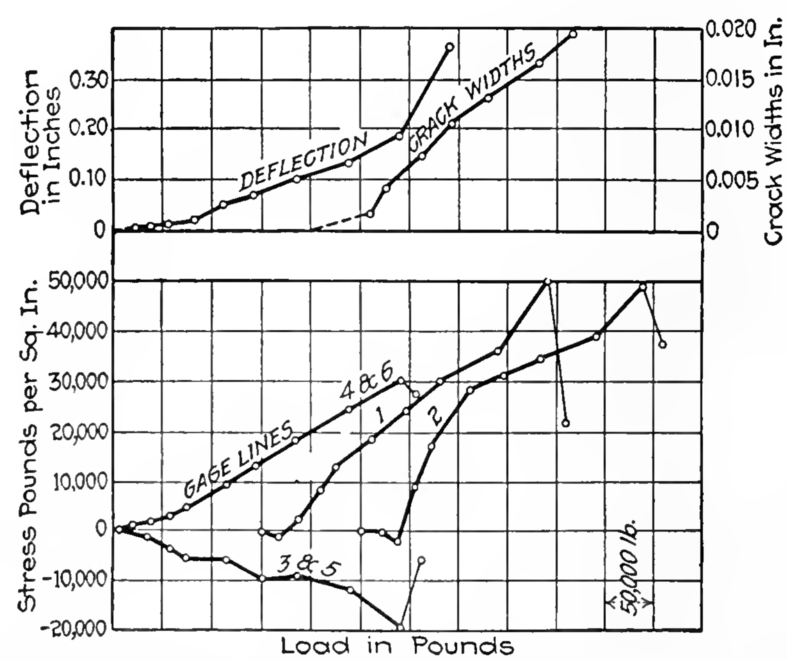

FIG. 4. VARIATION IN DEFLECTION AND CRACK WIDTHS WITH LOAD AND STRESS

the results given in this article, involves beams with longitudinal reinforcement in the web and beams with diagonal compression reinforcement. Expanded metal also was used as web reinforcement in certain of the test beams. Although certain important conclusions are suggested by the test results already obtained it is not the purpose of this article to discuss generally the significance of the results. The investigation is incomplete, and later results may cause important modifications of present indications. One fact which stands out, however, is that with beams of this type larger shearing stresses could be used safely than those which are recognized in standard building regulations. In order to establish the safety of increasing the allowable shearing stresses in general practice, the investigation needs to be extended along lines which in this series of tests have scarcely been touched. This extension should

determine the effect of (a) variation in spacing of stirrups; (b) variation in ratio of depth to span of beam; (c) variation in strength of concrete used; (d) variation in depth of embedment of stirrups for anchorage; (e) variation in amount of longitudinal reinforcement.

Considering these results in relation to general practice in reinforced concrete, it does not seem unreasonable to expect that the establishment of shearing strengths of reinforced-concrete beams for the variety of conditions enumerated will mark a distinct step in advance in the application of concrete to buildings and bridges where now the limitations in shearing strength either prevent its use entirely or seriously handicap economical design.

A continuation of these investigations by the Emergency Fleet Corporation cannot be made, but plans are under way for a larger investigation by the Bureau of Standards, to give information on the subjects enumerated in the preceding paragraph. Such an investigation adequately conducted will be expensive. While funds are not now in sight for the carrying out of the entire program, efforts are being made to secure the financial support that is necessary to do justice to this important subject.

The Angle as a Beam

Section Moduli for Angles of Various Sizes in Various Positions Tabulated for Comparison

By R. Fleming
American Bridge Company, New York City

VALUES for the section modulus of various angles in the positions shown by Figs. 1, 2, 3 and 4 are shown in the accompanying Table I.

The common method of calculating the strength of an angle beam with load normal to one of the legs is by substituting the values of I and c, taken from the manufacturers' handbooks, in the flexure formula, $M = fs = f(I/c)$ and solving for f. This, however, assumes that the neutral axis is parallel to one of the legs and that the angle can deflect only in a vertical direction. The Carnegie "Pocket Companion" and other handbooks give tables of allowable uniform load on angles as beams. In all cases it is stated that the tables are based on the neutral axis parallel to one of the legs. From the columns headed Fig. 1 and Fig. 2 in Table I it will be noted that the section moduli and therefore the allowable normal loads for angles used as beams free to bend in any direction are about 75% of those for angles stayed against lateral movement.

TABLE I. VALUES OF SECTION MODULUS FOR POSITIONS OF ANGLE SHOWN IN FIGS. 1-4

Angle, Inches	Fig. 1	Fig. 2	Fig. 3	Fig. 4
2 x2 x$\frac{1}{4}$	0.25	0.18	0.26	0.17

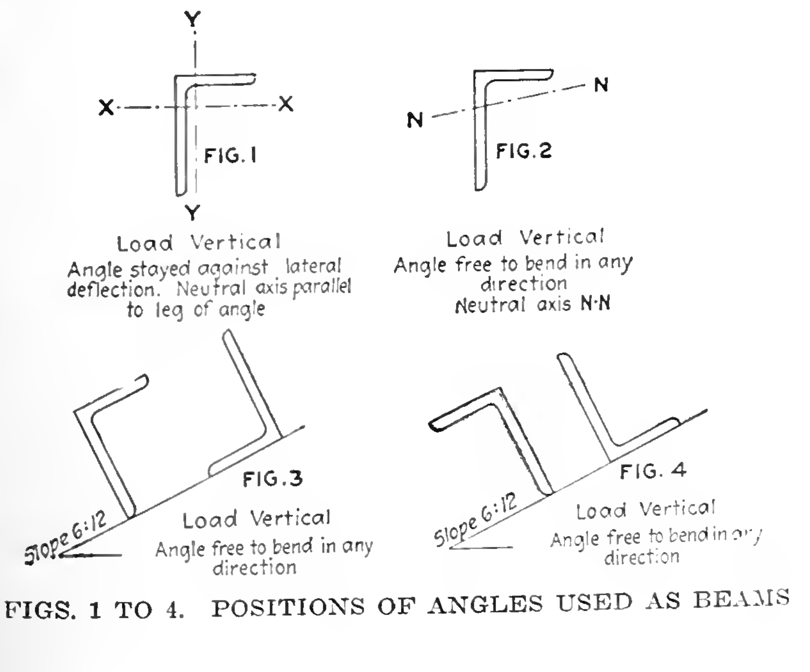

FIGS. 1 TO 4. POSITIONS OF ANGLES USED AS BEAMS

The most frequent use of angles as beams is for purlins on sloping roofs. Textbooks do not mention that purlins set as shown in Fig. 3 are stronger than when set as in Fig. 4. It is evidently taken for granted that a designer should know this without being specifically told by a textbook. Yet, either through ignorance or to suit local conditions, purlins are sometimes set as shown in Fig. 4. They are so shown in a number of handbooks. By consulting Table I it may be seen that the purlins of Fig. 4 have but 51% to 67% of the strength of the purlins of Fig. 3. Table II is given for reference. The

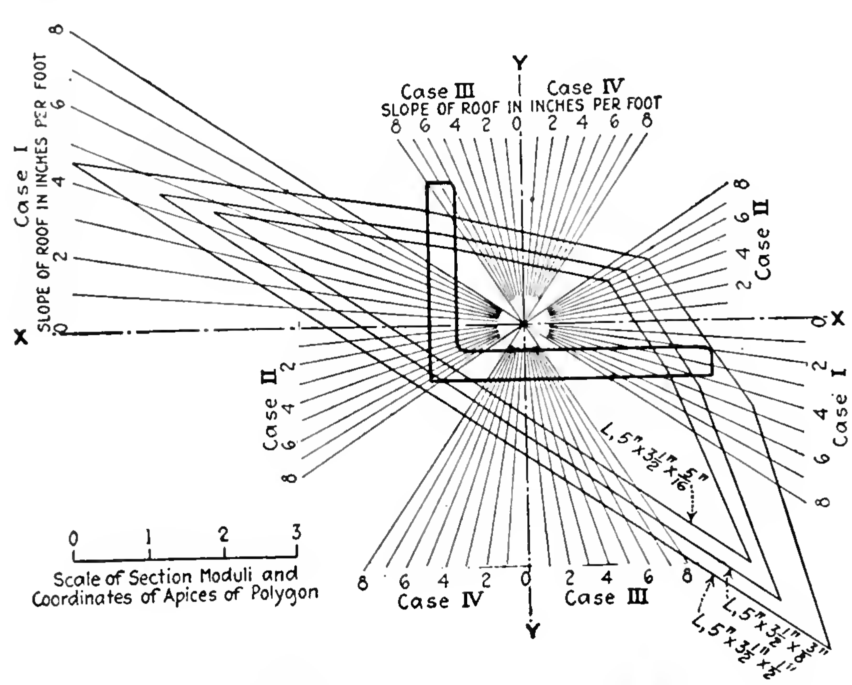

FIG. 5. DETERMINATION OF SECTION MODULI FOR THREE ANGLES BY S-POLYGONS

angles are assumed to be set as in Fig. 3. It may be mentioned that the section moduli in both tables, except those for Fig. 1, have been scaled from carefully drawn "S-polygons." Three of these polygons are shown in Fig. 5. The coördinates of the apices are taken from the late Professor Waterbury's "Stresses in Structural Steel Angles." Case I is for the angle turned as in Fig. 3, Case II as in Fig. 4, and Cases III and IV as in Figs. 3 and 4, with the short leg at right angles to the rafter. The *shorter* distance from the origin of coördinates to the perimeter of the polygon should be used as the section modulus for each slope.

Shipyard on New Orleans Canal For Building "Unsinkables"

Range of Mississippi River Stage Determined Location—Work Started When Navigable Water Was Five Miles Away—Fabricating Shop a Group of 35-Foot Working Bays—Tractors Haul Material to Berths

WHEN the Foundation Co. drove the first piles for its New Orleans shipyard in the spring of 1917 the nearest navigable water was five miles away. Since then, dredges working on the new industrial canal for the City of New Orleans have cut a channel to the shipyard site, and before the first vessel is ready to start on her trial trip the canal will be open to deep water.

The location of a yard at New Orleans involved conditions differing widely from those in other parts of the country. The Mississippi River has a range of over 20 ft. in elevation making it unsafe to cut through the levee for launching ways. Lake Pontchartrain, on the other hand, has a depth of only 9 ft., which is, of course, insufficient for large-sized vessels. Advantage was therefore taken of the ship canal, from the river to the lake, which the city is now building for industrial development. A lock near the river bank will maintain the canal at the level of Lake Pontchartrain. The ordinary variation in the lake is only 2 or 3 ft., due to the small tide in the Gulf of Mexico, though after exceptionally heavy storms there may be a variation of as much as 8 ft. An excellent shipyard site is also provided beside the wide turning basin at about mid-length of the canal.

The property developed by the Foundation Co. is on the west bank of the basin, adjoining a built-up section of New Orleans. As electric cars provide quick access to the center of the city, no housing problem for labor is involved. The yard is served by the Public Belt R.R. and is supplied with water and electricity from the city systems.

The size of the turning basin will permit end launching of the hulls, which has advantages over side launch-

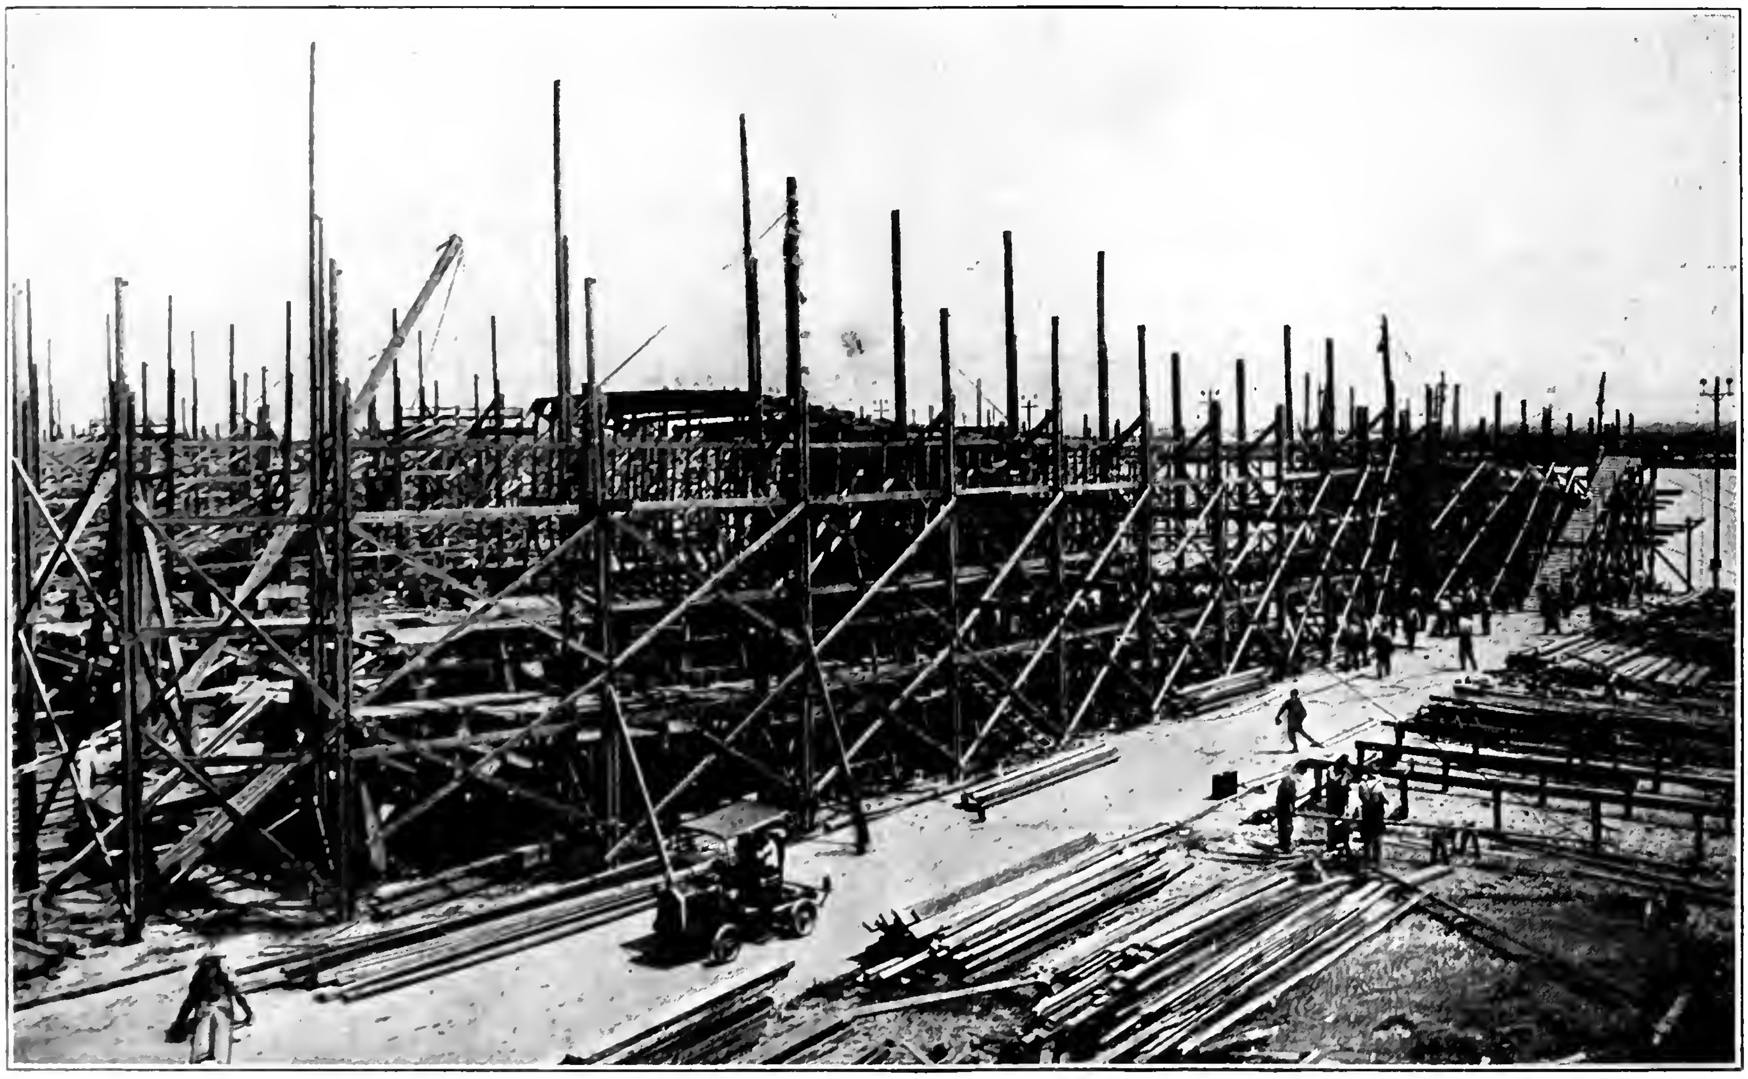

FIG. 1. SHIPYARD BEFORE COMPLETION OF DERRICK TOWERS; A FLEET OF TRACTORS LIKE THAT IN FOREGROUND DOES MOST OF YARD HAULAGE

ing in economy of water front and ease in handling material. There is ample space also, for laying up vessels to be fitted out.

Plate Yard Served by Locomotive Cranes.—Raw steel is brought into the yard (see the plan, Fig. 2) on a standard-gage railroad track, and is distributed in the storage yard so that plates are near one end of the plate-and-angle shop, and angles and shapes near the opposite end. Steel is unloaded from the cars and stored by locomotive cranes. These cranes also load the material on small cars and push them into the ends of the plate-and-angle shop, where the material is handled by an overhead traveling crane.

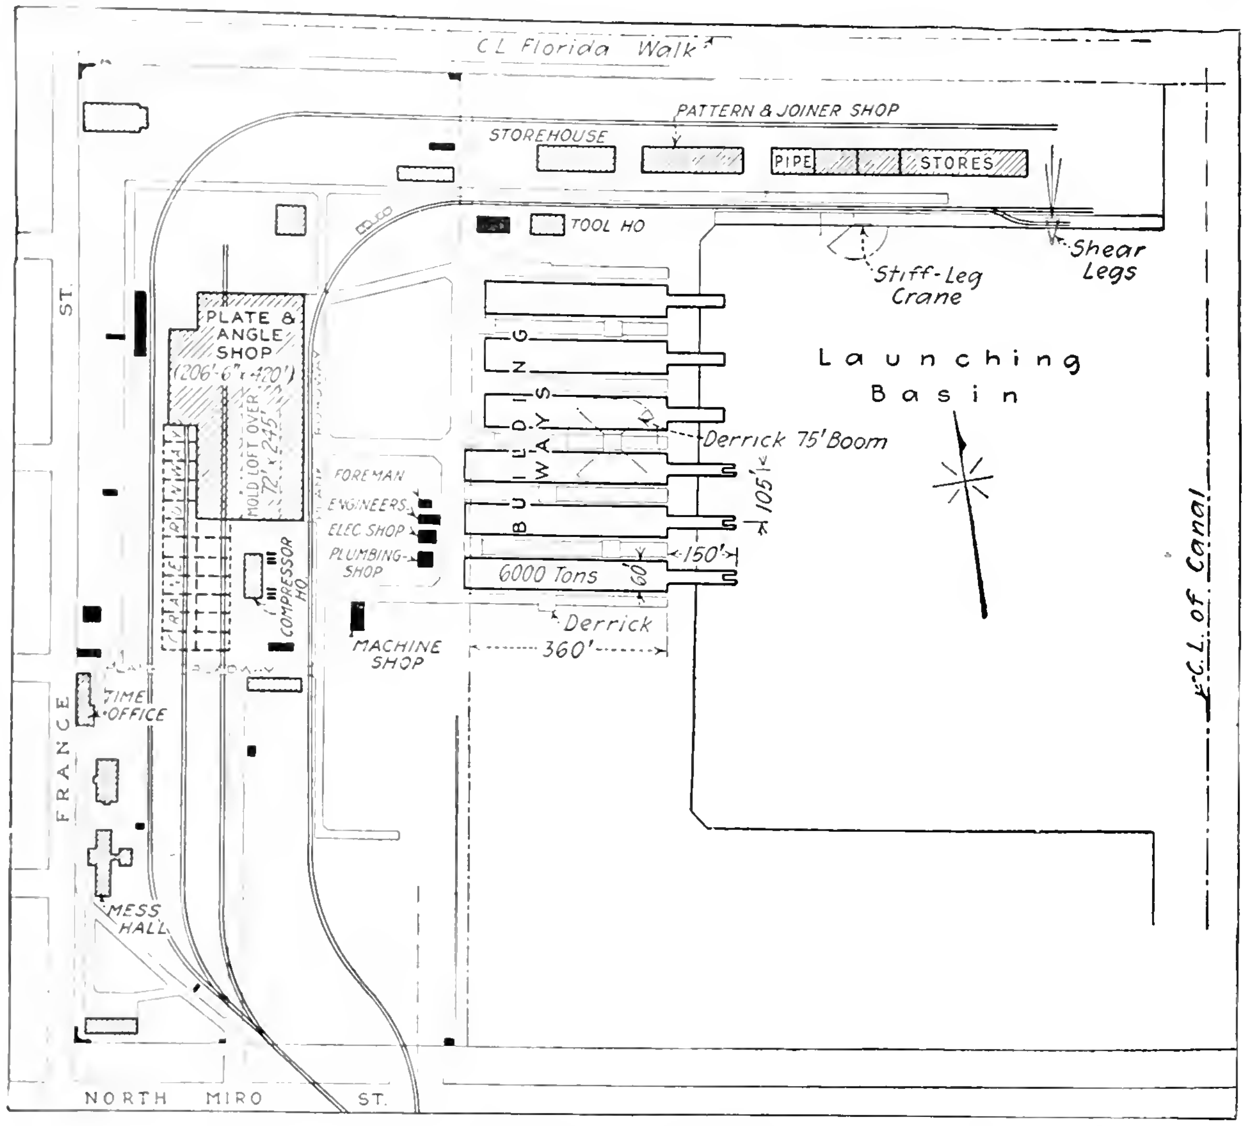

FIG. 2. PLAN OF YARD—FIVE END-LAUNCHING WAYS; LARGE STORAGE SPACE BETWEEN SHOP AND WAYS

The plate-and-angle shop is located just far enough back of the building ways to leave ample space for the storage of fabricated material before erection in the hulls. It is a timber-frame building (Fig. 4) 206 x 350 ft., with post spacing 24 ft. by 35 ft. The roof is of sawtooth construction, with provision for ample lighting of the interior. The sides are not covered below the bottom chords of the trusses, except around the north end, where the machine-shop equipment is located.

Fabricating-Shop Layout—A craneway runs along the entire length of the west side of the shop and extends beyond it 315 ft. over the steel-storage yard. It carries a five-ton electric traveling crane of 60-ft. span. The crane handles raw stock coming into the building from either end, loads material on working skids from cars, or places it so that it can be picked up by one of the two-ton hand cranes which extend along the nine small transverse bays along the east side of the shop.

In the 60-ft. bay of the shop, where raw steel is received, are the layout skids for plates, angles and shapes. The furnaces are in a leanto at one side. Each cross-bay, Fig. 3, is laid out to handle a separate class of work, and contains the tools necessary for the operations to be performed.

The northerly bay, between columns 1 and 2, is inclosed, and forms the machine shop. South of it, the bay between columns 2 and 3 is devoted to forging; it contains the hand forges, a small annealing furnace, and hammers. The next three bays, between columns 3 and 6, are for working angles and frame stock, and contain the angle and beam shears, punches and benders. The remaining five bays contain the plate shop equipment. Its principal punching units are five 30-ft. Lysholm plate tables, operated in conjunction with 36-in. and 60-in. vertical punches. From these punch tables, plates are worked ahead to the radial countersinking and drilling machines and to the 30-ft. plate bending rolls at the east side of the building, between columns 6 and 7.

Tractor Haulage System—The yard was originally laid out with railroad tracks running to the shipways. Locomotive cranes were to be provided, so that cars could be unloaded either at the storage piles or at the ways. This method was abandoned later, however, and a tractor system substituted.

Five small gasoline tractors, manufactured by the S. K. Prescott Co., Seattle, Wash., provide the motive power. These tractors, one of which can be seen in the view, Fig. 1, are equipped with a 22-hp. four-cylinder Ford motor; they weigh 2800 lb., and can travel from three to 20 miles an hour. A number of four-wheeled trailers are also provided.

A system of plank roadways is built through the plate-and-angle shop and around the yard, so that tractors and trailers can carry materials to any point where they are needed. Light pieces are loaded and unloaded by hand; heavy pieces are loaded at the shop by the two-ton overhead cranes, and are unloaded at the storage piles by small stiffleg derricks conveniently located. When fabricated work is taken directly to the ways, the trailers are unloaded by the tower derricks.

Tower Derricks—Material is handled at the building slips by tower derricks. These consist of timber towers 32 ft. square, ranging from 35 to 48 ft. high, the 48-ft. towers being near the head of the ways. The yard plan, Fig. 2, indicates their position with respect to the

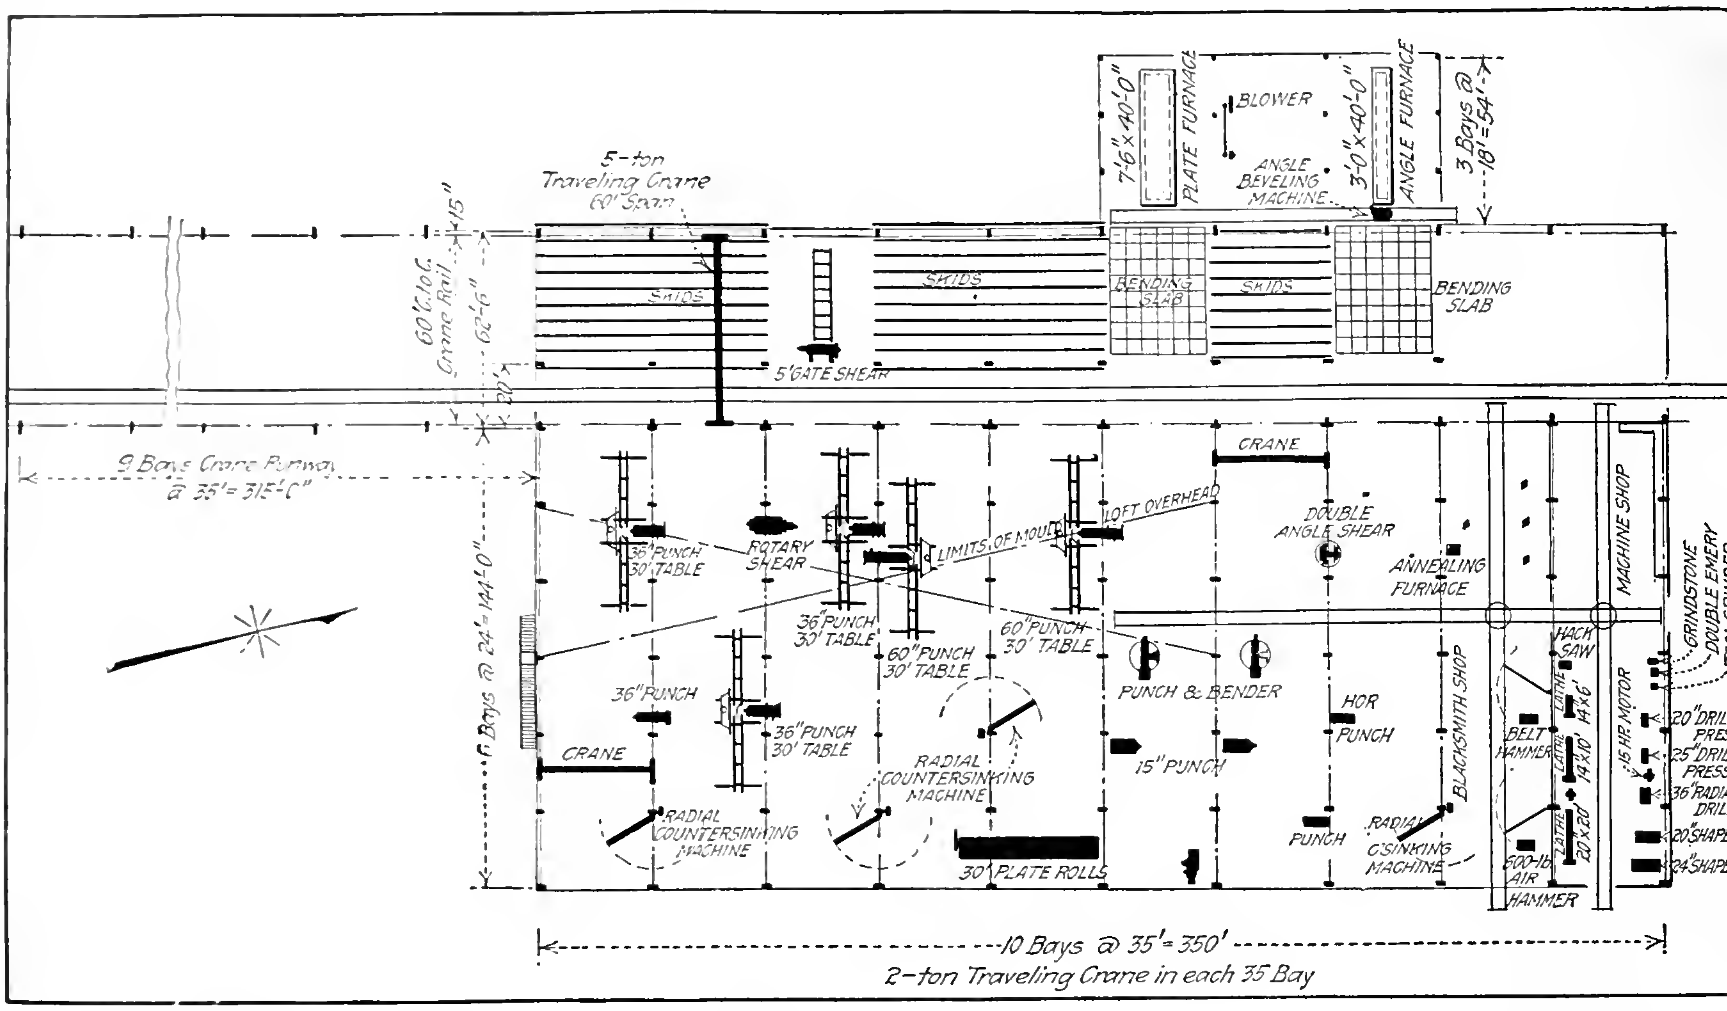

FIG. 3. MATERIAL ENTERS WIDE LAYOUT BAY OF SHOP AND MOVES THENCE CROSSWISE ALONG ANY OF NINE FABRICATING AISLES

slips. Each tower carries a Terry standard steel derrick with 75-ft. boom, having a capacity of five tons at 75 ft. or 15 tons at 45 ft. The derrick is not fixed on the tower, but is set on a turntable. This device allows the mast to be swung to four different positions, so that the derrick can cover an area nearly 100 ft. in radius, and yet has the advantages of the speed and lightness of a shorter boom.

Wharves along the side of the launching basin serve in fitting out the hulls. A 10-ton derrick is set up on one of these wharves, and a 65-ton shear leg on the other wharf. The buildings used in fitting out the vessels, such as the joiner shop, the sheet-metal shop, the electrical shop, the pipe shop, and the storehouse for fittings, are all located conveniently to the wharves. Standard-gage railroad tracks and planked roadways for motor trucks are provided for the delivery of materials. From these shops, fabricated materials will be delivered to the wharves by motor tractors.

Timber Shear-Leg Derrick—The shears have a lifting capacity of 65 tons, sufficient to permit handling a Scotch boiler of the size to be used in these vessels, from the flat-car to the hull. A canvass of the derrick manufacturers developed the fact that none of them had standard designs for such a derrick; in fact, the few derricks of this type built have been largely designed and assembled by the owners. The engineers of the Foundation Co. therefore designed their own shears. Economy and ease of obtaining parts in the open market received first consideration.

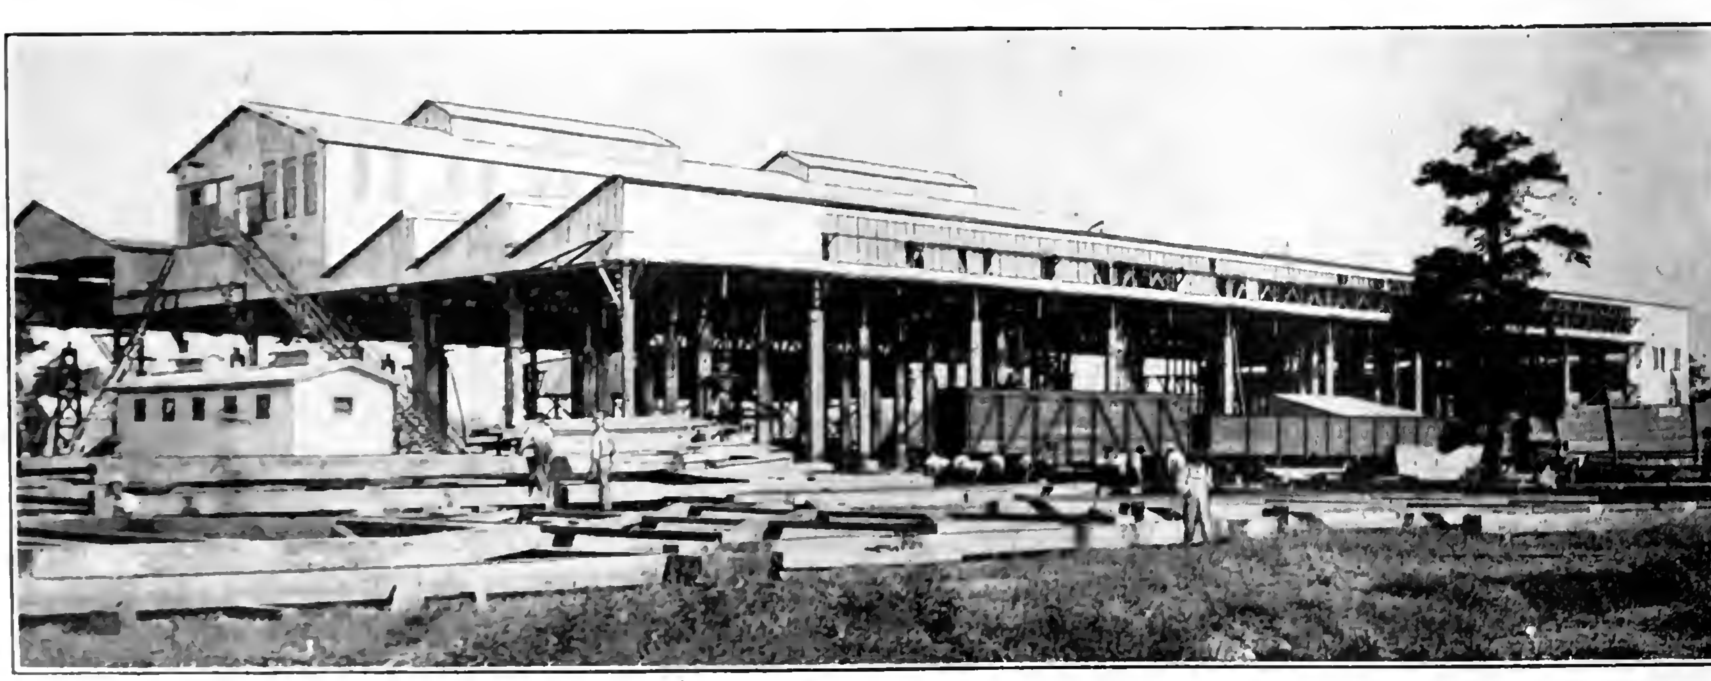

FIG. 4. TIMBER-FRAME FABRICATING SHOP WITH OPEN SIDES

The machine comprises a vertical A-frame or mast 99 ft. high, and a tilting A-frame or boom 99 ft. long, each leg of which was built of four pieces of 12 x 12-in. long-leaf yellow pine, bolted together and spliced with steel plates, as shown in Fig. 5. Instead of having the usual backstay of timber or steel, the mast is guyed fore and aft by means of 1¼-in. plow-steel cable, the forward guys being attached to the wharf construction at the water's edge, while the back guys are carried 100 ft. to the rear of the mast and anchored to concrete blocks built on pile foundations.

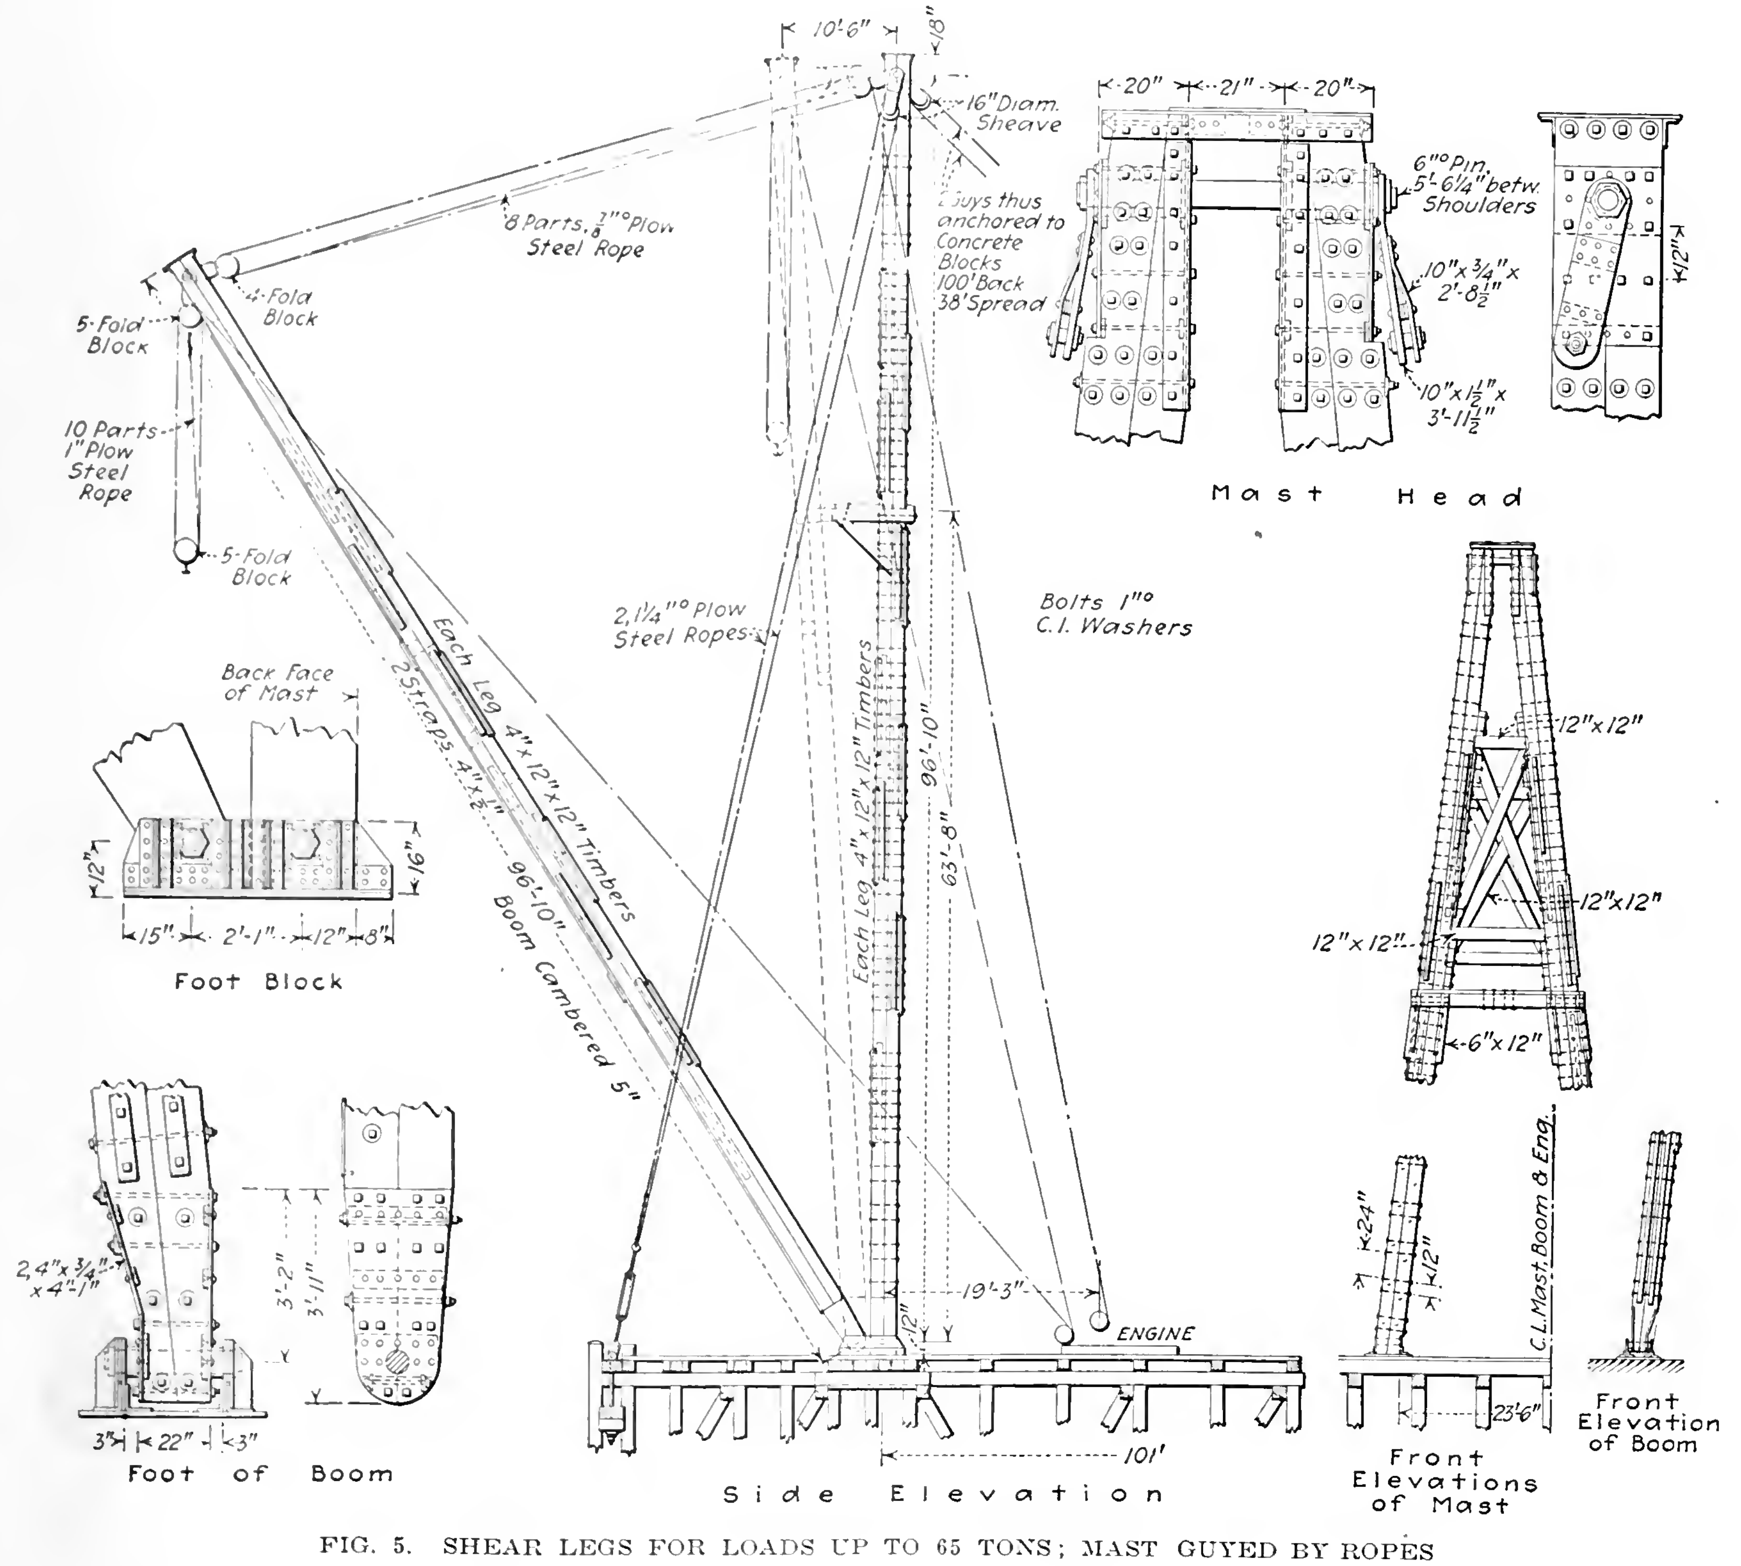

FIG. 5. SHEAR LEGS FOR LOADS UP TO 65 TONS; MAST GUYED BY ROPES

The mast and boom heads and foot blocks were built of standard structural shapes. The whole framed structure was so designed that the rough timber and structural steel could be delivered to the shipyard, and be fabricated and erected; the exception to this being the pins through the mast and boom heads and foot blocks, which were purchased already fabricated. All blocks, shackles, cables and cable fittings were stock material purchased in the open market. The hoisting engine is a double-drum electrically driven machine having the capacity to hoist 14,000 lb. 100 ft. per minute.

Motor-generator sets to furnish current for crane and derrick service are located in the compressor house, situated near one end of the plate-and-angle shop, whence it can furnish air to shop and ways with minimum length of distributing lines. Motor-driven air compressors of 4500 cu.ft. per minute capacity are installed in the compressor house.

At present there are three building ways, but space has been left and the whole layout arranged so that five additional ways can be installed. There is also room for the construction of a complete repair yard with drydock facilities.

The Foundation Co. is building at this yard for the French Government five 4250-ton dead-weight capacity steel cargo steamers of the "Le Parmentier" "unsinkable" type.

Unlike previous designs, which involve modifications of a standard cargo steamer, the "Le Parmentier" design makes a radical departure from usual forms of ship construction, as will be noted in the sketch, Fig. 6. In external appearance the vessel resembles whaleback steamers, but its cross-section is in the form of two circles side

by side, connected above and below by curved segments.

The hull consists of two parallel cylinders 20 ft. in diameter, arranged horizontally side by side and connected by transverse water-tight bottom and deck. The cylindrical form not only gives maximum strength, but also provides double inner longitudinal walls to localize flooding of the hull if the outer skin is ruptured. The

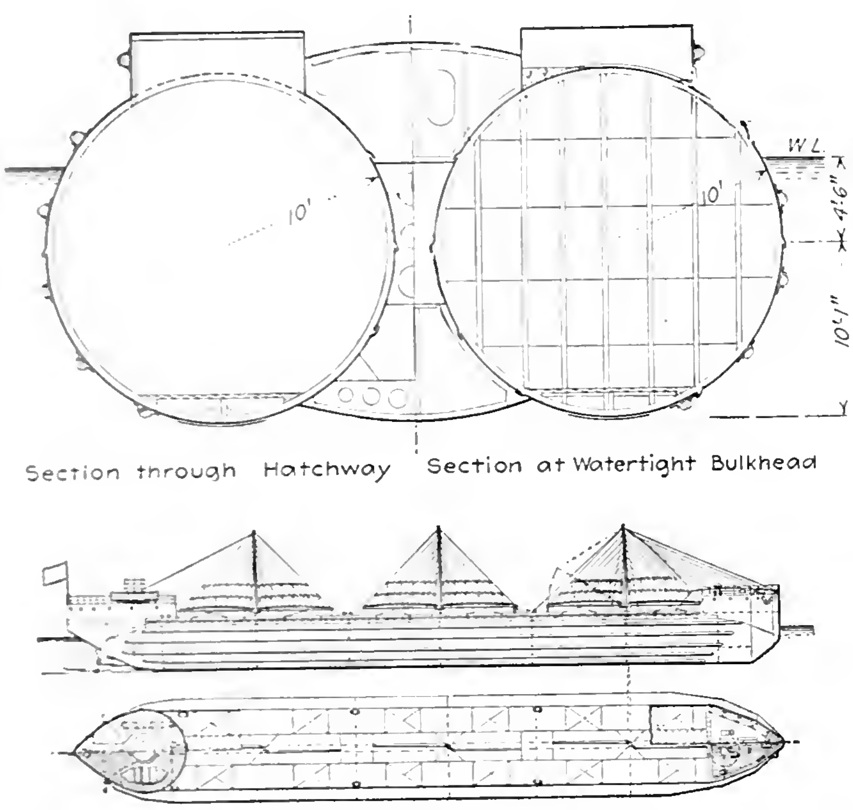

FIG. 6. FRENCH "UNSINKABLE" SHIP, "LE PARMENTIER" TYPE BUILDING AT NEW ORLEANS

entire hull is stiffened and receives further protection from flooding by seven transverse water-tight bulkheads, which divide the hull into 24 separate compartments.

The steamers now under construction are 328 ft. 4 in. long over all; 46 ft. 5 in. in beam, and 16 ft. 1½ in. in maximum draft. The propelling machinery will consist of twin triple-expansion 700 hp. engines, designed to give the vessel a speed of approximately eight knots, loaded. Steam will be supplied by Scotch boilers fired with oil fuel.

As one complete power plant is installed in each half of the hull, the vessel can be brought into port even though one side has been completely flooded.

According to the present schedule, the first hull will be launched soon, and will be completely equipped ready for service in the latter part of the summer.

The New Orleans yard is the largest of the three steel shipbuilding plants controlled by the Foundation Co.; the other two being at Savannah, Ga., and Port Huron, Mich.

The Foundation Co.'s experience in shipbuilding began in July, 1917, when it laid the keel of a 3500-ton Ferris-type ship for the Emergency Fleet Corporation. Since then it has completed 40 wooden auxiliary schooners and 15 cargo-steamer hulls, with a total deadweight capacity of 169,000 tons—a greater production than is credited to any other wooden shipbuilding organization in the country.

Franklin Remington is president and John W. Doty is vice-president of the company. Construction is under the supervision of C. A. D. Bayley and Bayly Hipkins, vice-presidents in charge of shipbuilding on the Atlantic and Pacific Coasts, respectively. H. J. Deutschbein is general manager and Cox & Stevens are the consulting naval architects of the company.

Motor Truck Costs Much Higher Than Generally Assumed

Data Collected by Motor Truck Association Show High Average Operation Expense — New Cost System To Be Recommended

OPERATION cost for motor trucks was the subject discussed at a recent informal meeting of the Motor Truck Association of America, the purpose being to start investigation and determine a proper cost-accounting system. It was asserted that many published costs are much too low and work injury to contractors and haulage companies basing charges upon them, and putting the stigma of overcharge upon those who place their charges high enough to meet actual conditions. As a basis for the investigation, the cost for a five-ton gasoline truck shown in detail in Table I was submitted by one of the largest operators of trucks in the East.

TABLE I. COST PER DAY OPERATED FOR FIVE-TON GASOLINE UNIT BASED ON 50 MILES PER DAY PER TRUCK AND 300 DAYS PER YEAR

	Amount	Totals
Direct Charges		
Driver	$5.00	......
Tires, based on present cost of tires (guaranteed basis)	3.00	......
Oil, grease, kerosene, graphite, etc.	.50	......
Gasoline, 3½ miles to gallon = 14 gallons @ 25c. per gallon (average)	3.50	$12.00
Indirect and Overhead Charges		
Depreciation, 20% on $6,000 investment	4.00	
Interest, 6% on $6,000 investment	1.20	
Insurance, averaged at $450 per year	1.50	
Garage, rental, upkeep, etc., $300 per year per car	1.00	
Maintenance, minor repairs, supplies, tire chains, tools, lamps, springs, spark plugs, equipment, etc. (estimated)	1.00	
Overhaul, complete, pro-rated, $600 yearly	2.00	
License fee	.20	
Body upkeep, repairs and painting	.30	11.20
Supervision, based on 10% of above costs		2.32
Lost time—time lost in repairs, no work, weather, or other causes 20% of total less gas, tires and oil, etc., $7		3.70
Total cost per day operated		$29.22

with the suggestion that it be sent out to all truck operators, requesting them to criticise it and submit their own costs for the information of the association.

The table is based upon actual experience; it is assumed that the truck makes 50 miles per day and works 300 days per year. The direct charges are accumulating only while the truck is under operation, while the indirect are those which are accumulating whether the truck runs or not. Supervision includes all office expenses, stationery, printing, advertising, office help, telephone charges, outside men, etc. The cost of mechanical garage equipment, power, spare parts, etc., with interest on the same, and depreciation, is included in the amount charged to maintenance and overhaul.

Average operating conditions as to load were used in compiling this table. Up to the present time these have equaled a full load one way or, for a 50-mile day, transportation of 125 ton-miles at about 24c. per ton-mile. The costs are actual, no profit being included to cover risks, etc.

Table II gives the costs as sent in by six trucking

companies in answer to the inquiry. The averages shown in the last two columns include the figures in Table I.

In considering the returns, it will be noted that many of the differences are in such elusive items as overhead, supervision, and lost time. The averages in the last two columns were obtained by adding the amounts together and dividing by the number of reports on that item. The average total cost per day, while somewhat less than the suggestion sent out, in the main agrees very well. In sending out the suggestion, it was not thought that there would be agreement within several dollars, but it was believed that a much higher cost would be shown than is generally supposed.

TABLE II. ANSWERS RECEIVED ON THE INQUIRY SENT OUT, USING THE SAME ITEMS AND BASIS FOR FIGURES

	A	B	C	D	E	F	Average	
	Amt.	Amt.	Amt.	Amt.	Amt.	Amt.	Amt.	Total
Direct Charges								
Driver	$5 00	$5 20	$5 00	$5 00	$5 17	$5.50	$5 13	
Tires	3 00	3 75	2 00	2.00	2 00	3 00	2 68	
Oil, etc	30	.	.30	50	25	25	.35	
Gasolene	3 00	4 00	3 50	4 65	2 08	3 75	3.50	
								$11.66
Indirect Charges								
Depreciation	$3 50	$4 19	$3 60	$3 40	$3 67	$4 00	$3 77	
Interest on Investment	1 20	1 26	1.08	1 22	1 10	1 00	1.15	
Insurance	1 50	2 54	1 26	2.10	.86	.50	1.47	
Garage	1 00	1 20	1.00	1 00	89	1 00	1 01	
Maintenance	50	.	.50		1 00		75	
Overhaul	1 33	2 75	1 80	1 60	2 00	3 00	2 07	
License	17	27	20	20	.20	.20	20	
Body upkeep	25	.	.30	.10	.40	...	27	
								10.69
Supervision	50	2 93	2 05	1 90		.	1 90	1.90
Lost Time	2 20		1 67	3 40	2 50	1.97	2.57	2.57
Total	$23 45	$28 09	$24 26	$27 07	$22 12	$24 17	..	$26.82

The figures as given apply particularly to operation of trucks in large fleets, such as those employed by the interurban haulage companies. They were furnished by companies operating out of New York City.

SOCIETY SERVICE

A Section Dealing with the Results of Teamwork by Technical Men

Kansas Engineering Society Advocates Standardized Fees

At the recent annual meeting of the Kansas Engineering Society great interest and activity among the members were manifest in connection with a more closely organized movement to improve the remuneration for engineering services. A resolution was passed providing for an appeal to the four great national societies and the Engineering Council, asking that they act in unity by (1) providing a practicable plan for the registration and proper classification, according to character of services, of all professional engineers and their assistants; (2) arranging a standard nomenclature to designate the various capacities in which engineers and their assistants serve; (3) adopting, after careful study, a scale of fees and of salaries for the young men of the profession, in such forms that it can be used by all local organizations of engineers throughout the nation in their efforts to secure a fair comparative compensation in accordance with the value of services rendered, and (4) providing a standing committee to coöperate with all local organizations of engineers in matters pertaining purely to compensation.

The Kansas Engineering Society, according to the resolution, pledges its allegiance and support to the national societies in the measures they may develop to supply these urgent needs for placing the profession of engineering on a proper plane of industrial equity.

Straw Ballots to Arouse Civic Interest

One of the methods used at the Feb. 7 meeting of the Chicago Chapter of the American Association of Engineers to awaken in its members a sense of their duties as citizens was a straw ballot on the five candidates seeking nomination in the mayoralty primaries. Five additional "yes-and-no" questions were answered as follows: Replies to the number of 121 favored political action along practical lines to further the objects for which the association was formed. One was against it. A unanimous vote was polled on the question: "Are you willing to pledge your support to the candidate for mayor of Chicago and for alderman in your ward who by his record and in his public utterances shows himself most favorable to the objects sought by our organization?" Of 115, 20 indicated that they were not registered voters, but 13 of these said they would try to register. Party affiliations indicated 80 Republicans, 26 Democrats, 3 Socialists and 9 independents.

Northwest Association Considers Technical Publicity

At its bimonthly meeting Jan. 28 the Northwest Association of Members of the American Society of Civil Engineers heard W. W. DeBerard, Western editor of *Engineering News-Record* in an address on "Technical Publicity," illustrated by lantern slides. In the discussion which followed C. W. Tubley, mechanical engineer, stated that until hearing the address he had never understood what could be accomplished by publicity, and that he was a convert to the idea. A leading consulting civil engineer, L. P. Wolff, proposed that the American Society should set aside $100,000 annually for publicity work, $50,000 to be paid to five writers to furnish engineering articles for the daily and Sunday papers, and the balance for expenses of inaugurating and maintaining the work. Another engineer spoke of the attitude of newspaper editors, saying that it was impossible to get reporters to write engineering articles in an intelligent manner and that it was also impossible to get engineers to do so from the newspaper man's point of view.

Minnesota Senator Asks Engineers' Help in Framing Drainage Bill

Frank statements were made by a Minnesota state senator who appeared before the St. Paul Engineers' Club, Jan. 24, to the effect that a proposed drainage bill drawn by an attorney had so many faults it should have been drawn by engineers in the first place. As

it was, he asked their assistance in amending the bill. This is being undertaken by a process of careful study and discussion, first at the club's regular meetings. The conclusions of these deliberations were referred to the Minnesota Surveyors and Engineers' Society meeting, Feb. 12-14. If unified action is secured, the whole matter will be put in the hands of the Minnesota Joint Engineering Board for presentation to the legislature. Thus all classes of engineers will have a chance to know how it may affect them.

This method of putting the same proposed legislation through these different organizations will tend to popularize the bill and arouse interest in it by a large number of engineers; also, the bill finally will go to the legislature in a form commanding unanimity of engineering opinion and from a body representing practically all the organized engineers of the state. It is an example of democratic society service to the public worthy of emulation elsewhere.

Duluth Engineers Recognize Public Service Responsibilities

Practically all organizations of engineers have based their constitutions on the idea of service to engineers and "the advancement of engineering knowledge and practice and the maintenance of a high professional standing among members." It is refreshing, therefore, to read the following from the constitution of the recently formed Duluth Engineers' Club. It indicates the awakening of the engineers in the Northwest to their civic responsibilities and to their duty of service to those members of the community outside of the profession:

"The name of this corporation shall be the Duluth Engineers' Club; its general purpose is to create an instrument by which united action can be obtained by the members of the engineering profession in Duluth and vicinity; to serve the community, state and nation better than in the past; to raise the standards of the profession and the ideals of the individual, to make the profession more worthy of consideration by the community; to awaken among engineers an interest in all civic matters in general, and particularly in regard to matters for which the engineer, because of his training, should feel a peculiar civic responsibility; to make the community aware of the service the engineering profession is prepared to render; to add to the scientific knowledge relating to engineering; to increase social intercourse between members of the profession, and in general for uplift of the community, the profession and the individual."

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Deterioration of Burlap in Waterproofing

Sir—The writer read with considerable interest the letter in your issue of Feb. 6, 1919, from A. H. Rhett, commenting on an article by H. T. Welty, engineer of structures of the New York Central R.R., published in your issue of Dec. 12, 1918, p. 1081. The instance given of the successful use of a single layer of untreated burlap is interesting, but "one swallow does not make a summer." I do not think that Mr. Rhett carried the chemical investigation of the destruction of burlap in a waterproofing course sufficiently far to reach the correct conclusion.

It is undeniably true that there is a marked percentage of sulphur in coal-tar pitch and a lesser percentage in asphalt, and it is also conceivable that this sulphur reacted, to some extent, against burlap. However, the presence of a sulphur content in asphalt or coal-tar pitch is not the reason why burlap should be excluded from a waterproofing system, nor is it the reason why a cotton fabric is considered by engineers, generally, as the preferable membrane.

Reference to any standard work on industrial organic chemistry will show that burlap is chemically a combination of lignin and cellulose chemicals; that it is the most perishable of all vegetable fibers; that even the small amount of moisture in the air will cause it to deteriorate very rapidly, and, finally, that this rate of deterioration is greatly increased where the moisture carries alkali. Inasmuch as the waterproofing is to be placed on an alkali surface and is to be covered over with a body of alkali materials, all water which reaches the waterproofing course must contain alkali, and if a pinhole is left in the top swabbing of the waterproofing agent, water will reach the burlap and, as the latter is intensely hygroscopic, will be drawn indefinitely through the blanket, rotting large sections.

There appears to be also a serious misunderstanding as to the object in saturating a waterproofing membrane. It is not, as Mr. Rhett asserts, for the purpose of securing a thorough bond between the fabric and the compound. Inasmuch as burlap with its wide-open mesh will permit the ready passage of compound through the fabric and the consequent sealing of one layer with another through the open mesh, it is possible to secure a good bond in the blanket as a whole and consequent compactness. The object of saturation is, entirely, preservation; so that if, as is very apt to happen in practice, an imperfection is left in the final swabbing coat whereby water can reach the membrane directly, the membrane will be protected from rot or from the lateral translation of water by capillary attraction.

To refer back to the most frequent cause of the deterioration of burlap in a waterproofing blanket, we find that the burlap fiber is naturally extremely brittle. In its manufacture into yarn, to be subsequently woven into fabric, this fiber is treated by long immersion in a combination of oils, consisting of a small percentage of sperm oil, the balance being the cheaper vegetable oils indigenous to the Far East. When the burlap fiber, through this treatment, has become thoroughly impregnated with these oils, the oils are squeezed out and the fiber is turned into yarn and subsequently into fabric. These oils are a solvent for both coal-tar pitch and asphalt. Moreover, they are volatile. When the

hot compounds are applied to the burlap, part of the oil is volatilized and what remains is gradually, through the processes of time, absorbed by the waterproofing compound. The burlap is thus reduced to its original condition of extreme weakness and great fragility.

For these reasons the writer is convinced that Mr. Welty is absolutely correct both theoretically and practically in advocating the use of a cotton fabric, as against one made of jute. J. B. W. GARDINER.

No. 18 E. 41 St., New York City.

How Building Is Promoted in Huntington

Sir—In connection with the articles you have been publishing on methods of encouraging building, I would like to outline the scheme, which we call the "Huntington, Ind., Plan," that has proved successful in this city. As a testimonial to the workings of the plan, I might say that statistics showed that in Huntington, a city of 20,000 population, there were more new houses built last year, in proportion to the population, than in any other city in Indiana.

One year ago several of our progressive builders, supply dealers and lumbermen organized what we called the Huntington Community Development Club. The organization was made up of the lumber dealers, building-supply dealers, hardware merchants, plumbers, electrical contractors, sheet-metal contractors, furnace dealers, furniture dealers; in fact, any class of people in our community who were interested in the sale of material entering into the building of a modern home. We elected a president, secretary and treasurer and an advertising committee. Our plan was to have each member subscribe a small amount toward a fund to be used for educating our people to the fact that they should build homes now. We used full-page space in our two daily papers, and the result, we are confident, was that we encouraged a great many people to build homes, which were badly needed in our city at that time and are still just as badly needed.

The plan worked out so well and we had so good a reputation last year that we have reorganized our committee again this year and have added a number of other firms to our list, including real estate dealers and building contractors, such as carpenters, masons and cement contractors. In raising our fund we have no amount larger than \$25 and nothing less than \$10. This gives us a fund of between \$500 and \$600, which we will invest in full-page space in our two daily papers. You can readily see that this is a very small expense to any one of the firms interested, but on the whole it will amount to fine publicity in increasing the interest in building conditions in our own locality.

The advertisements refer simply to general building conditions, and do not advertise any one particular commodity. We had some mighty fine "copy" in our last year's campaign, and I think we could furnish anyone who would be interested with duplicates of our "copy" if any would care to adopt the same plan. Furthermore, if any of your readers wish to go into this matter and adopt the Huntington plan and will correspond with me, I shall be very glad to put them on a mailing list and send them copies of our local papers as our advertisements appear.

I am confident that if all of the smaller cities would adopt this plan, which would not be a very expensive one owing to the small rate for advertising space in cities of this size, we would create a great deal of interest throughout the United States and encourage a great deal more building than would be possible if the attention of the people were not called to it through a sane and careful advertising campaign.

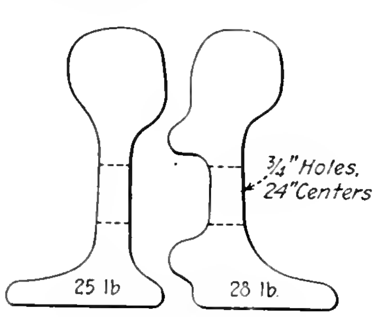
J. M. TRIGGS,
The Majestic Company.

Huntington, Ind.

Finds Peculiar Old Railroad Rails

Sir—I am inclosing a drawing of a section of compound rail found in the vicinity of Camp Sherman, Ohio. In making a topographical survey of the surrounding country I found the rail shown in the right-hand sketch. It was 16 ft. long, not very badly corroded, but had the heaviest fish tails on the outside of the head I ever saw on a rail. No one recognized it as part of a rail, and I did not think of it as such until I found, on another farm, the rail represented by the left-hand sketch. This rail was also 16 ft. long. Both rails have evidence of small fish tails on the inside of the head. The material of which the two rails are made is wrought iron. None of the oldest inhabitants know when this rail was used. The B. & O. Southwestern is in this vicinity and the Marietta & Cincinnati, its predecessor, was one of the first railroads in Ohio. S. P. BAIRD.

Columbus, Ohio.



OLD COMPOUND RAIL SECTIONS

Criticises Details at Support of Pony Span in Cantilever Bridge

Sir—The rôle of critic is not an enviable one, but the urge that impels a man to want to see progress in his profession is one that is hard to resist. The writer believes that criticism pointing out errors in design that may spell failure of a structure is eminently constructive criticism. One of the most vital essentials of safe design is a proper regard for details. I have many times called attention publicly to common errors of steel structural detail designing. Some of the very errors that I have emphasized are exhibited in an article in your issue of Jan. 16, p. 143, on the Willamette River bridge at Salem, Oregon.

One of the errors referred to, or a nest of them, is at the support of the pony span. In the first place, the line of reaction of the rocker shoe is apparently about 9 in. away from the intersection of the members supporting it. This means that a tremendous bending moment must be carried by these members. The next fault is that the upper one of the two members just referred to has a sharp bend where it has its full stress. By no law of mechanics should a structural member be expected to take its full stress around a bend. Bends should only be employed where there is a properly detailed member to take the resultant stress at the bend.

The other error in this detail is in the lack of adequate support under the rocker shoe. There is a load here which I estimate roughly to be 130,000 lb. for dead load only. There are no stiffeners under the seat of the shoe and a very few rivets under it. The center of gravity of the group of rivets connecting the supporting angles is a wide distance from the center line of the rocker shoe, which means heavy eccentric stress on the rivets. Judging from the number of rivets in the other ends of these members no excess of rivets has been put in to take care of this. On the face of it, the supporting of this heavy load on the feather-edge of these two members, so to speak, is not proper design.

The next fault in details is in the sidewalk bracket in the half cross-section of the deck span. The tension of the upper member of this bracket produces twisting on the top chord of the truss, or, in other words, this tension is not provided for. There ought to be a connection to the top flange of the floorbeam. The bottom member of this same bracket is bent (in the connection plate) where it has its full stress. There is no provision to take the "kick."

The sidewalk bracket shown in the half section of the pony span is also faulty in its connection to the truss. This connection, so far as the drawing shows, is by means of a pair of angles giving excessive tension on the rivet heads, and there is no diaphragm or other member to take the top-flange tension into the floorbeam.

This designer is not alone in these errors. They are all too common. It is for this reason that they ought publicly to be emphasized. EDWARD GODFREY.

Pittsburgh, Penn.

International Language for Modern Engineers

Sir—I have read with much interest the letter in your issue of Jan. 16, p. 156, entitled "International Language for Modern Engineers" and advocating Esperanto as a study for engineers. I hope other engineers will follow it with like recommendations, for I believe there are many in this country who are heartily in sympathy with this idea of using an international language. I note, for instance, that Henry W. Fisher, chief engineer of the Standard Underground Cable Co., is an enthusiastic Esperantist, also that William L. Church, one of the founders of Westinghouse Church Kerr & Co., is another.

The signs of the times point to a steady growth of the use of Esperanto. I know of a $50,000 contract obtained in connection with a reinforced-concrete undertaking that came about through Esperanto. The introduction of Esperanto as a regular feature in the school courses is making decided headway in England; while especially valuable is the testimony that it helps in the study of other languages.

This means that if you would learn to speak Spanish—a year's study—you would make more headway by spending the first three months on Esperanto in order to gain a general language sense than by devoting the entire 12 months to Spanish alone. This argument of Esperanto as a basis for language study bids fair to find general acceptance among the very many who, because they are accomplished in one or more foreign languages, would like to sidetrack any effort to supplant foreign-language study by this international medium.

"Free Masonry for a dollar a year" is an argument with strong appeal. Learn the language and buy an Esperanto directory for a dollar; look up the Esperanto consuls who officially represent the language here, there and everywhere, and see if in traveling for business or pleasure, or even in writing for information, you do not find a hospitality that cannot be estimated in dollars and cents. Experience has shown that the Esperantist, thus using his directory, finds he has friends and information bureaus the world over.

As chairman of the propaganda committee of the Esperanto Association of North America, I am too prejudiced to give much advice. Rather let the advice come from people who are disinterested. I have been at it 12 years and have found my interest steadfast.

G. W. LEE,

Boston, Mass. Librarian, Stone & Webster.

Heavy Counterweight Tested According To Assumptions

Sir—In reference to the article "Proportion Concrete to Weigh 173 lb. per Cubic Foot," in *Engineering News-Record*, of Dec. 26, 1918, p. 1187, attention is called to the following test of an extra-heavy concrete counterweight, in which the added weight was gained by the use of punchings.

The proportions and weights per cubic foot of the materials were:

Cement	0.172 cu.ft. at	94 lb. =	16 lb.
Sand	0.515 cu.ft. at	95 lb. =	49 lb.
Aggregate	0.86 cu.ft.		
1. Stone	(0.36 x 0.86) cu.ft. at	98 lb. =	31 lb.
2. Punchings	(0.64 x 0.86) cu.ft. at	266 lb. =	146 lb.
Total			242 lb.

With 9 lb. water these weights make 1 cu.ft. of concrete exactly. In the test the weights of the cube were as follows:

Weight day of test	247 lb.
Weight 3 days after	243.5 lb.
Weight 10 days after	242 lb.

No loss in weight after this time.

C. C. NEHER.

United States Engineer Office, San Juan, P. R.

Alaskan Railroad Train Service Maintained Despite Icy Rails

Difficulties of railroad operation in Alaska are apparent from a note in the official weekly publication of the Alaskan Engineering Commission, which describes conditions between Mile 57 and Mile 68 early in December. Despite these adverse conditions service has not been discontinued. This section of the line is low and flat and is affected by the adjoining glaciers. Warm rains, followed by sudden cold weather, made about an inch of ice on the rails in this section and, there being no machinery to remove it, gangs of laborers at a temperature —12 F., worked continuously in relays Saturday, Saturday night, Sunday and Sunday night, picking the ice off the rails ahead of the trains. According to a later issue of the Alaska Railroad *Record* the operating department was not discouraged by this and other troubles along the line, through service being maintained even when dog teams had to be used to transfer mail and passengers across snow-filled gaps.

Hints for the Contractor

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Awning Reduces Lost Time by Hiding Movements of Derrick

COMPLAINT of an overhead cable tramway was made by the superintendent of a construction job because "the men stopped work to watch the loads go by." On another job a derrick periodically swung its load over the yard where a crew of carpenters was framing forms. A flimsy canvas awning had been stretched over the carpenters' benches. This covering was obviously no protection against falling objects, and no other purpose which it served could be observed. Curiosity prompted inquiry. "Until that awning was put up," replied the contractor, "those carpenters stopped work every time the derrick swung its load and stood ready to dodge if it let go. Now they can't see the load pass and they pay no attention to it. That awning saves 10% lost carpenters' time." Perhaps the saving was overestimated, but the contractor's action was prompted by sound reasoning. Any spectacular construction operation distracts to some extent the attention of every workman within sight of it. If the operation involves an element of danger, its attraction becomes almost irresistible. If in such cases the construction of a screen is practicable at small cost the investment will often be profitable.

Other Articles in This Issue of Interest to Contractors:

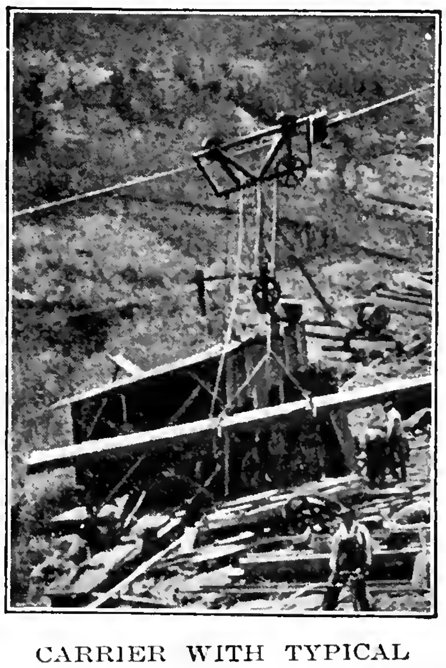
Home-Made Cableway Carrier Operates With Single Hauling Line

MATERIALS and equipment for the Gibraltar dam near Santa Barbara, Cal., had to be conveyed over a 750-ft. cableway from the end of the industrial railroad track to the dam site. A carrier was devised for this cableway by W. A. Kraner, of Bent Brothers and W. A. Kraner, contractors, and it is operated satisfactorily with a single hauling line. This is made possible by the fact that the cableway is on an incline sufficient to return the carrier by gravity, but there is also an ingenious arrangement of hooks which lock the carrier under certain conditions.

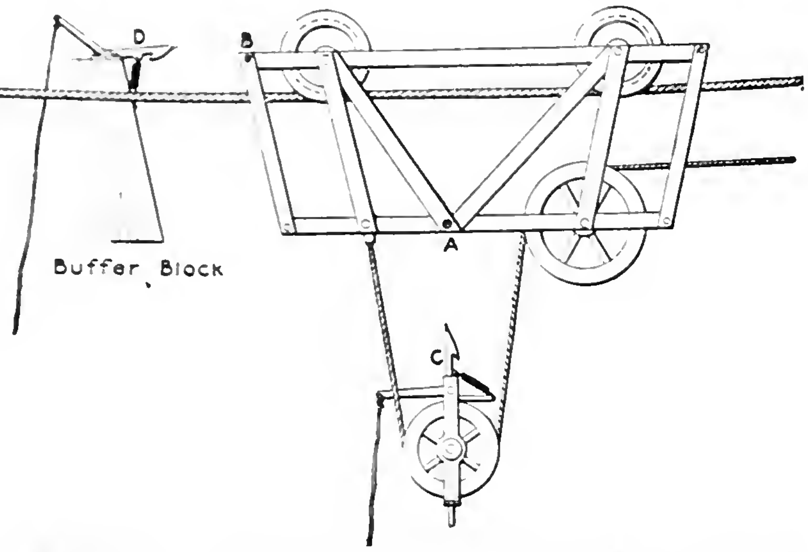
The carrier is made of heavy strap iron, and operates on a 1½-in. cable. Besides the two main cable wheels which support the frame there are only two other wheels on the carrier. One of these is an idler or guide sheave fixed to the carrier frame and around which the hauling line passes. The other is a sheave around which the hauling line also passes but which is attached to the counterweight and moves with the load to and from the carrier. The end of the ⅝-in. hauling line, after passing around the two sheaves, is attached to the carrier frame.

The interesting features of the carrier are the two hooks which lock automatically. One is attached to the sheave which moves up and down with the load; its function is to lock the load to the carrier so that it cannot come down until desired. The hook projects above the sheave in such a way that as the load is drawn up to the carrier the hook engages a bolt in the frame and is held in place by a steel spring. Thus, even though the hauling line is slacked off, the load would remain suspended from the hook. The hook can be disengaged from the bolt by a pull on the releasing rope which hangs down to the ground. This release can be effected only when the hauling line is taut; afterward, as the hauling line slacks away the load comes down from the carrier.

The second hook is attached to the buffer-block at the lower end of the cableway span. Its function is to engage a bolt in the carrier and hold it stationary on the main cable while the hauling line lifts the load and locks it to the carrier. After this has been accomplished the hauling line is slacked away slightly, and the hook in the buffer block is released by the pulling of a rope which hangs down to the ground. The load is then moved up the cableway by winding up the hauling line. A buffer-block hook is needed at the lower end of the cableway only because the incline of the main cable is not steep enough to cause the carrier to slide down from the upper end when the load is being lowered. However, if the cableway were steeper the addition of a hook in the upper buffer block could hold the carrier in the same way as



CARRIER WITH TYPICAL LOAD



HOME-MADE CABLEWAY CARRIER OPERATES WITH SINGLE HAULING LINE

Hooks C and D automatically engage pins A and B until released by trip ropes

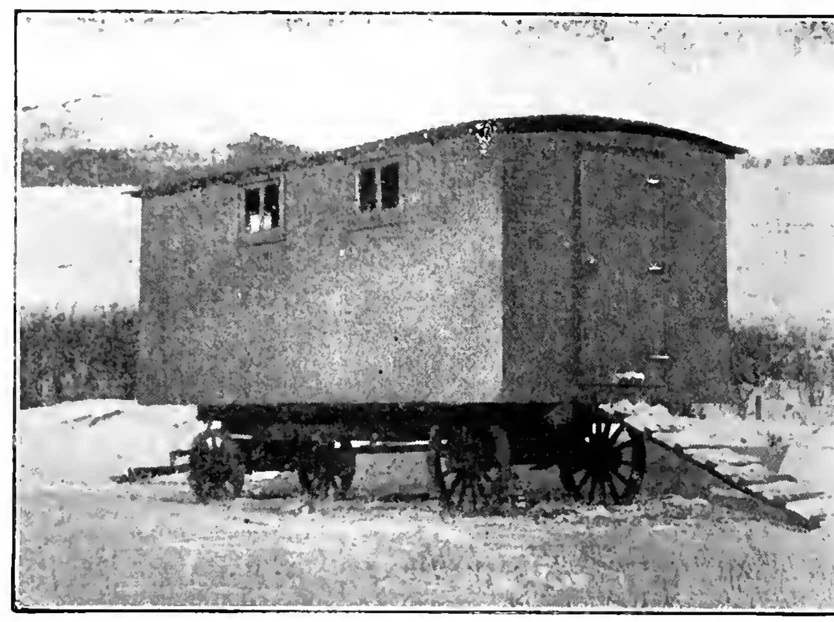
the one at the lower end, and the system would still be automatic. The carrier has given excellent service, it is reported, and has regularly handled 40-sack cars of cement with 6 min. to the round trip. Loads up to six tons have been hauled up with the 25-hp. motor installed for operating the cable.

Car Camps for Road Maintenance Gangs Repay Cost Each Season

CAR camps on wheels with a bunkhouse and mess-hall unit in each outfit repay their cost each season on road maintenance in Gogebic County, Michigan, by reducing lost time of men and wear and tear of camp equipment. An outfit, with a mess-hall unit complete, as illustrated, and an exactly similar bunkhouse unit without furnishings, was built by a local wagon maker for $675.

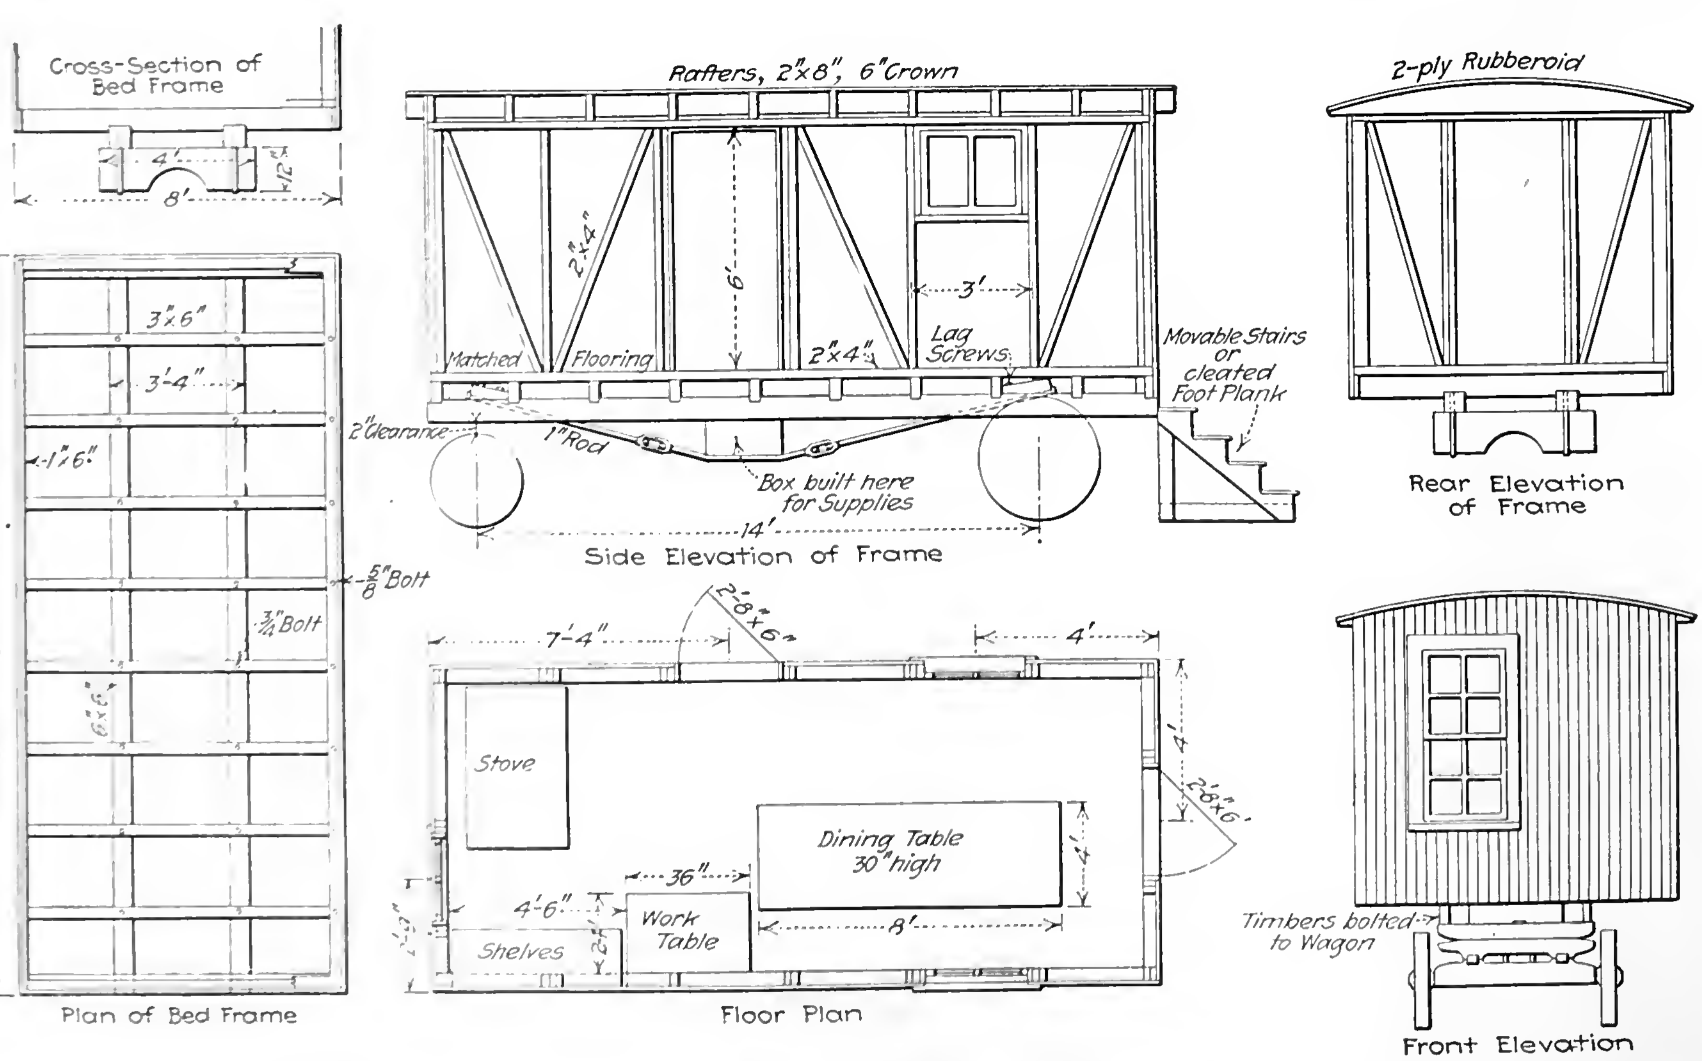
Roads in Gogebic County are long and run through a sparsely settled country. In summer the traffic is heavy. Maintenance, therefore, calls for continuous repairs over long stretches of road. One outfit last season kept a 70-mile road in shape, and the camp was at all times close to the repairs being done. The time lost traveling between camp and work was almost negligible.

The wagons are standard-gear, with $\frac{5}{8}$ x 4-in. tires, $3\frac{3}{4}$ x 12-in. skeins, 28-in. front wheels and 36-in. rear

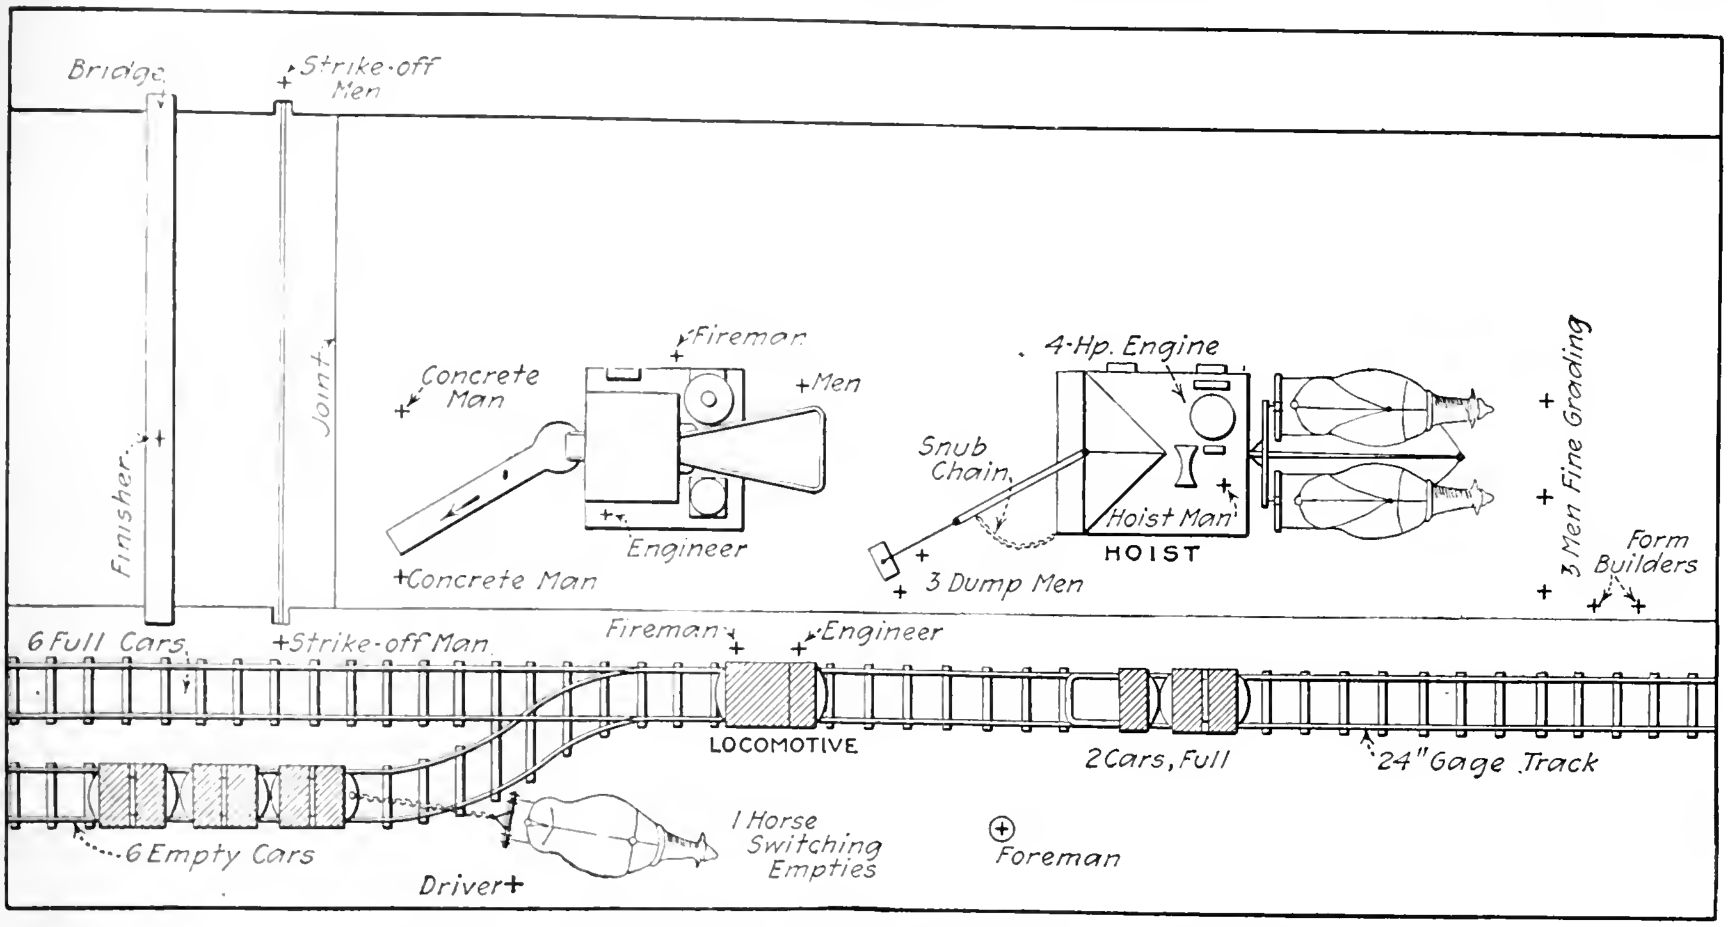


WAGON CAMP UNIT LOCKED AND LAID UP FOR WINTER

wheels. The bolsters are made as wide as possible; in this case they are 40 in., and the front bolster is so arranged that the front wheels can turn under the body as far as the reach. The construction of the wagon house is clearly shown by the drawings of the mess-hall unit. The bunkhouse unit is exactly similar in construction, but is furnished with steel cots. It will accommo-



DETAILS OF WAGON TOP FOR PORTABLE BUNKHOUSE AND MESS HALL ON ROAD REPAIR WORK



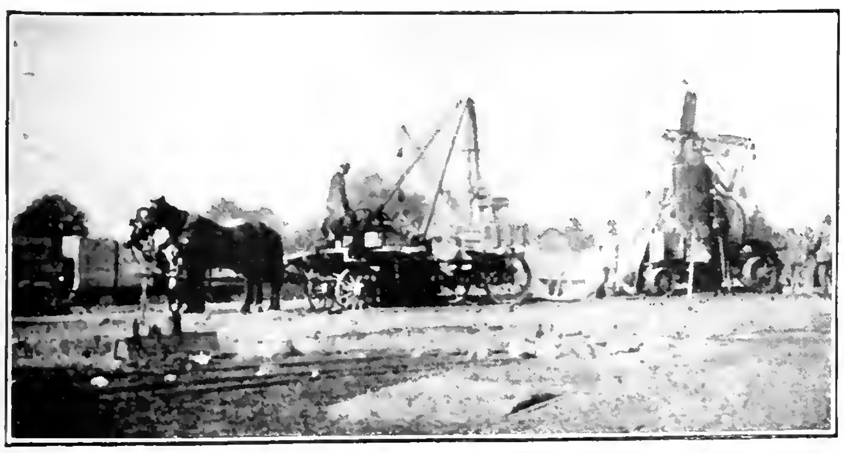
LOCATION OF EQUIPMENT AND WORKING FORCE AT MIXER

date cots for 12 men. A 7000-lb. tractor hauls each unit easily. C. F. Winkler, Bessemer, Mich., is the engineer of the board of road commissioners of Gogebic County.

Horse-Drawn Derrick Loads Concrete Mixer

PROPORTIONED batches hauled in buckets on industrial flat-cars were transferred to the mixer by a horse-drawn derrick, in constructing 5557 ft. of concrete road for the extension of Camp Custer. The concrete slab was 18 ft. wide, 8 in. thick at the center, and 6 in. thick at the edges. At intervals, opposite warehouses, the pavement was widened into aprons each 216 sq.yd. in area. One apron was a day's work for the paving gang; on straightaway pavement the maximum day's work was 330 lin.ft. or 660 square yards.

Aggregate brought in railway cars was unloaded by a clamshell into stock piles or elevated bins located about three-quarters of a mile from the job. Industrial flat-cars, each carrying two 120-cu.ft. bottom-dump boxes,



HORSE-HAULED DERRICK HANDLED BATCH BOXES

ran to the bins and received their charges of sand and gravel, then to the warehouse to take the cement, and finally, in five-car trains, were hauled to the mixer by a 3-ton gasoline locomotive. At the mixer the derrick with a 4-hp. gas engine lifted the boxes one at a time and dumped the batches into the mixer. The operations at the mixer are indicated by the drawing.

The Camp Custer extension was built under the direction of Maj. T. A. Leisen, constructing quartermaster, and Samuel A. Greeley, supervising engineer, by the W. E. Wood Co., Detroit, Mich., contractors. D. E. Marsh was division engineer of highway construction.

Extra Screening of Sand Reduces Concrete Costs

EXTRA screens and a sedimentation basin added to the gravel-washing plant at Lockington dam of the Miami Valley flood-protection works are saving $100 a day in the cost of concrete. The washing plant is the standard construction described in *Engineering News-Record* of Oct. 10, 1918, p. 680. At Lockington the sand, as it came from the regular ⅜-in. revolving screen, contained an overproportion of grains of larger size. To increase the fine-grain content of the sand produced, two stationary inclined screens of ¼- or ⅛-in. mesh have been placed underneath the revolving screen, and the water from the revolving screen, instead of being wasted, is led to a settling tank where the fine sand is dropped and the water escapes over a weir. At intervals the fine sand is shoveled from the tank into the sand bins.

By thus screening out the coarse grains and salvaging the fine grains, a concrete sand is being obtained which in lean concrete has reduced the cement required from six to five bags per batch, of 16⅔ per cent. In rich concrete the saving is proportionally greater.

The construction of the Lockington dam is under the direction of the Miami Conservancy District, Arthur E. Morgan, chief engineer, Charles H. Paul, assistant chief engineer, and C. H. Locher, construction manager. B. M. Jones is division engineer.

NEWS OF THE WEEK

New York, February 27, 1919

New Highway Bill Introduced in Congress

Federal Highway Commission and System To Be Established—Presented as Basis for Future Action

A new highway bill, which would establish a Federal highway commission to take charge of building and maintaining a United States highway system, has been introduced in Congress. In introducing the bill into the Senate (as S.5626) Senator Townsend stated that he did not contemplate asking for its passage at this session, but desired that it might be criticised by interested parties to furnish a basis for intelligent action by Congress at the next session

The bill provides for a commission of five members, to be appointed by the President, with the advice and consent of the Senate. Not more than three of the commissioners may be of the same political party, and they must be selected from various sections of the country. In appointing the first commissioners, the President shall designate each man's term as three, four, five, six or seven years, after which vacancies shall be filled for seven-year terms as they occur. The compensation of each commissioner shall be $10,000 per year, and the commissioners shall give their entire time to the work. They shall select a chairman from their number, and the commission is allowed to appoint a chief engineer and a secretary, and employ engineers, special experts, attorneys, clerks, etc., as they may be necessary. All other employees shall be obtained through the United States Civil Service Commission.

In defining the highway system the bill states: "There is hereby authorized to be established, constructed and maintained a system of highways . . . to comprise not less than two main trunk-line roads in each state and joining the national highway system in the adjacent states and countries." It includes necessary bridges, drainage structures, signs, guard rails, etc.

All Government highway agencies are taken over by the commission, and appropriations are provided for carrying on the work as follows: Fifty million dollars, available July 1, 1919; $75,000,000, July 1, 1920; $100,000,000 for each of the three next succeeding fiscal years, or $425,000,000 in all, which shall be available until expended. It is further provided that the Secretary of War, at his discretion, shall deliver to the commission without charge such vehicles, motor vehicles, road-building machinery, and other equipment as are suitable to construct and maintain highways. The Federal-aid law of 1916 is amended to allow wider scope in the interpretation of the words "post roads," and $25,000,000 each for the years 1919 and 1920 is appropriated for Federal aid.

After the general expenses authorized for the commission are deducted, the appropriations shall be divided as follows: One-third in the proportion of the area of the state to the total area of all the states; one-third in the proportion of the population of the state to the population of all the states, and one-third in the proportion of the mileage of highways in the state to the total mileage in all the states.

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Professional and Special Section, United States Employment Service; Thomas T. Read, manager Eastern zone, 16 East 42nd St., New York, and Ward R. Robinson, manager, Central and Western Zone, 63 E. Adams St., Chicago.

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

American Association of Engineers, F. H. Meyers, manager, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Federal-Aid Highway Appropriation Goes Through

Federal aid for highways received a large addition when the Post-Office appropriation bill went through the Senate carrying $200,000,000 for this purpose. The bill, which was noted in *Engineering News-Record* of Jan. 30, p. 251, now awaits the signature of the President.

The provisions of the bill greatly enlarge the scope of the term "rural post road" to cover roads that either are used or can be used for transportation of the mails. It also increases the maximum payments which the Federal Government can make per mile from the previous amount, $10,000, to $20,000. This will allow the building, in coöperation with the states, of roads costing $40,000 per mile.

Will Attempt to Bring About Lower Prices

Government Commission to Issue Fair Price Lists After Study of Each Commodity

Voluntary and general price reductions will, it is hoped, result from the operation of a new commission which has just been organized by the Department of Commerce in coöperation with the Council of National Defense. The scheme, which was proposed by Secretary of Commerce Redfield, does not involve any regulatory powers of the Government in price fixing, but is intended to bring about reductions in prices through coöperation of capital, labor and the Government and through wide publicity of what the Government considers fair prices.

The commission, known as the Industrial Board of the Department of Commerce, will meet with the representatives of each manufacturing interest and with the representatives of labor and will endeavor, through an adequate presentation of the underlying costs of the commodity involved, to ascertain what should be a fair price for it. This price it will announce with as much publicity as possible. There will be no obligation on any one either to pay or to accept such a price; it will merely be what the Government experts, after an analysis of the situation, consider to be a fair return for all parties involved. It is possible, however, that this price will become the basis for the Government's own purchases in the commodity.

It is hoped by this means to bring about that general, mutual and simultaneous reduction of reward, to all parties who profit by a sale, which is necessary to a gradual price reduction.

The board at present has for members George N. Peck, chairman; Hugh Frayne and Thomas C. Powell. Mr. Peck was vice-chairman of the War Industries Board. Mr. Frayne is a noted labor leader and its representative on the War Industries Board, and Mr. Powell is director of capital expenditures of the Railroad Administration. Three other members will be appointed.

Engineering Council in Annual Meeting Reviews Year's Work

At its second annual meeting in New York, Feb. 20, the Engineering Council voted to appoint a small committee to advise and confer with the Reconstruction Commission of the State of New York. This action was taken in response to a request from Abram I. Elkus, chairman of that commission, which request probably resulted from the letter sent by the Engineering Council to Governor Smith. The executive committee reported on the effect of the hearing called by the Engineering Council in regard to the sudden dismissal of 339 Public Service Commission engineers, and the fact that reinstatement followed. It was also decided to appoint a special committee to consider the classification and salaries of railway and Government engineer employees.

Among the many committee reports one of the most important was that of the Engineering Societies' Employment Bureau, which up to Feb. 15 had 1400 applications for positions and found positions for 200, and to which the national societies have agreed to give larger appropriations.

The new representatives in the Engineering Council are: A. N. Talbot, past president of the American Society of Civil Engineers; J. R. Worcester, consulting civil engineer, of Boston; M. E. Cooley, president of the American Society of Mechanical Engineers, and Albert Ladd Colby, of South Bethlehem, Penn., representing the American Society for Testing Materials. The other members whose terms expired were reelected. The total number in the council is now 26.

The new officers are: Vice-chairman, E. S. Jacobus, advisory engineer, Babcock & Wilcox Co.; C. S. Churchill, second vice-chairman, vice-president of the Norfolk & Western R.R. The additional members of the executive committee are Comfort A. Adams, president of the American Institute of Electrical Engineers; Philip N. Moore, past president of the American Institute of Mining Engineers; Charles E. Skinner, engineer of the research division, Westinghouse Electric & Mfg. Co. J. Parke Channing and A. D. Flinn were reelected chairman and secretary, respectively.

Freight Increase in Road Materials Not Contemplated

Recent rumors of a horizontal increase of 30% in freight rates, applying to sand, gravel, crushed stone and slag, are without foundation, according to the Division of Public Works and Construction Development, Department of Labor. Considerable highway construction and other contract work have been held up by the uncertainty, and should now go forward. The Division of Public Works investigated the rumor and was assured by the Railroad Administration that no such raise is contemplated. If these rates are increased in the future, it will be as a part of a general rate increase, which is not proposed at the present time, as shown by the following circular of the Railroad Administration, dated Jan. 20:

"There is no foundation for the report that the Railroad Administration has given, or is giving, any consideration to any increase in the present basis of rates."

President Invites Local Officials To Discuss Reconstruction

Governors of the states and mayors of over 100 cities have been invited to attend a conference at the White House Mar. 3-4 to discuss "vital questions affecting business and labor." The President will address the conference. The Department of Labor, which is promoting the meeting, issued the following statement:

"The conference will take up vital questions affecting business and labor. It is the desire of the President to establish before he returns to Europe a definite nation-wide policy to stimulate public and private construction and industry in general. A large number of officials have already signified their willingness to attend such a conference. Plans will be presented to show that the Federal Government is anxious to coöperate with the various states and municipalities in all efforts to assure continued prosperity in the interests of manufacturers, merchants and wage-workers."

Society Gets Mayoralty Candidates' Promise to Aid Engineers

The five contestants for mayor in the primary election in the City of Chicago, Feb. 25, all answered in the affirmative the following questions put to them by the Chicago Chapter of the American Association of Engineers: "Will you, if elected, fairly investigate the claims of the engineers working for the city to more adequate remuneration?" (The rates have not been changed in 21 years). "Will you appoint no 60-day men without engineering experience to engineering positions?"

Water-Works Improvements for Seattle Authorized

The city council of Seattle has authorized a transfer of $750,000 from the Skagit River hydro-electric fund to the water-works fund for three dams at Swan Lake, and for conduit construction. The Board of Public Works is busy with plans and specifications. The lake will be raised from El. 468 to El. 488, creating a total storage of nearly 80,000,000,000 gal., of which almost 50,000,000,000 gal. will be available through an outlet at El. 455. A 2½-mile tunnel will be driven from the lake to Molasses Creek, and a pipe line will be built from the creek to the city. L. B. Youngs is superintendent of water-works.

Transmississippi Readjustment Congress at Omaha

Some 1200 delegates from 204 cities and towns in 22 states held a Transmississippi Readjustment Congress in Omaha Feb. 19-20.

City officials who attended a section meeting agreed that public improvements should be made without waiting for a fall in prices of labor and materials. The keynote of the section meeting of the contractors and builders was that "the way to resume building operations is to resume." Several speakers were of the opinion that there would be no material fall in prices for months to come. John W. Towle, of Omaha, said, "We should go ahead for the next few months and do business on a very slight margin of profits, or no profits at all."

Resolutions were adopted indorsing the principle of a league of nations; the promotion of public and private work by Federal, state and municipal governments during the readjustment period; Federal reclamation of arid and waste lands in the public domain and the enactment of state laws "whereby the returning soldiers may be given employment in the preparation of such lands for settlement and provided with assistance to make permanent homes when the reconstruction period is passed"; the construction of good roads by Federal, state and local coöperation; partnership instead of enmity between capital and labor; the return of the railroads to their owners, with Government regulation to "prevent the abuses of the past and secure to the public the greatest good to be derived from economic, efficient, coöperative management, eliminating restrictive legislation that has hitherto hampered much-needed improvement"; the development of inland waterways, particularly the Mississippi and its tributaries, the extension of foreign trade and the turning over to private ownership of vessels built by the United States Shipping Board; legislation for "the early development of the water power now going to waste on the public domain," and giving to the people of the West the same right to develop their natural resources as "has already been exercised by the people of the Eastern states"; a Federal budget system; and "the extension of the Americanization campaign so as to include all portions of the country in which foreign influence still prevails."

American Institute of Consulting Engineers Elects Officers

The American Institute of Consulting Engineers elected the following officers at its recent annual meeting: President, L. B. Stillwell, reëlected; vice-president, A. M. Hunt; secretary and treasurer, F. A. Molitor. The following members of council were elected to replace those retiring: S. Whinery, Desmond FitzGerald, and J. Parke Channing.

Sacramento Flood Damage Increases

Heavy rains early in February caused a rise in the Sacramento River sufficient to inundate some 10,000 to 15,000 acres of farm land in the Sutter Basin district south of Marysville, Cal. The continued reclamation of areas along this stream has decreased the local storage capacity so that floods which a few years ago would not have caused material damage are now sufficient to submerge farms that have been heretofore above even the higher flood levels.

The extensive damage of the present flood is thought to be in large measure due to the fact that the west levee of the district was built before the east levee was closed, work being continued meanwhile on the Armour project, known as Reclamation District 1500. A large number of farmers have been flooded out, and the value of the crops lost is estimated to be between $500,000 and $1,000,000. Draining the inundated areas may require cutting the levee at the lower end of the district, and this cannot be done until the river subsides from the present flood stage.

The flood control in the Sutter Basin district is closely identified with the Sutter bypass project, and it has been understood in the court procedure attendant upon the work thus far that temporary inconvenience could be expected during the construction period.

Outlines Policies of American Association of Engineers

President W. H. Finley addressed an open meeting of the American Association of Engineers in New York City on the evening of Feb. 10, following a dinner of the New York chapter in his honor.

In referring to the great change of conditions in the engineering profession during the past quarter century, he pointed out that the schools are now turning out engineers in shoals, and that the profession has hardly found itself yet, but that it is clearly necessary for engineers to associate for the protection of their business relations to the community. The American Association, organized as a business association of engineers, he said, has no desire to take up technical matters, but is willing to leave that to the established societies. Its scheme of organization is to leave the development task to the local chapters, which should be free to work out their destiny without feeling the heavy hand of the national organization extended over them.

Following Mr. Finley, R. S. Parsons, chief engineer of the Erie Railroad Co., spoke entertainingly of the specific mental qualities that characterize the engineer, and of the relationship between these qualities and the ability to direct affairs efficiently. He made an earnest plea for greater participation of engineers in politics and administration.

Secretary of Associated General Contractors of America

G. W. Buchholz, who has been selected as acting secretary of the Associated General Contractors of America, as mentioned in these columns last week, p. 398, has been engaged in general contracting since his graduation from Columbia University, in civil engineering, in 1901. His service has been principally with the Snare & Triest Co. and the North-Eastern Construction Co., both of New York. He has acted in a wide variety of positions both in the field and in the office.

During his connection with the Snare & Triest Co. he was in intimate contact with the following works: The Government coaling station at Frenchman's Bay, Maine; terminal improvement, Williamsburg bridge, New York; Lackawanna Railroad Terminal at Hoboken, N. J., and the Delancey Street subway connection to the Williamsburg bridge. Later he served as works manager of the company's pier work in New York harbor and had charge of the construction of city pier 30, South Brooklyn, N. Y.; Pier 3, Erie Basin; Pier 17, North River, and Pier 8, Weehawken, Erie Railroad.

Chosen to Act as Secretary of General Contractors' Association

G. W. BUCHHOLZ

Shortly after the declaration of war against Germany, Mr. Buchholz was placed in charge of the construction of 36 fire-resisting ammunition-storage buildings for the Navy Department at Lake Denmark, N. J., and Iona Island, N. Y., including the necessary railroad construction to serve them. On Mar. 1, 1918, he joined the forces of Fred T. Ley & Co., Inc., of New York and Springfield, and went to Perryville, Md. as assistant works manager on a contract to construct an ammonium nitrate plant for the Bureau of Ordnance, Atlas Power Co. agents. He later became works manager of this $13,000,000 operation.

William A. Davis, selected to act as organization manager, to assist Mr. Buchholz, was recently connected with the War Labor Board and has been connected with the organizing of the National Association of Manufacturers, the National Association of Marble Dealers and the National Association of Steam and Hot Water Fitters. The association has taken offices in the Conway Bldg., 111 W. Washington Street, Chicago, Ill., which will be its headquarters, with a branch office in New York at 225 Fifth Ave., until May 1.

Navy Sells Material By Bids

Such surplus material as the Navy Department has will be sold through the usual sealed bids and not by a sales organization such as has been organized in the War Department. The amount of Navy surplus, however, is very small compared to that of the Army.

England Will Subsidize Home Building

Dispatches from England state that the British Reconstruction Ministry has offered to rebate 75% on the loss on homes built now if the property has decreased in value at the end of five years.

ENGINEERING SOCIETIES

Calendar

Annual Meetings

AMERICAN RAILWAY ENGINEERING ASSOCIATION; 910 Michigan Ave., Chicago; Mar. 18-20; Chicago.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

NATIONAL FIRE PROTECTION ASSOCIATION; 87 Milk St., Boston, Mass.; May 6-8, Ottawa, Can.

The Detroit Engineering Society held a meeting Feb. 21 which was devoted to a discussion of the measurement of the flow of liquids and gases by means of the Pitot tube. L. D. Royer, power and construction department, Ford Motor Co., delivered the address. The meeting was held jointly with the Michigan Chapter of the American Society of Heating and Ventilating Engineers.

The Michigan Engineering Society will hold a special meeting at Ann Arbor Feb. 28 for the purpose of reorganizing.

The Montreal Branch of the Engineering Institute of Canada will be addressed Mar. 6 by N. M. Campbell, who will speak on "Air Drills," and by Dr. Howard Bronson, who will read a

paper on "The Halifax Explosion from a Chemist's and Physicist's Viewpoint." A motion picture of "Burroughs Adding Machines," by the Burroughs Adding Machine Co., will be shown.

The Rochester Engineering Society will hold a meeting Feb. 28 at which Samuel W. Miller, president of the Rochester Welding Works, will speak on "Heat Treatment of Steel."

The Engineers' Club of Baltimore was addressed by C. J. Blanchard of the United States Reclamation Service at a recent meeting. Mr. Blanchard spoke on the work being done by the Government in reclaiming 2,000,000 acres and the establishment of homes for 3500 families, in the light of the plan of the Department of the Interior for returned soldiers.

The San Francisco Association of Members of the American Society of Civil Engineers held a special meeting Feb. 12, which was addressed by Maj. John D. Galloway, past president of the association, just returned from more than a year's service in France. Major Galloway was on duty at General Headquarters of the Army in the Intelligence Section, and gave an interesting illustrated talk on the information obtained from the enemy about troop movements and location and capacity of transportation facilities. He also showed a series of charts with which he reviewed the progress and important elements of the chief battles of 1918.

The Engineers' Club of Trenton Feb. 24 inspected the works of the Mercer Automobile Co. An opportunity was afforded by the automobile company for the inspection of every detail of the manufacturing process.

The National Fire Protection Association will hold its 23rd annual meeting May 6-8 in Ottawa, Ont.

The Cleveland Engineering Society was addressed Feb. 18 by J. C. Beardsley, Thompson Meter Co., New York, who read a paper on "The History of Water-Supply."

The Albany Society of Civil Engineers held a meeting Feb. 25 at which Col. C. G. Mettler, U. S. A., spoke on "Making Cannon at the Watervliet Arsenal."

The Engineers' Club of Philadelphia will hold a regular meeting Mar. 13. Dr. John A. Brashear will present an illustrated paper entitled "An Evening's Journey Among the Stars." On Mar. 12 the club will hold a special meeting, which will be addressed by Prof. Warren P. Laird, of the department of architecture, University of Pennsylvania, who will present an illustrated paper on "The Placement of the Delaware River Bridge." Professor Laird's paper will deal exclusively with the problem of the location of the bridge as a public utility, without going into matters of construction and finance. At the weekly luncheon Mar. 4 Alfred D. Flynn, secretary of the Engineering Council, will speak on "Joint Activities of Engineers; a Résumé of the Work of the Engineering Council and the Engineering Foundation."

The Nebraska Engineering Society will hold its annual meeting at the University of Nebraska, at Lincoln, Mar. 11. It will consider bills presented by its legislative committee to the present legislature designed to improve the position of the county surveyor by establishing as "official" only surveys made by county surveyors, state surveyors and Government surveyors. It will also consider the engineers' license bill, motor-vehicle license bill, state highway system bill and the one-mill state-aid road fund. In connection with this meeting there will be held the second annual Nebraska Road Institute, at the University, Mar. 10-14. The subjects will include the new road laws, road construction and road surveys. A visit will be paid to the Lancaster County roads now being built. Clark E. Mickey, University of Nebraska, is president of the Nebraska Engineering Society and chairman of the Nebraska Road Institute.

The Seattle Association of Members of the American Society of Civil Engineers elected the following officers at the recent annual meeting: President, L. M. Grant; vice-president, John L. Hall; secretary and treasurer, Philip A. Franklin.

The Duluth Engineers' Club passed a resolution, at its monthly meeting Feb. 20, authorizing the president of the club to appoint a civic relations committee of six members for the purpose of taking an active part in municipal projects. A resolution was passed in favor of the proposed appropriation of $50,000 a year by the State of Minnesota to complete the topographical survey.

The Pittsburgh Chapter of the American Association of Engineers has elected the following officers for the year: President, C. K. Harvey; vice-president, H. C. McCormack; secretary, H. Gellin.

Personal Notes

LIEUT. ARCH. W. NANCE has received his discharge from the Army and has returned to his work with the Farris Engineering Co., constructing engineers, Pittsburgh.

EDWARD R. BOWEN, formerly of the firm of Lippincott & Bowen, consulting engineers, has opened offices in the Central Building, Los Angeles, Cal., to specialize in water-supply and irrigation work.

CAPT. CHARLES A. FRENCH, Construction Division, U. S. A., has received his discharge from the service and has resumed his duties as city engineer and superintendent of public works of Laconia, N. H. He was in charge of utilities at the United States Army General Hospital No. 19, at Oteen, N. C.

COL. W. P. ANDERSON, C. M. G., C. E., chief engineer of the Canadian Department of Marine since 1891, is retiring from that position. He entered the service of the department in 1874. Colonel Anderson is a member of the Light House Board, which has recommended that his connection with that body be continued in view of his knowledge of navigable waters.

E. W. HAMMOND, division engineer, Buffalo, Rochester & Pittsburgh R.R., with headquarters at Du Bois, Penn., has been appointed city engineer of Summit, N. J., and will take office between now and the first of May.

GEORGE W. BORDEN, county engineer of Klickitat County, at Goldendale, Wash., has resigned to become construction engineer for Trout Lake Improvement District No. 3, recently organized to construct a concrete road from Trout Lake to White Salmon and Underwood.

MAJ. A. C. EVERHAM, Construction Division, U. S. A., has received his discharge from the service and has been appointed Western contract manager, Raymond Concrete Pile Co., with headquarters in Chicago.

CHARLES G. EDWARDS, assistant chief engineer of the Maryland Public Service Commission, has been appointed chief engineer, succeeding Charles G. Phelps, whose death was noted in *Engineering News-Record* of Dec. 26, 1918, p. 1203.

B. L. CROZIER has been appointed assistant engineer, Paving Commission of Baltimore.

LIEUT. JULIAN MONTGOMERY, U. S. A., formerly office engineer, Texas State Highway Department, has received his discharge from the service and has returned to the Highway Department as division engineer in charge of southern Texas.

WILLIAM F. STROUSE, Baltimore, has been appointed assistant chief engineer of the Maryland Public Service Commission, succeeding Charles G. Edwards, appointed chief engineer, as noted elsewhere.

CAPT. R. McC. BEANFIELD, topographical officer, Eighth Mounted Engineers, U. S. A., has received his discharge from the service and has entered the service of the Emergency Fleet Corporation as engineer, shipyard plants division, with headquarters in Philadelphia.

LIEUT. EDWARD T. JONES, Engineers, U. S. A., who was engaged in water-supply work on the staff of the chief engineer, Advanced Section, American Expeditionary Forces, has

returned to this country and has received his discharge from the service. He has resumed his duties as chief engineer, Stevens & Thompson Paper Co., Greenwich, N. Y.

LIEUT. JOHN MACMILLAN, Engineers, U. S. A., formerly city engineer of South Pasadena, Cal., who was recently discharged from the service, and C. R. SUMNER, consulting engineer of Los Angeles, have become associated as partners in the practice of civil engineering, with offices in the H. W. Hellman Building, Los Angeles.

LIEUT. COL. L. E. CURFMAN, 314th Engineers, 89th Division, has just returned from overseas and has resumed his former position as city engineer of Pittsburg, Kan.

LIEUT. HOMER G. OLMSTED, Engineers, U. S. A., formerly located at Camp A. A. Humphreys, Virginia, was recently discharged from the service, and has opened offices at Newkirk, Okla., for the practice of engineering, specializing in reports on oil properties.

LIEUT. JOHN T. CHILDS, Sanitary Corps, U. S. A., has been discharged from the service and has returned to his former position with the Rochester Bureau of Municipal Research, to continue his work in connection with the local sanitary services of street cleaning and collection.

CHARLES K. TUCKER, Morgantown, W. Va., has removed to Pittsburgh and has entered the office of the United States Engineer.

ALFRED M. BARRETT, Flushing, N. Y., has been appointed superintendent of highways of Queens County.

MAJ. H. M. MONTGOMERY, previously constructing quartermaster and disbursing officer at Government warehouses and waterworks at Jeffersonville, Ind., and the clothing warehouse at St. Louis, has received his discharge from the service and has become city engineer of Evanston, Ill.

E. N. FLOYD has been appointed supervisor of fire protection of the newly organized Bureau of Fire Prevention, Cleveland, Cincinnati, Chicago and St. Louis Ry., Cincinnati Northern R.R., and Louisville & Jeffersonville Birdge & Railroad.

LIEUT. W. H. FRANKLIN, Construction Division, U. S. A., has received his discharge from the service and has returned to the James Black Masonry & Contracting Co., of Seattle.

HENRY J. BURK, formerly county surveyor of Imperial County, California, has been appointed to the newly created position of city engineer of Holtville, Cal., to undertake surveys and the establishment of street lines and grades.

ALAN T. FRASER, district engineer, Western District, Canadian Northern Ry., previously division engineer at Edmonton, Alta., has been appointed chief engineer, Western Lines, Canadian Nationals Rys., with office at Winnipeg, Man. He was born in 1872 and was graduated from the School of Practical Science of Toronto in 1892, after which he entered railroad service as a rodman, later becoming assistant engineer. He served as resident engineer, Ontario & Rainy River Ry. at Port Arthur, Ont., and was also locating engineer for the Canadian Northern and assistant district engineer of the National Transcontinental before he became division engineer for the Canadian Northern.

JAMES B. HAYS, of F. C. Horn and James B. Hays, engineers and constructors, Boise, Idaho, will continue the business of the firm, following the death of Mr. Hays, noted elsewhere.

Civil Service Examinations

United States.—Superintendents of road construction, Bureau of Public Roads, Department of Agriculture, Mar. 25: Class A (candidates with four years' responsible charge of construction) $150 to $175 per month; Class B (six years' responsible charge) $185 to $225; Class C (eight years' responsible charge) $230 to $250 a month. Apply to United States Civil Service Commission, Washington, D. C., or to local office of commission for form 1312, and file before Mar. 25.

United States.—Assistant examiner, Patent Office, Washington, Mar. 26-28, and May 21-23 and July 23-25. Pay, $1500 per year. Apply to United States Civil Service Commission, Washington, D. C., or to any local office of commission for form 1312, to be filed in time to arrange for examination at place selected by applicant.

United States.—Chief physicist, qualified in aëronautics, National Advisory Committee for Aëronautics, Langley Field, Hampton, Va., Mar. 25, $3000 per year. Also physicist, $2100 per year. Apply to United States Civil Service Commission, Washington, D. C., or to any local office of commission for form 1312, to be filed before Mar. 25.

United States.—Senior highway bridge engineers, Apr. 1, Bureau of Public Roads, Department of Agriculture, Washington, D. C. Grade 1 (examination percentage above 70) $2400 to $2700 per year; Grade 2 (percentage above 80) $2800 to $3000 per year; Grade 3 (percentage above 90) $3100 to $3400 per year. Apply to United States Civil Service Commission, Washington, D. C., or to any local office of the commission for form 1312, to be filed before Apr. 1.

OBITUARY

RUFUS CAMERON HUNT, civil engineer and contractor, of Washington Court House, Ohio, died in Bowling Green, Ky., Feb. 18, at the age of 68. Mr. Hunt had been engaged in railroad work in this country and in China and South America since 1874, when he was employed by the Cumberland & Ohio R.R. A few years later he served as assistant engineer and resident engineer on contsruction work for the Cincinnati Southern Ry., and in 1881 became chief engineer of the Ohio Southern R.R., in charge of operating and construction work. From 1881 to 1891 he served as resident engineer and division engineer for the Louisville & Nashville R.R. and the Ohio River R.R. He afterward was employed as engineer for the Bessemer Iron & Steel Co., in charge of the construction of blast furnaces, and later went into the contracting business. After a brief employment with the Washington County R.R., Maine, as division engineer, he served two years in China as assistant engineer to William Barclay Parsons on the survey for 750 miles of railroad. During the following two years he was engaged as engineer and manager for the James P. McDonald Co. in mining and construction work in the Andes Mountains in Ecuador, Bolivia and Peru. Later he was connected with subway construction in New York City and with the construction of the Cumberland Mountain cutoff of the Baltimore & Ohio Railroad.

BRIG. GEN. JAMES F. MCINDOE, formerly colonel, Corps of Engineers, U. S. A., died in Tours, France, Feb. 6. He was born in 1868 and was graduated from West Point in 1891. For five years previous to 1913 he was stationed at Portland, Ore., with the rank of major, as United States engineer of the Portland District. In 1913 he was ordered to Manila, P. I., to assume charge of fortification construction, and was afterward transferred to Kansas City, Mo., where he was engaged in Missouri River work at the outbreak of the war.

F. C. HORN, of F. C. Horn and James B. Hays, engineers and constructors, Boise, Idaho, died Feb. 16, at the age of 57. In 1890 he was engaged in construction work in connection with the Chicago Drainage Canal project. He remained in the Chicago district until 1900, when he became assistant engineer on the construction of the Swan Falls power plant on the Snake River, Idaho. In 1905 he was employed by the United States Reclamation Service in the building of Minidoka dam and the Boise River dam.

RICHARD KEATINGE, for many years in the contracting business on the Pacific Coast, died at Los Altos, Cal., Feb. 13. His first connection with the contracting business was in the service of Ernest L. Ransome during the late '80's, from which time he was actively engaged in construction work in the West, erecting many of the concrete buildings in San Francisco. He had also been engaged in hydraulic work.

Shipping Board Reduces Cost of Tracings

Mechanical Reproductions Hard to Distinguish From Originals—Cost But Fraction of Latter

By means of a recently patented process, the Emergency Fleet Corporation has been producing, at a cost of from 10 to 13c. per square foot, tracings which, if made by hand, would ordinarily cost from $1.50 to $5 per square foot. The resulting tracings from this process are so nearly like the original that they are distinguishable as reproductions only on close inspection.

The accompanying table shows the amount of tracings delivered and the cost for the week of Dec. 5 to 12, 1918. A similar table submitted for the week of Oct. 17 to 24, 1918, shows 1137 sq.ft. at a cost of 12.9c per square foot. Besides the simple operation of reproducing tracings either on cloth or paper, the process has been used in a number of other ways and for a variety of purposes. It has been used for progress work, the reproductions, either on cloth or strong paper, being used instead of blueprints or Vandykes. It has also been used to produce new drawings, a large part of which are similar to those previously made, by blocking out the parts to be changed on either the transfer print or on the plate, with the new details drawn in by hand.

WEEKLY REPORT OF LITHO ROOM, DEC. 5-12, 1918

Number of men in room	2
Original tracings received	417
Process tracings made	1681
Number of plates of jelly poured	36
Number of square feet of tracing cloth used	2566
Number of square feet of tracing cloth delivered	2460
Number of square feet of tracing cloth wasted	106
Approximate Expense of Section for Seven Days	
Cost of tracing cloth	$137.25
Miscellaneous supplies and jelly	29.00
Supervision	60.00
Labor	46.00
Total Expense	$272.25
Approximate Cost per Square Foot	
Labor per square foot	$ .019
Materials and supervision	.093
Total Cost	$ .112

The work is done in the following manner: A matrix blueprint on a special transfer paper is made on any good blueprint apparatus, but it is not developed or washed before its use in the process.

When at the proper temperature a sensitized gelatine is pourned over a zinc plate, usually 42 x 98 in., or 42 x 110 in., which rests on an inclined, adjustable table, proper thickness of gelatine being obtained by the angle of inclination of the table and by the special pouring pot designed for the process. The overflow is caught and used again. As soon as the gelatine is poured, the table is righted and the gelatine allowed to set a few minutes.

From the adjustable table the gelatinized plate is put into a recess of a patented refrigerating table and undergoes the essential treatment on which the success of the process depends.

After a few minutes in the refrigerator the plate is placed, gelatine up, on the refrigerated top of the table, its temperature being maintained at the 60° limit of efficiency. The unwashed matrix print is laid face down on the gelatine for a few seconds, which, on removal, leaves the reversed image on the gelatine, a reaction having taken place between the unexposed lines of the transfer-print and the sensitized gelatine.

The gelatine plate is then inked with a squeegee roller spread with special carbon ink, which clings only to the lines left by the transfer-print reaction, being repelled by the rest of the gelatine.

The paper or cloth on which the tracing is desired is then laid smoothly on the gelatine, pressed flat and immediately taken off, the complete tracing being transferred to the finest line. As many as 10 to 15 impressions may be made on tracing cloth from one gelatine plate, merely by re-inking, and 40 to 60 copies reproduced on paper. The finished tracing is then complete, and can be used within a short time.

The time from the transfer print to the finished tracings was 30 min. or less. Pouring and refrigeration of plates are so controlled that no delay occurs at any stage of the process, and although the stated limit of capacity for a one-table plant is 500 sq.ft. a day, actual results, as shown by the table, have been greater than this.

New Locomotive Crane Developed by Construction Company

In the prosecution of heavy construction work, the Terry & Tench Co., Inc., of New York City, found it impossible during the recent emergency, to purchase in the open market hoisting and other machinery heavy and strong enough to answer the demands of the work they had on hand. They solved the problem by designing and manufacturing their own equipment. A locomotive crane is the latest product of this program.

After the needs and experience of the company were incorporated into the design of the various plants, their use in the field created a demand from other contractors in similar lines. To supply this demand, the Edward F. Terry Manufacturing Co. was organized and is building shipyard and locomotive cranes, steel derricks, erectors' tools, etc. This company, although associated with the Terry & Tench Co., does all of the manufacturing, the Terry & Tench Co. confining itself strictly to construction work. This will correct the impression given in *Engineering News-Record* of Jan. 16, 1919, pp. 136 and 137, in which it was stated that the traveling cranes described are of Terry & Tench manufacture.

The locomotive crane mentioned above carries out the results of experience on the work of the Terry & Tench Co. in a number of ways, among which are that all clutches of large size and of inside-band-brake type, and levers operating the clutches are balanced so that the mechanism is free from eccentricity and unbalanced thrusts, thereby making the work of shifting easy and reducing to a minimum the wear of these important parts. The turntable is prevented from tipping by the use of rollers bearing against the under side of the base ring, rather than by the center pin, as is the usual practice. The boom-hoisting drum is driven by means of a train of spur-and-bevel gears, eliminating the friction of the worm gear ordinarily used, so that the boom may easily be raised with full load on the hook. The boom-hoisting drum is equipped with an automatic holding and lowering brake of the inside-band-type, whereby the boom is positively held in position and is under complete control of the operator at all times, and the brakes for the main drums are so arranged that the speed of operation and safety are increased by means of a device which allows the load to be hoisted while the brake is set.

Business Notes

The W. L. Goeltz Co., Inc., engaged in industrial engineering and building, announces that on account of the increasing demand for its "Unit Construction" it is compelled to seek larger quarters. The company is now in its new offices at 150 Nassau St., New York City.

F. A. Putt, formerly with the Clyde Iron Works and the General Electric Co., has become manager of the equipment department of Edward Jobbins, Marquette Bldg., Chicago, handling railway, power and contractors' equipment and supplies.

The Barber Greene Co. of Aurora, Ill., announces the engagement of W. A. Buell, formerly conveyor engineer of the Goodyear Tire and Rubber Co., as sales engineer, and of H. W. Cudding, formerly general auditor of the Lyon Metallic Mfg. Co., as auditor.

The Con-Oil Tank Co. announces the opening of its Pittsburgh office, at 1215 Fulton Bldg., to facilitate the construction of concrete tanks in the Pittsburgh district. The company specializes in the construction of oil and water tanks.

The Wallace & Tiernan Co., Inc., 349 Broadway, New York City, manufacturer of "W. & T." chlorinating apparatus, has appointed David Morey, Jr., as its Southwestern representative with offices at 507 Scollard Building, Dallas, Tex.

Controlling and Using Colorado River Floods

FOR good or for evil, the possibilities of the Colorado River are great. Uncontrolled, that mighty stream may in any year surpass its ravages of the past and return the now fruitful Imperial Valley to a desert region—hopelessly irreclaimable should channel changes make irrigation impossible. With the river controlled, the future of the Imperial Valley will be insured and its possibilities increased. In addition, other areas may be made to produce bountiful crops, and vast water powers made possible. A storage project for achieving this, but with its more immediate aim to prevent floods and utilize water at and near Yuma, is outlined on p. 456 by one of the hydraulic engineers of the United States Geological Survey. His story compels interest. His closing plea for additional funds for more study of the Colorado problem deserves attention.

Making Supporters Through Committee Work

ONE of the wholesome signs in engineering society activities is the broadening of committee work. With the tendency to become interested in local civic affairs there is the inevitable consequence that committees on various civic activities will be appointed. These give opportunity for those who for a variety of reasons have abstained from service on technical committees. Thus, the interest in the society is broadened by bringing into activity a larger percentage of the society's membership. The same movement is in evidence in the Engineering Council. Its national service and licensing committees are composed of engineers widely scattered geographically. Moreover, they are not members of the council. One of the certain ways of making staunch supporters for an institution is to put inactive men to work.

Sound Practice in Bridge Detailing

BRIDGE engineers and detailers will be well repaid by a careful reading of Mr. Godfrey's letter to the editor in last week's issue, p. 441, and the reply by Mr. Metzger, published on p. 486 of this issue. One of the most important results of recording details of such bridges as that at Salem, Ore., here under discussion, lies in the constructive criticism thus developed. Mr. Godfrey has pointed out details considered to violate principles of sound engineering practice. Mr. Metzger would justify eccentric load application by "architectural requirements," and explain the use of bent members and connection plates virtually by appealing to the "factor of ignorance." Most engineers will agree that the joint detail at the rocker support of the pony span is an example of questionable practice. Whether or not an attempt was made to approximate to actual stress conditions in the several cases to which Mr. Godfrey refers, the lesson in this discussion for bridge detailers is plain: While mathematical analysis based upon fair fundamental assumptions can always be utilized for more or less exact knowledge of stress conditions, the best practice would avoid altogether details that involve eccentric loading or bring large torsional stresses to bear on bridge members.

Federal Government Has No Public-Works Policy

FOUR months after the armistice was signed, the President of the United States admits that the administration has no policy of reconstruction, in so far as that word applies to labor or public works. That is the only interpretation to be put upon Mr. Wilson's remarks to the Governors' and mayors' conference in Washington Mar. 3. "The primary duty of caring for our people in the intimate matters that we want to discuss here," he said, "falls upon the states and municipalities, and the function of the Federal Government is to draw the executive minds of the country together, so that they may profit by each other's suggestions and plans, and so that we may offer our services to coördinate their efforts in any way that they may deem it wise to coördinate." Clearly, this puts it up to the states, the counties and the cities. Public work must be started at once if the initial push to industrial activity is not to be delayed. Everyone seems agreed on this, but no one—or at least hardly anyone responsible—is doing much more than to accept it as a proper policy. When at this rather late day the Federal Government called together a conference of the Governors and mayors there seemed hope that some definite centralized scheme for action would be presented by which the states and cities might be encouraged to go ahead, and to go ahead immediately. Such a hope, apparently, is not to be realized. Instead, there is merely a continuance of the mild encouragement that has marked so much of the recent Department of Labor publicity bulletins, and optimistic expectation of some universal panacea arising from the conference. Whatever else the visiting mayors and Governors get out of the final two days of the meeting, they may be sure, after attending the first day, that they will have to go back home determined each to work out his own salvation.

Another Step Toward Society Coöperation

ANOTHER step and a long one toward uniting the engineering profession by coöperation between national and local engineering societies has been taken. The first advance was made last year, when the Cleveland Engineering Society adopted a plan for intermembership with the national engineering societies. Similar overtures were made soon after by the Engineers' Society of Western Pennsylvania. After a lapse of some months the American Society of Mechanical Engineers does itself and the profession the credit of meeting the local society proposition half way. Very properly, the first union of the mechanical engineers will be with the Cleveland Engineering Society. The elements of the plan are given on p. 495. It is not to be expected that the national societies will make similar arrangements immediately with all the local societies of the country, for in such departures it is best to make haste slowly, and in this particular case it will be necessary to weigh carefully the aims and accomplishments of each local society before according to it joint membership in the national societies.

Highway Builders in A. E. F. Needed Here

AN APPEAL that will get universal support in engineering and construction circles was made in a resolution passed last week at the convention of the American Road Builders' Association. It authorized the appointment of a committee to lay before the officials of the Government the urgent need, in the interest of highway work, to return to this country at once the road builders enlisted with the overseas forces. Highway departments and highway contractors' organizations throughout the country are short of experienced men. Under any war condition this would have been true, but the trouble is aggravated in the road-building field because of the strenuous campaign waged to get volunteers who were *competent to act as foremen and superintendents*, particularly for the Twenty-Third Engineers. It was set forth that pick and shovel workers were not wanted, but rather those who could direct work. Due to this appeal, a magnificent body of men was recruited. They are now sorely needed, particularly in view of the imminence of a heavy highway-construction program. Efficient handling of work depends on having an adequate force of men capable of directing operations. Therefore, highway engineers and contractors, deprived of the needed services of the men in the Army, should support the appeal of the road-builders' association, and urge upon the War Department the very great necessity of an immediate return of the road-building forces.

Nature Promotes Better Highways

SELDOM has there been such a swing of opinion away from earth roads as exists in Iowa today. The Governor has turned around completely, and is now an ardent advocate for hard surfaces. Nature, not to be outdone, has this year been so prodigal with heat units that the dirt roads during the winter have been practically impassable. Light graveled roads have been cut through, and under heavy hauling the best gravel has shown signs of utter destruction. Commenting on the situation, the *Service Bulletin* of the Iowa Highway Commission says: "Scores of the people who were the most enthusiastic advocates of the earth road as sufficient for Iowa's needs have lost patience and have come to the conclusion that it is a waste of energy to continue further on such a policy. Most of the county systems have reached a stage where the dirt surface has every advantage of good grade, good surface and good underdrainage. There has also been the advantage of fairly persistent dragging. If earth roads are ever going to be entirely satisfactory for heavily traveled roads, they have been given every chance in Iowa the last few years. With the grades built and drainage taken care of, the next logical step, if the dirt surface fails, is to put down a strip of hard surfacing." This is sound doctrine.

Railway Bridge Impact Allowances

TAKING proper account of the effect of moving trains on bridges—a crucial problem since the earliest days of the iron bridge—will reach a new stage of progress if the American Railway Engineering Association adopts the impact formula which it has had as a tentative standard for several years. The formula invites confidence, since it is based on tests to determine the stress increase caused by the motion of a train. Unfortunately, bridge men of wide experience raise certain objections to its practical value, and this latter, of course, is the real touchstone.

As compared with the earlier standard, the widely used empirical formula $I = 300/(L + 300)$ of the late C. C. Schneider, the new one will give higher impact values for short spans and very much lower values for long spans. Both effects are of questionable value.

Not only does the new formula demand higher impact allowance for short spans when L, the length, is taken at the same figure, but it adds to this effect in the case of main girders of bridges carrying two or more tracks. The old formula took L as the loaded length which produces maximum stress, and thus automatically reduced the impact tax on a multitrack bridge. The new formula, taking L as the span length, imposes severer requirements, which are only partly relieved by the provision of live-load reduction factors for multi-track bridges. It results herefrom that more metal will have to be used in bridges shorter than 100-ft. span.

But these, in modern practice, are plate-girder spans. Floor systems, which are also affected, are likewise of plate-girder construction. No type of bridge, it is safe to say, has given better account of itself, in many years of experience, than the plate-girder span. If this type is now to be penalized by a higher impact addition, is the procedure to be regarded as logical or in the interests of economy? It is true that floor systems have often shown weakness, but this was due to increased engine weights and not to impact. The fact remains that plate-girders, our most robust steel members, do not need the further increase of metal which the new formula will require.

Applied to long spans, on the other hand, the new

formula gives remarkably low figures, 5 to 15% impact in place of the 25 to 40% which the old formula yielded. At first sight this is an improvement, for no one believes that 30% impact really occurs in the main members of a 700-ft. span; the 6% which the new formula demands is more logical. However, true impact is not the only action that an impact formula must cover.

Whether we wish it or not, we actually provide by the impact formula for all live-load effects, of whatever nature, even though they may not be measurable as axial stress increments. The formula, further, must serve as a blanket allowance to cover the secondary stresses. For a long time to come, secondary stresses will be computed only for extraordinary spans, and even here the reliability of the calculations is doubtful.

Briefly stated, the fact is that under the methods of today the impact formula constitutes the only discrimination between the effects of a moving train on a real bridge and the effects of dead weight on an ideal bridge. Do these effects differ by only 5 or 6%? Unless this allowance does actually cover all live-load effects and their secondary stresses—always more severe than dead-load secondaries—the new formula will have the rather curious result of permitting a higher working-stress for live load than for dead load. In this aspect the operation of the old formula is manifestly fairer.

We have quoted these practical considerations rather fully because the matter of impact increments touches very closely some of the problems at the core of bridge design. The subject is complex; but its practical aspect is more simple, and this, we believe, is controlling.

The objections offered from the standpoint of practice do not question the theoretical excellence of the formula or the merits of the investigations on which it rests. They are concerned solely with the service value of the formula and with its influence on the efficiency of bridge design, and they claim attention accordingly.

Need for a National Technical Highway Association

LAST week the American Road Builders' Association drew to its convention a representative and interested group of highway engineers and builders from the Eastern states. Ohio was represented, as well as the Southern states, but, on the whole, the description of the gathering as an Eastern meeting is correct. The association is now the only one in the highway field which devotes itself to technical matters and professes a desire to be national in scope. There is need for such a national body, but whether the American Road Builders will be that association is doubtful.

In the first place, it is on a false basis so far as technical strength goes; it admits material and machinery manufacturers and salesmen on the same basis as engineers and contractors. Second, the Eastern dominance that has restricted the organization in the past is as strong as ever, and is not likely to be abated. The geographical representation in the directorate is wide, but it is scenic rather than active.

It may be seriously questioned whether an organization with headquarters in New York can become the national association of road builders. The gravitation toward New York, natural in some industries and professions, does not obtain in the case of highways. New York may be more important to the banker, the manufacturer, the importer, the engineer, than any other city in the country but the logical headquarters for a national road-builders' association is near the population center. Doubtless similar reasoning located the Associated General Contractors of America in Chicago.

But even if there is no immediate effort to establish a national association in Chicago we do not expect the American Road Builders' Association to be anything but an Eastern organization—unless there should come a sharp break with its traditions and management.

All of which points to the need for a strong technical highway association of national scope, and does not detract from the fact that last week's convention was a good one and that as an Eastern organization the American Road Builders' Association can be of much value to road builders and the road-building art.

How Much Education For Minor Engineering Positions?

MR. GOODELL'S letter on p. 482 of this issue sounds a new note in the current discussion of engineering compensation. His thought, in brief, is this: Men should not be educated beyond the jobs they are likely to hold. Conversely, every man who goes through a technical school feels he has a guarantee that he will be given a prominent position at free-from-worry compensation. Consequently, if the busy world refuses to make good the guarantee the individual feels that he has been victimized. For remedy, Mr. Goodell proposes that for the minor positions in engineering—such as surveying, inspection and the simpler jobs in designing—there be high-school (or trade-school) courses.

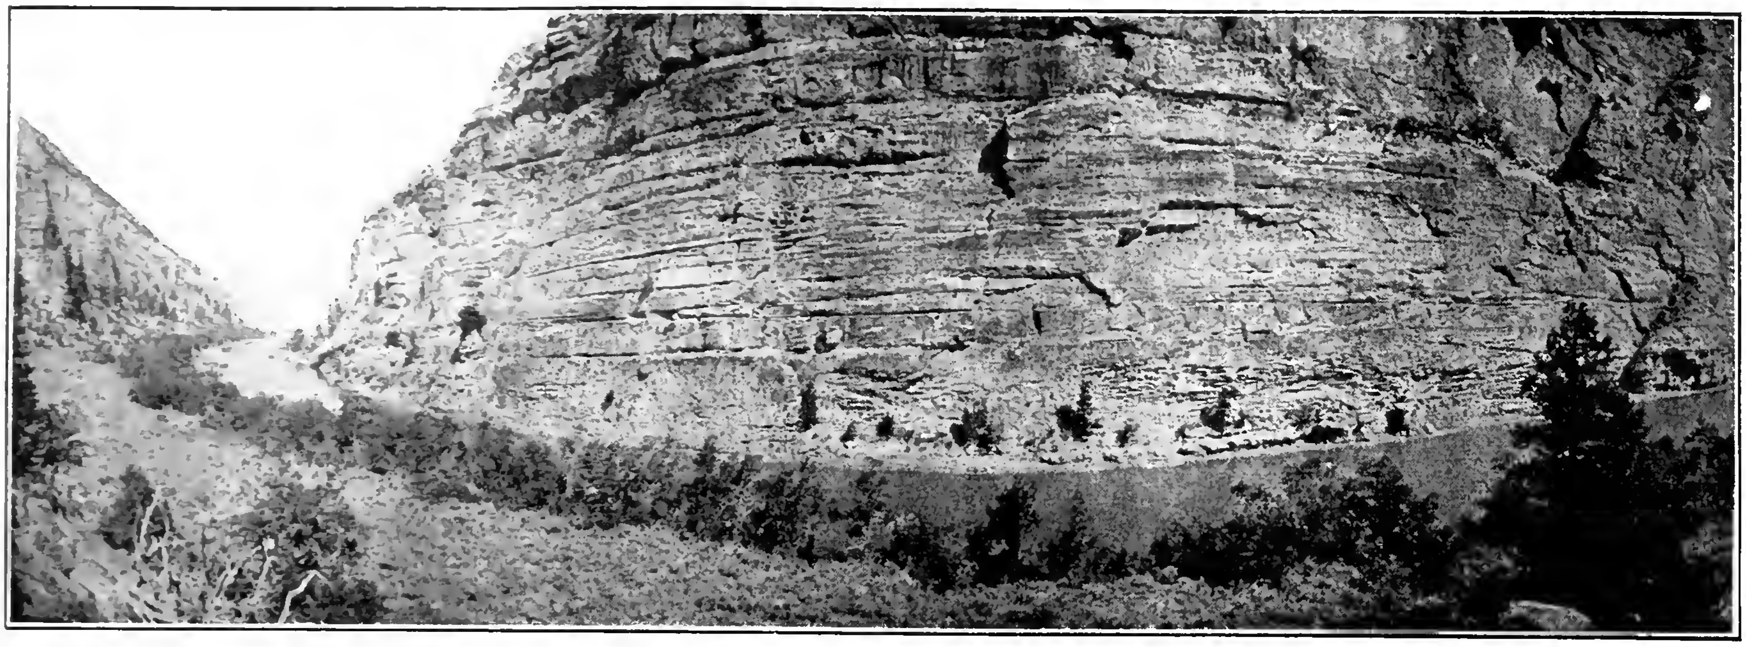
Here surely is much food for thought. The suggestion fits in with the theory of the technician courses given by the Army during the war to prepare airplane mechanics, concrete workers, etc. Moreover, its purpose is similar to that of the plan for two-year courses in engineering in technical schools. Such courses would be elected by those unable, for financial or other reasons, to stay for four years, or whose ability fitted in better with quite narrow specialization than with the broader work for which a four-year course is a preparation.

To Mr. Goodell's plan less objection will probably be made than to the two-year college courses here suggested, for many who see the wood-hewing and water-drawing character of numberless minor positions on engineering work will protest vigorously against any plan that might seem to lower engineering standards. In our judgment, however, engineering standards are lowered more by having within the profession a lot of discontented men than by instituting short, highly specialized courses. Both plans are in the interest of human conservation. Neither controverts the ideas of the Mann report. In fact, by the method of testing Dr. Mann proposes it may eventually be possible to determine which men had better stop at the high school and which might with profit spend two years in college. Mr. Goodell's plan, to be workable, requires that engineers recognize the correctness of his analysis and endeavor to divert from college those who had best stop their work on completing the high-school course.

Colorado River Flood Control by Storage

Reservoirs at Available Sites Would So Cut the Flood at Yuma as to Safeguard the Imperial Valley—Water-Power and Irrigation Opportunities—A Hundred More Gaging Stations Needed

By E. C. La Rue
Hydraulic Engineer, United States Geological Survey, Pasadena, Cal.



HORSESHOE CANYON OF THE GREEN RIVER IN UTAH, SHOWING FLAMING GORGE DAM SITE AT THE LEFT
A dam here with a spillway 255 ft. above low water would form a reservoir extending well up into Wyoming with a capacity of 4,720,000 acre-feet.

STORAGE on the Colorado River would control the floods which threaten the Imperial Valley. Great power and irrigation possibilities might also be developed by dam building and storage. In a broad political sense, the problem is a large and complicated one, because it involves not only seven large states but also the Republic of Mexico. This article will be devoted chiefly to flood control by storage, but some consideration will also be given to the other aspects of this great stream.

The Colorado is formed by the junction of the Green and Grand Rivers in southeastern Utah. It flows in a southwesterly direction across northwestern Arizona, and forms the boundary between Arizona and the States of Nevada and California. The Green, which rises in the Wind River Mountains in Wyoming, drains an area of 44,400 square miles. The Grand rises on the western slope of the continental divide in central Colorado, and drains an area of 25,900 square miles. Including the Green, the entire length of the Colorado River is 1700 miles. The total fall from source to mouth is more than 14,000 ft. The drainage basin of the Colorado (244,000 square miles) comprises the southwestern part of Wyoming, the eastern half of Utah, the western part of Colorado, practically all of Arizona, and small portions of California, Nevada, New Mexico and Old Mexico. Most of this area is arid. The streams receive their main supply from the melting snow from the high mountains of Wyoming, Utah and Colorado.

Irrigation and Water-Power—Some of the largest irrigation, storage and water-power projects in the Western United States are in the Colorado River basin. When these projects are completed, probably more than $100,000,000 will have been expended. Considering the basin as a whole, the area irrigated in 1913 was about 1,600,000 acres. By proper regulation and control of the water-supply the irrigated area in the basin may be increased to about 7,000,000 acres.

The present developed water power in the Colorado River basin is about 76,000 hp. The total undeveloped water power may exceed 3,000,000 horsepower.

Flood Control—That the floods of the lower Colorado should be controlled was shown by the writer in his report, "Colorado River and Its Utilization," published by the United States Geological Survey as Water-Supply Paper 395.

The elevation of the water surface of the Colorado River at Bulls Head Rock (see map) is 500 ft. above sea level. The distance by river between Bulls Head Rock and the Gulf of California is 370 miles; the average fall in this section of the river, therefore, is 1.35 ft. per mile. Between Bulls Head and Yuma, Ariz., about 200,000 acres of irrigable land are subject to overflow during periods of high run-off. From Yuma to the Gulf the river flows through its delta, which is made up of silt brought down and deposited during past centuries. At low stages the river winds through the delta in a channel fairly well defined by banks 10 to 12 ft. in average height; at high stages it overflows its banks at many points. After the river has flowed in one channel for a number of years, its bed and banks are built up by silt deposits, until the stream itself occupies a ridge on the delta. As the slope of the delta is greatest toward the north and west, the river during flood periods is continually seeking a new channel to Salton Sea. Several million dollars have been expended by private interests and the Federal Government in constructing more or less temporary levees and protective works to prevent overflow of the Colorado into Salton Basin. The value of the property in Imperial Valley subject to injury by overflow has been

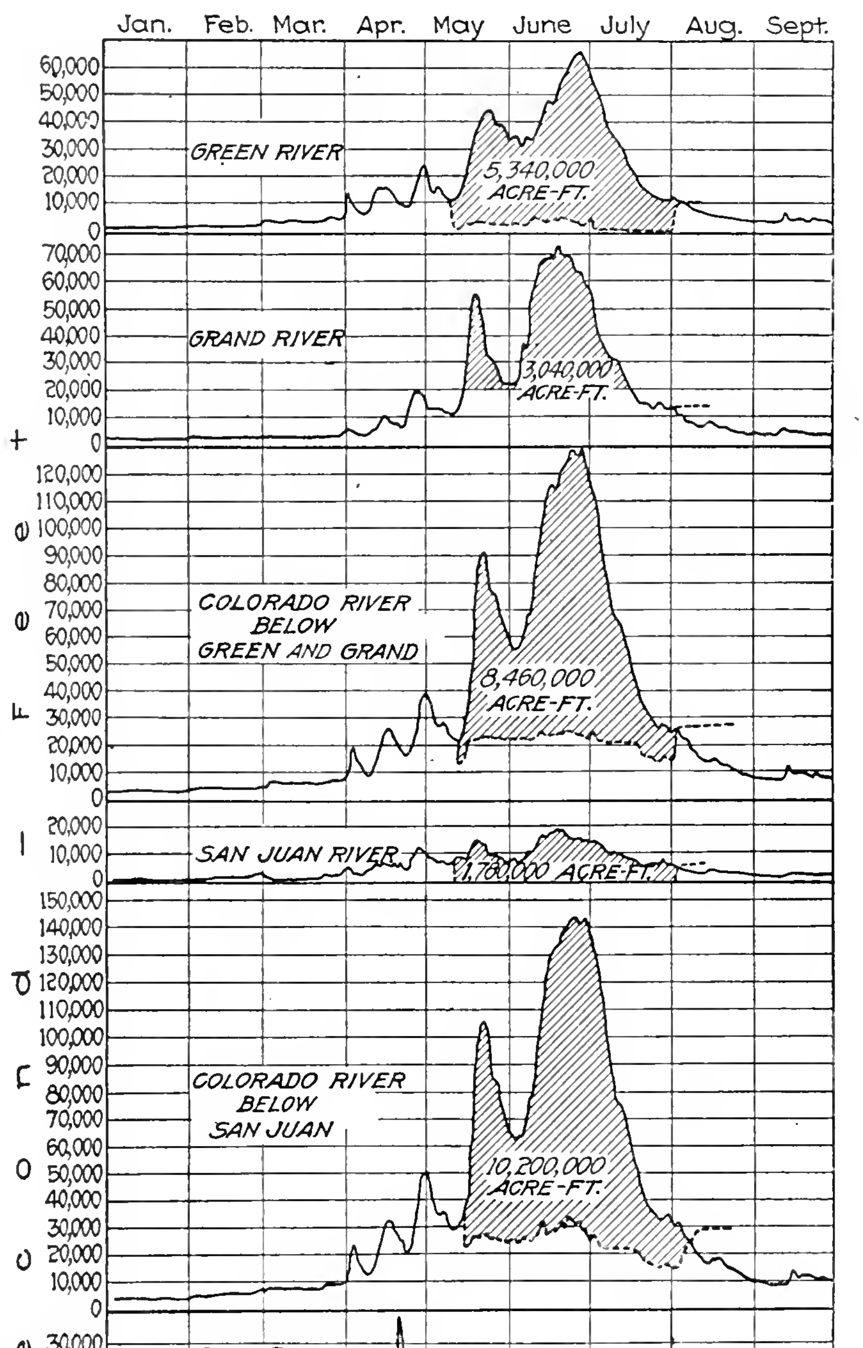
PROPOSED FLOOD-CONTROL RESERVOIR SITES IN THE COLORADO RIVER BASIN

variously estimated at $30,000,000 to $50,000,000. Between Bulls Head Rock and the international boundary are properties valued at $10,000,000 to $15,000,000, which also need protection from the floods of the Colorado.

Obviously, no amount of levee construction and bank revetment will prevent high-water stages on the lower Colorado, and if floods are not prevented thousands of dollars must be expended annually in maintaining protective works on the river below Bulls Head Rock. For the control of the extremely high stages only one method is available—the construction of properly located storage reservoirs of sufficient capacity to hold back the flood-making waters. If by this means all or the greater part of the overflow is prevented, the lands along the lower river can be adequately protected by bank revetment, and the cost of maintaining protective works will have been reduced to a minimum.

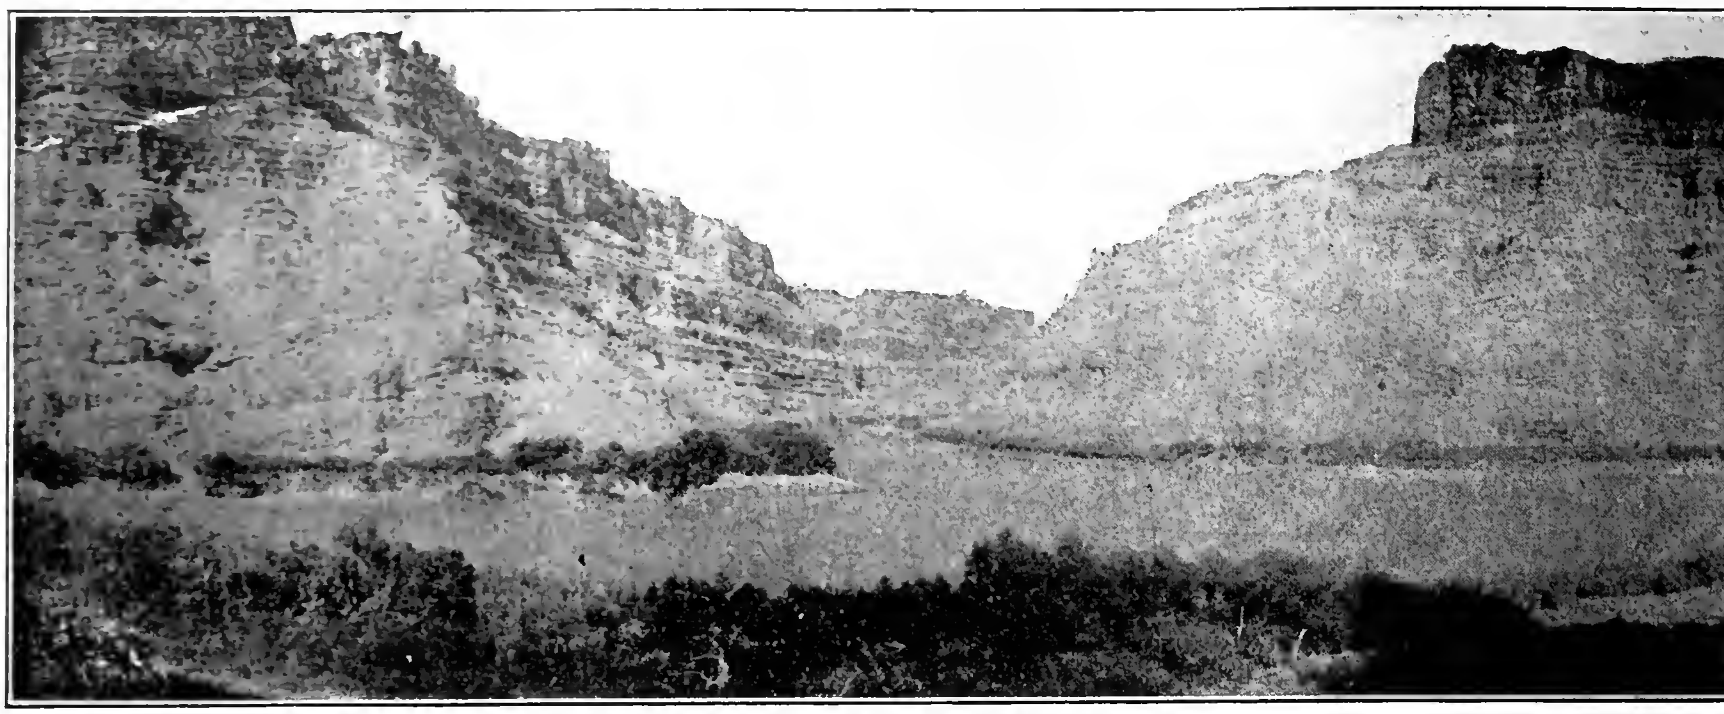
Prominent engineers have expressed the opinion that the influence of reservoirs on flood prevention rapidly diminishes down stream, and the influence of levees correspondingly increases in importance as a method of flood protection, and that for the lower alluvial reaches of long rivers, such as the Mississippi and Colorado, levees afford the only sure means of flood control.

The foregoing statement is not correct when applied to the Colorado River. Although the Colorado, including the Green, is 1700 miles long, and drains an area of 244,000 square miles, the precipitation and run-off from the lower half of the basin is small compared with that from the upper half. At Yuma, Ariz., 92% of the annual run-off is contributed by that part of the drainage basin above the Utah-Arizona line, which is 700 miles above Yuma. The Green and the Grand Rivers, which unite to form the Colorado, drain 70,300 square miles, which is only 28% of the Colorado River basin;



DAILY FLOW OF THE GREEN, GRAND, SAN JUAN, GILA AND COLORADO RIVERS FROM JAN. 1 TO SEPT. 30, 1917

The irregular curve represents the daily flow at each river station. During February the flow at Yuma was less than 10,000 sec.-ft., except during the last two days; during the first four days in July the flow was more than 140,000 sec.-ft. The shaded area on the chart shows the part of the flood that might have been stored in reservoirs. The dotted line below the shaded area indicates the flow resulting from such storage. The chart shows that at Yuma the flood flow could have been reduced from 143,000 to 33,000 second-feet.



JUNCTION OF THE GREEN AND GRAND RIVERS IN UTAH AT OR NEAR PROPOSED DAM SITE

A reservoir with a capacity of 8,600,000 acre-ft., extending for many miles up both rivers, could be formed by a dam with a spillway 270 ft. above low water. Such a reservoir, with a 2,000,000-acre-ft. reservoir on the San Juan River, would have reduced to 25,000 sec.-ft. the flood flow of the Colorado at Yuma in 1917.

yet these rivers contribute 76% of the water that passes Yuma. The junction of the Green and Grand Rivers is 1000 miles above the Gulf of California.

As a result of investigations made by engineers employed by the Federal Government, sufficient data are available to show that there are reservoir sites properly located and with sufficient capacity to hold back the flood-making waters. Some of the more important reservoir sites are shown on the accompanying map. The capacities of these sites, all of which can be utilized, are given in the following table:

Name of Site	Elevation of Spillway Above Low Water, Ft.	Capacity, Acre-Feet
Flaming Gorge	200	2,600,000
Flaming Gorge	255	4,720,000
Juniper Mountain	200	1,600,000
Ouray	170	8,000,000
Ouray	190	10,000,000
Ouray	220	15,000,000
Green-Grand	180	3,330,000
Green-Grand	200	4,250,000
Green-Grand	240	6,460,000
Green-Grand	270	8,600,000
Kremmling	100	574,000
Kremmling	150	1,240,000
Kremmling	200	2,200,000
Bluff	214	1,600,000
Bluff	264	2,600,000

The utilization of the Colorado River presents a complicated problem: The extreme floods must be prevented, water must be stored for irrigation, and at many points it may be desirable to regulate the flow for power development. The value of each site and the capacity to which it should be utilized will be determined by a study of the problem as a whole. Each large undertaking should be but a unit of the great project which, when completed, will result in the utilization of the entire water resources of the Colorado River basin.

The Colorado River Flood of 1917—During the winter of 1916-17 the snowfall in the upper basin of the Colorado River was unusually heavy. The spring of 1917 was cool. On May 10 the upper tributaries began to rise, and the automatic water-stage recorders maintained by the United States Geological Survay gave warning that the flood period was near. Fourteen days later the flow of Green River increased to 42,400 sec.-ft., and reached its maximum discharge of 65,900 sec.-ft. on June 27. The maximum flood flow of the Grand River —73,200 sec.ft.—occurred June 19-21. On June 28 the peak flood of 129,000 sec.-ft. occurred immediately below the junction of the Green and Grand Rivers. The San Juan River contributed 18,700 sec.-ft. on June 17, and with the unrecorded flow of the Frémont and Escalante Rivers, the maximum flow of the Colorado River at the Utah-Arizona boundary reached about 147,000 sec.-ft. June 25. The maximum discharge for the year at Yuma, 143,000 sec.-ft., was recorded July 4. This was one of the greatest summer floods ever recorded on the lower Colorado. The levees were overtopped in the vicinity of Needles and near Volcano Lake, in Mexico.

It will be interesting to analyze the stream-flow records and determine to what extent the flood of 1917 could have been prevented by means of storage. A chart has been prepared on which the daily discharge of the Colorado and its principal tributaries is shown for the period of Jan. 1 to Sept. 30, 1917.

The flow of Green River was obtained by adding the flow of San Rafael River to the recorded flow of Green River at Little Valley, Utah. These stations are about 90 miles above the mouth of the Green. The gaging station on Grand River is near Cisco, Utah, about 90 miles above the junction of the Green and Grand Rivers. No tributaries of appreciable size join the Grand River below the gaging station near Cisco. During the flood stage it requires about 24 hours for the water to flow to the junction of the Green and Grand Rivers from the gaging stations above mentioned. The combined flow of the Green River at Little Valley, the San Rafael near its mouth, and the Grand at Cisco, represents with fair accuracy the flow of the Colorado immediately below the junction of the Green and Grand Rivers. By adding the flow of the San Juan River, the discharge of the Colorado below the mouth of the San Juan is obtained. This latter record, as shown on the chart, is approximately correct, except that the flow of the Frémont and Escalante Rivers has not been added. No record was kept of the flow of these streams, but it is

unlikely that they increased by more than 3000 sec.-ft. the maximum flood of the Colorado. The daily discharge of the Gila River was placed on the chart to show that this tributary was dry while the Colorado was in flood from June 5 to Aug. 1.

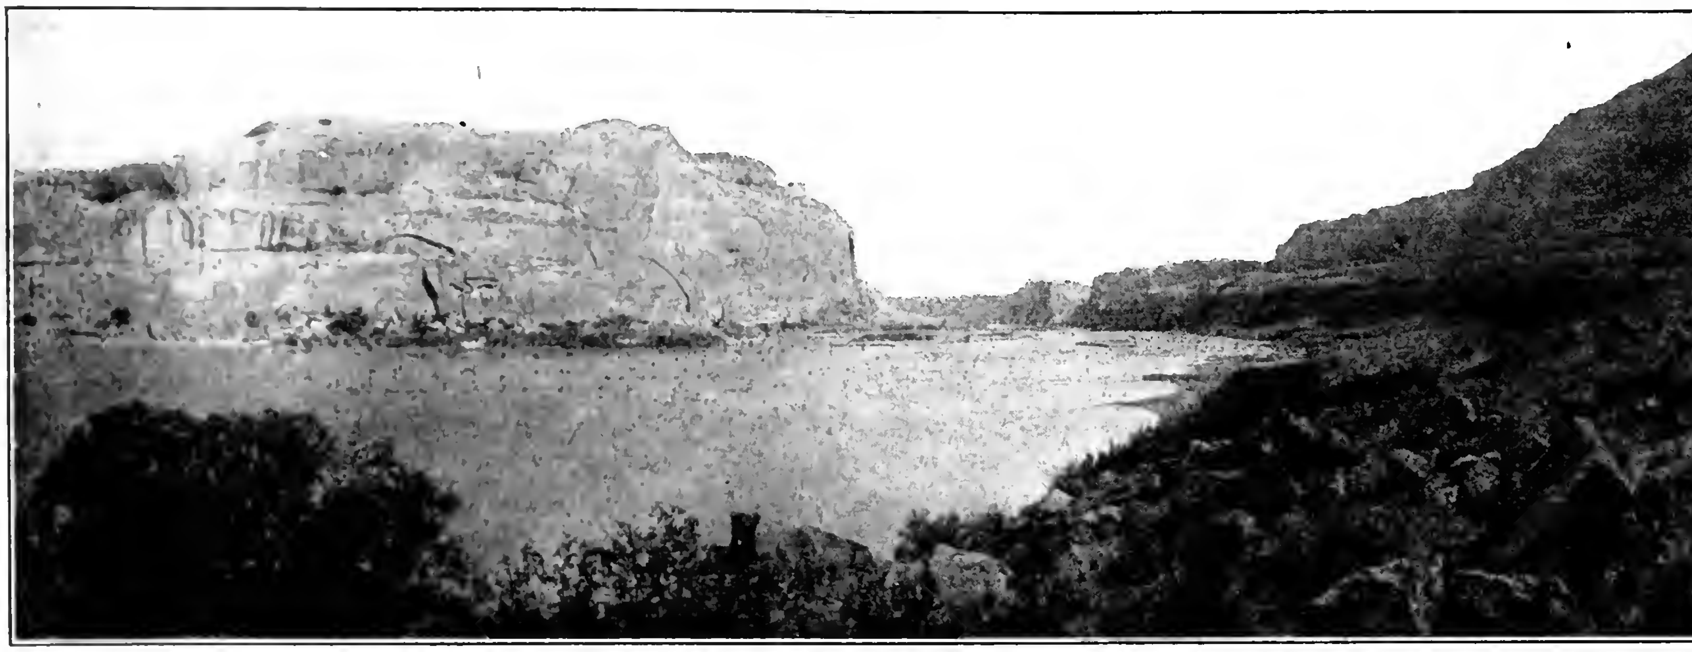
There is a reservoir site on the Green River at Ouray, Utah, where a capacity of 10,000,000 acre-ft. may be obtained by raising the water level 190 ft. The capacity of this site is much greater than that required to control completely the flow of Green River below the mouth of the Duchesne and White Rivers. Had this reservoir been in operation in 1917, the portion of the flow of Green River shown by the shaded part of the chart could have been stored. The peak flood of Green River at its mouth would have been reduced from 65,900 to 5200 second-feet.

Only preliminary data are available relating to the possibilities of storage on the lower Grand River. It is believed that there is a feasible dam site on Grand River a few miles above its mouth, where a capacity of 3,000,000 acre-ft. may be obtained, and there is another storage basin on Grand River near the mouth of the Dolores. The Kremmling site, near the headwaters of the Grand, affords storage capacity of 2,200,000 acre-ft. for a dam 230 ft. in height.

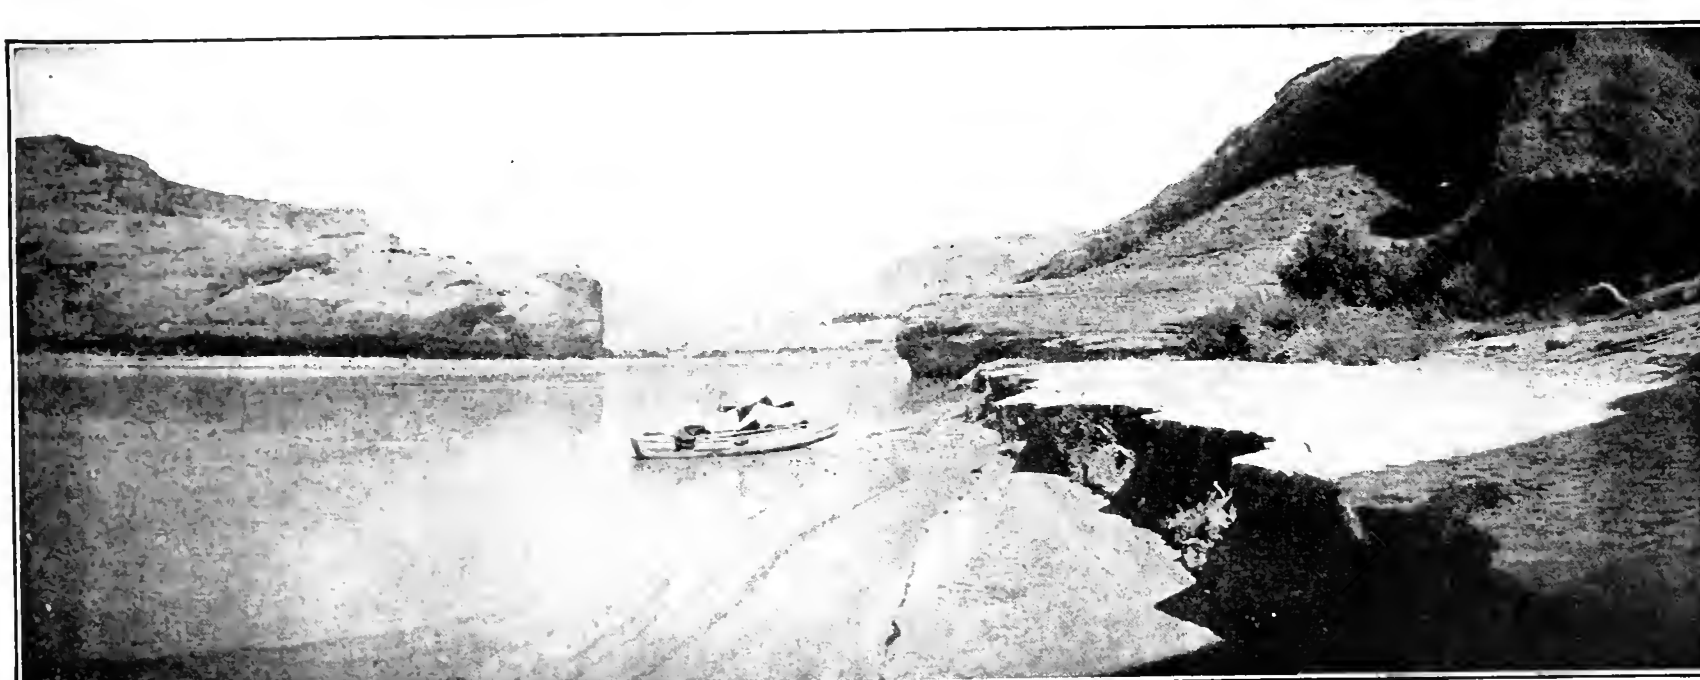
The writer has taken a pessimistic view of the possibilities of storage on the lower Grand, and has assumed that it would be necessary to allow 20,000 sec.-ft. to pass so that the capacity of the reservoirs would not be overtaxed. Under this assumption, the flood flow of the Grand River could have been reduced from 73,200 to 20,000 sec.-ft. by the storage of 3,040,000 acre-feet.

On the San Juan River, near Bluff, Utah, a dam 264 ft. high would give a storage capacity of 2,600,000 acre-ft. As shown by the chart, the entire flow of San Juan River could have been cut off during the flood period, and the amount of water stored would have been 1,780,000 acre-ft., or 920,000 acre-ft. less than the capacity of the reservoir. The San Juan is silt laden, and it may be necessary to build retarding basins on this stream.

Referring again to the chart, the shaded portion shows that part of the flood flow at Yuma which could



BEDROCK REACHES THE SURFACE FROM SHORE TO SHORE AT NO OTHER KNOWN POINT ABOVE THE GRAND CANYON
This point is 21 miles above the Escalante River and 100 miles below the junction of the Green and Grand Rivers



THERE IS A HEAVY SILT DEPOSIT 12 MILES BELOW THE MOUTH OF THE SAN JUAN RIVER
This and the other pictures shown were taken by the author while making a boat trip through the cañons of the Green and Colorado Rivers in 1915.

have been held in storage reservoirs in the upper basin. The unshaded area below the dotted line shows the regulated flow. The maximum flood at Yuma could have been reduced from 143,000 to 33,000 second-feet.

By the building of a dam below the junction of the Green and Grand Rivers that would raise the water level 270 ft., a reservoir having a storage capacity of 8,600,000 acre-ft. could be created. By the utilizing of this site to its full capacity, and the Bluff reservoir site on San Juan River to a capacity of 2,000,000 acre-ft., the flow of the Colorado at Yuma during the flood period of 1917 could have been reduced to less than 25,000 sec.-ft. It is thus seen that by the utilizing of two reservoir sites the floods of the lower Colorado may be prevented. The site at the junction of the Green and Grand Rivers is known as the Green-Grand reservoir site and is described in Water-Supply Paper 395, issued by the United States Geological Survey.

About 100 miles below the junction of the Green and Grand Rivers there is a section where solid rock extends across the channel of the Colorado River. This is the only point on the Colorado above the Grand Cañon where bedrock is known to extend across the channel at the surface. This dam site may prove valuable at some future time in connection with the development of storage and water power. Instrumental surveys have never been made on this section of Colorado River. The amount of silt carried by the Colorado at this point is comparatively small. San Juan River contributes the greater part of silt found in the Colorado above Grand Cañon.

The above data are submitted as proof that by utilizing two reservoir sites, or a combination of three or four sites, the summer flood on the lower Colorado in 1917 could have been prevented.

The sudden floods from the Gila River will always be a menace to the water users below Yuma unless these floods are controlled by storage in the Gila basin.

With the flow of the Colorado placed under control by storage, the cost of maintaining the levees will be reduced to a minimum and an adequate supply of water for irrigation will be available for all time. Some water power may be developed at the storage dams, and new lands may be placed under irrigation in the upper basin. As a result of storage, the water-supply would be sufficient at all times to meet the demand for the irrigation of more than 2,000,000 acres of new lands on the lower river.

Emergency Storage Dam at Bulls Head Rock—During the summer of 1906 the Colorado River changed its course and flowed north into Salton Basin. The break was not closed until February, 1907. The cost incidental to closing the break and the damage to property in the Imperial Valley amounted to several million dollars. With the exception of construction of levees and works protecting the banks, nothing has been done to prevent the recurrence of this catastrophe. A sudden summer flood from the upper Colorado may overtop the levees at any time. With their lands and homes below sea level and the Colorado flowing on a ridge in the delta above them, the people in the Imperial Valley cannot feel secure until every precaution has been taken to prevent overflow and to keep the river in the channel leading to the Gulf of California.

It was the floods from the Gila River that overtopped the levees and caused the break in 1905. These floods are of short duration, rarely lasting more than a few days, yet the break was not closed in time to prevent the summer flood water from the upper Colorado from flowing north into Salton Basin. If it had been possible to shut off the flow of the Colorado for a period of two weeks, the break could doubtless have been closed if a railroad trestle had been constructed across the crevasse and cars loaded with rock had been in readiness. The writer believes that by the utilization of an emergency storage dam at Bulls Head Rock the river below the Imperial Canal heading can be made dry at any time for a period of three weeks when the stage of the river is 10,000 sec.-ft. or less. With such a dam in operation the Colorado might flow north into Salton Basin for a short period but not for two years.

A dam could be constructed at Bulls Head, designed primarily for the diversion of the river at the 20-ft. level for the irrigation of about 56,000 acres, but carried high enough to store water to the 60-ft. level. The storage capacity between the 20-ft. and 60-ft.

COLORADO RIVER CANYON EIGHT MILES ABOVE LEE FERRY, ARIZ., WHERE WALLS ARE ALMOST 1500 FEET HIGH

levels is 243,000 acre-ft. If a break in the levee should occur below the heading of the Imperial Canal during the summer floods, preparation for closing it could be made while the river was still flowing into Salton Sea, and when the discharge had fallen to 10,000 sec.-ft. the spillway and canal head gates at Bulls Head could be closed. The Palo Verde, Imperial and Yuma canals could take care of 5000 sec.-ft., and the remaining 5000 sec.-ft. could be stored for 24 days, during which time the river channel at the break would be dry and the break could no doubt be effectively repaired. The capacity of the reservoir above the 20-ft. level would not be impaired by the deposition of silt, for it would be used as a storage reservoir only in an emergency and for a short period.

A Complicated Problem—The Colorado is not only an interstate but an international stream. The Federal Government, in coöperation with the seven states affected, should formulate plans for the collection of engineering, stream-flow, and water-right data in order that the meager information now available may be increased as rapidly as possible. The interests of each state affected should be taken care of, and there should be a thorough understanding between the United States and the Republic of Mexico regarding the use of the waters of the lower Colorado.

The most neglected part of the investigations of the Colorado River is the collection of stream-flow data. A knowledge of the flow of the main stream and all its tributaries is of primary importance. The amount of water available for the various irrigation, storage and water-power projects must be known before the value of these respective projects can be determined. Especially does this apply to the large storage reservoir sites in the upper basin. The relative value of these sites will depend largely on the volume of the floods and the annual run-off available for storage.

Time is required to collect dependable stream-flow data. The longer the record the more valuable. A hundred or more new gaging stations should be established and a fund of at least $50,000 should be available annually for carrying on this work.

Wider Pavements Needed by Motor Vehicles at Curves

Theoretical Width Determined by Formula—Chart of Necessary and Recommended Widths Plotted for Various Radii

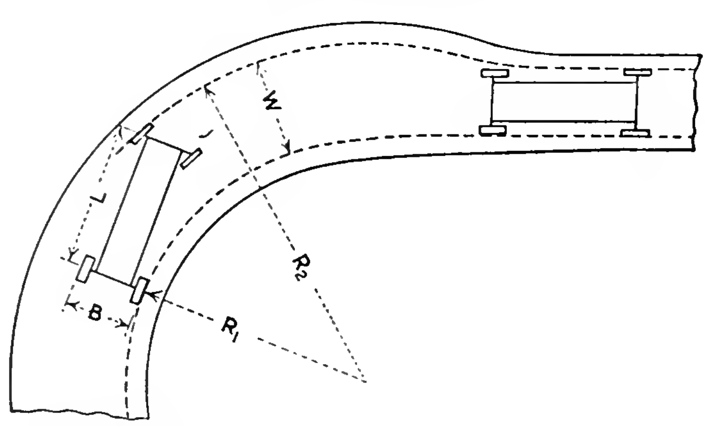
By G. S. Eaton

Assistant Division Engineer, Promotion Bureau, Universal Portland Cement Company

EXTRA width required by modern motor trucks when rounding curves should receive careful consideration when narrow pavements for country roads and driveways around industrial plants are designed. Too narrow a roadway means traffic inefficiency; too wide a pavement requires unnecessary expenditure. The adoption, for general hauling, of large trucks, which have a longer wheel base and greater width than horse-drawn vehicles, and a peculiar action in turning due to the fixed front axle, has changed traffic conditions. Even on the wider city streets, especially at intersections, attention must be given to these developments.

The action of a truck in rounding a sharp curve will be made clear by reference to the illustration which shows a truck turning on a one-lane pavement. Assuming that the machine is turning at constant radius, the width of the pavement theoretically required can be obtained by the formulas $R_2 = \sqrt{(R_1 + B)^2 + L^2}$ and $W = R_2 - R_1$, where W is the width of pavement; R_2, the radius of the outside of the outer front wheel; R_1, the radius of the inside of the inner back wheel; B, the out-to-out of rear wheels; and L, the length of wheel base. For example, a truck 7 ft. wide with 15 ft. wheel base requires a roadway more than 10 ft. wide when turning on a radius of 25 ft., in order that it may keep on the pavement. While there are minor inaccuracies in the above formula, such as difference in width at the front and the rear trucks and variations caused by the knuckle joints on the front truck, the error is unimportant, as a safety factor is desirable in any event.

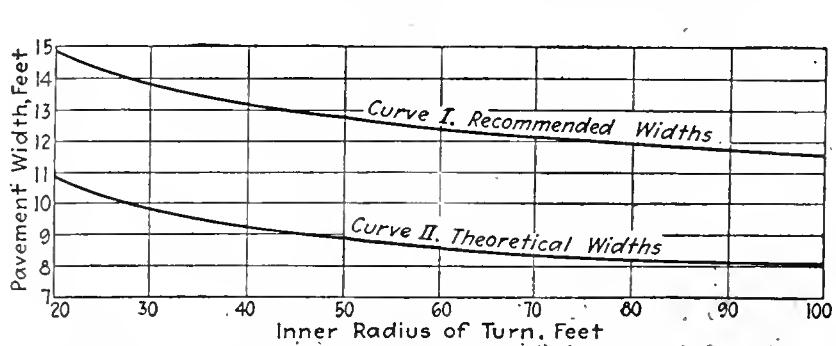
Passenger automobiles also require considerable extra width, as is shown by actual measurements made of the turning radius of an automobile of 137-in. wheel base and 56-in. tread. When the inside rear wheel was turning on a radius of 13.9 ft.—a minimum for this car—the radius of the outer front wheel was found to be 22 ft. Substituting in the formula, $R_2 = 21.8$ ft.,



ACTION OF MOTOR TRUCK IN ROUNDING A CURVE, AND SUGGESTED WIDENING

checking the field measurements almost exactly. The width needed in this case was 8.1 ft., or 72% more than the tread.

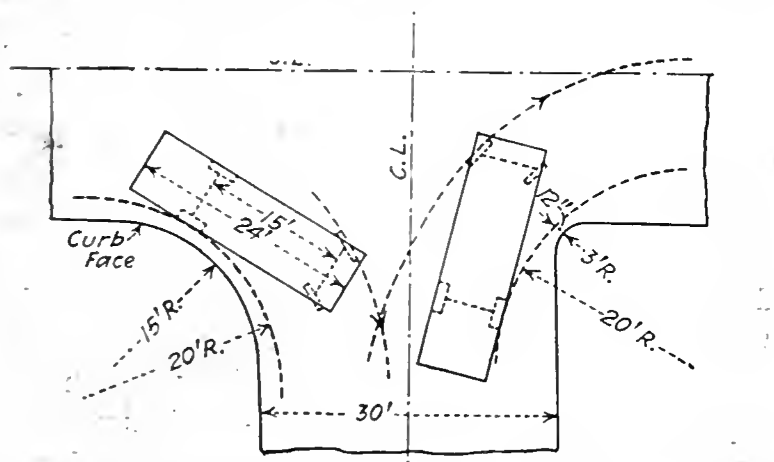
The width theoretically required for a truck with a 15-ft. wheel base and a 7-ft. width, when turning with any inside radius between 20 and 100 ft., can be obtained from curve I. Curve II shows width suggested for actual use, and is based on widening amounts which vary from 4 ft. more than the theoretical require-



THEORETICAL AND RECOMMENDED WIDTHS OF LANE FOR VARIOUS RADII SHOWN GRAPHICALLY

ments for a curve of 20-ft. inside radius, to 3 ft. on a tangent. This gives a pavement 10 ft. wide on straight sections. Where pedestrian traffic uses the road 11 or 12 ft. is preferable, with corresponding increases at turns. The recommended widths are desirable though not absolutely necessary, as they save the time and cost of slowing down for safety. The minimum inside turning radius of the average large truck is slightly less than 20 ft.; with some trucks a larger radius is necessary, and in all cases it is desirable. From curve I it may be seen that the extra width is needed even on curves of considerable radius, 48 ft. requiring about two feet.

Where provision must be made for two trucks to pass on a curve, the total length of the truck attains importance, particularly when there is any overhang



BEHAVIOR OF TRUCKS PASSING AT INTERSECTIONS

beyond the front axle. Although the overhang back of the rear axle is not important when both machines are following arcs of concentric circles, sufficient width should be provided to leave clearance when the arcs are not concentric.

Widths for double-track pavements may be obtained from curves I and II by doubling the values shown for the single track. While this is not exact, the error is small for turning radii of practical importance, and is on the side of safety. The shape of the truck assumes importance where vehicles are expected to pass on the curve, especially the distance from the rear axle to the front of the truck, if the body is of the same breadth throughout. Doubling the values, however, will allow sufficient clearance with the usual truck. That the extra width is needed for some distance past the point of curve is evident from the illustrations. This means that both three-way and four-way intersections on narrow pavements should be widened for some distance beyond the usual points of curvature, where short radii turns are constructed.

Space occupied by motor vehicles in turning is of considerable importance in street construction as well as on the narrower pavements. The more expensive types of pavement are being generally constructed, and the matter of deciding on the most economical width, where the excess adds materially to the cost, is more important than heretofore.

Street pavements wide enough on straight sections may prove too narrow at intersections, unless care is taken to construct curbs of large radii. For example, with the old-style curb, rounded on a radius of 3 or 4 ft., a modern truck of 15-ft. wheel base and 7-ft. width cannot make a right-angle turn from one 30-ft. pavement to another and still remain on its own side of the center line of the street. Should two trucks going in opposite directions, as shown in one of the illustrations, attempt to turn at the same time, with a turning radius of 20 ft. for the inner rear wheel, a collision would be likely to result. But where the curb radius is as great as 15 ft., the two could make the turn safely, with several feet to spare.

With a continuously increasing percentage of motor traffic, driven at much greater speeds than formerly, and with widths of tread up to 7½ ft., the customary 8-ft. lane is too narrow, and a greater margin of safety should be allowed. In all highway improvements of a permanent nature allowance should be made for still further increases in the sizes of motor trucks, as well as for great development in their use.

Licensing Bill Proposed by American Association Committee

THE Committee on Legislation of the American Association of Engineers, L. K. Sherman, chairman, has just prepared a form of licensing bill which is designed to include all classes of engineers, although certificates in each branch are prescribed. In all essential details it is the same as that of the Joint Committee written in 1915 (see *Engineering News-Record* of Feb. 27, 1919, p. 423), but is unique in the fact that it includes land surveyors by name and definition. The following general features are given for comparison with the Joint Committee bill:

A "surveyor" is defined as any person engaged in locating, establishing, or relocating any land boundary lines between two or more land owners, or locating any United States Government, state, county, township, or municipal land survey lines, or the lines of any public streets or roads.

The state board would consist of five members instead of nine—three civil engineers, one mining or electrical engineer, and one mechanical engineer or naval architect, and one professor of engineering in the state university. The regular terms would be four years, instead of six, and the qualifications are the same, except that a three-year residence in the state is required instead of one. Compensation would be paid at the rate of $10 per day, instead of no compensation, as in the Joint Committee's bill. The officers are elected annually instead of biennially and are called chairman, vice-chairman, and secretary, the secretary being a member of the board and being required to furnish a $3000 surety bond. At all meetings a majority shall constitute a quorum; the reports shall be made annually on or before June 30, instead of Feb. 1.

For admission to examination, a $15 fee is required, practice in land surveying is accepted, and as the alternative to six years' practice only two years' practice instead of four is specified in addition to graduation from an engineering school, and the following is added as a part of the graduation requirement of the candidate, "That he is qualified in the knowledge and prac-

tical application of the principles of physics, strength of materials, and mathematics, including trigonometry."

Examinations are held to determine the qualifications *separately in surveying or in any one of the branches of professional engineering.* An additional fee of $10 is required for certificates of registration. *These certificates are issued in the branch or branches of engineering in which the candidate is qualified, or in land surveying,* and authorize the recipient for practice professional engineering or land surveying. A $5 annual renewal fee for certificates is required.

Penalties are provided for violation, which is classed as a misdemeanor; either a fine not to exceed $500 or imprisonment not to exceed three months, or both.

The bill exempts United States Government engineers, etc., and in addition all architects who may be registered under an architects' law. Licensed engineers are exempted from provisions of any act for licensing architects, so far as the term "buildings" in such act may include or be included in the structures enumerated in this proposed act.

Concrete Box Flume Carried Across Gulch on Trestle

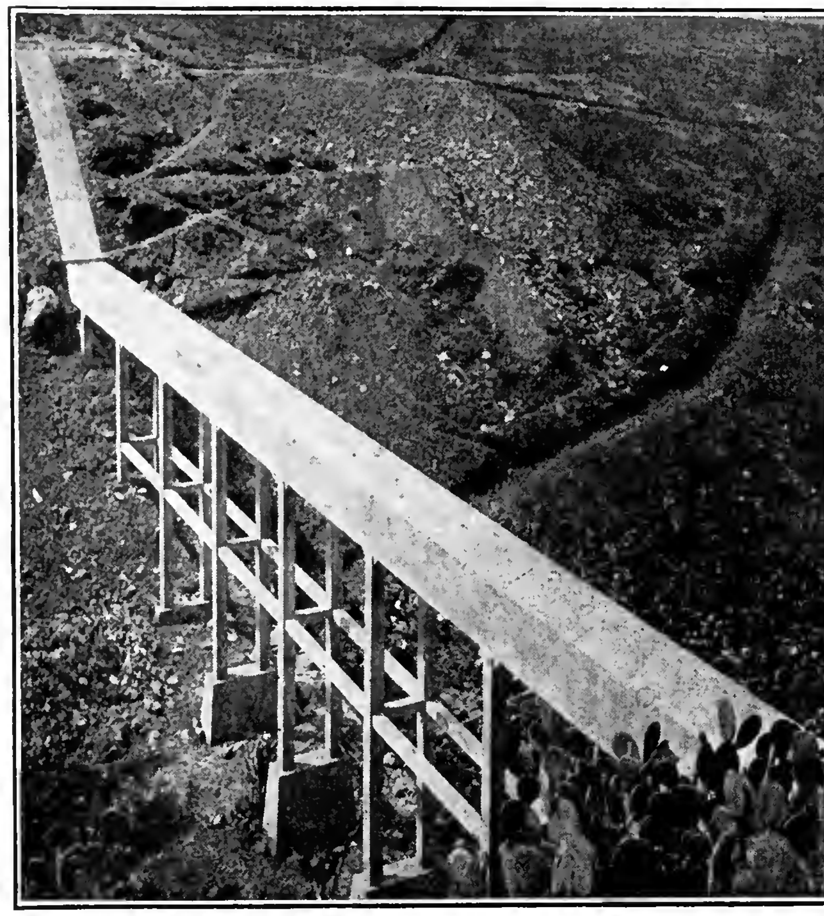
Irrigation System in Hawaii Substitutes Concrete for Steel Which Has Been Customary Material for Such Crossings

By A. W. Collins

Engineer for Maui Agricultural Company, Paia, Maui, T. H.

War embargoes on steel, and particularly on plate steel, in the Hawaiian Islands have forced the sugar plantations to substitute other materials in such structures as have been built of steel. The irrigation flume shown in the accompanying view and drawing is an example of such substitution.

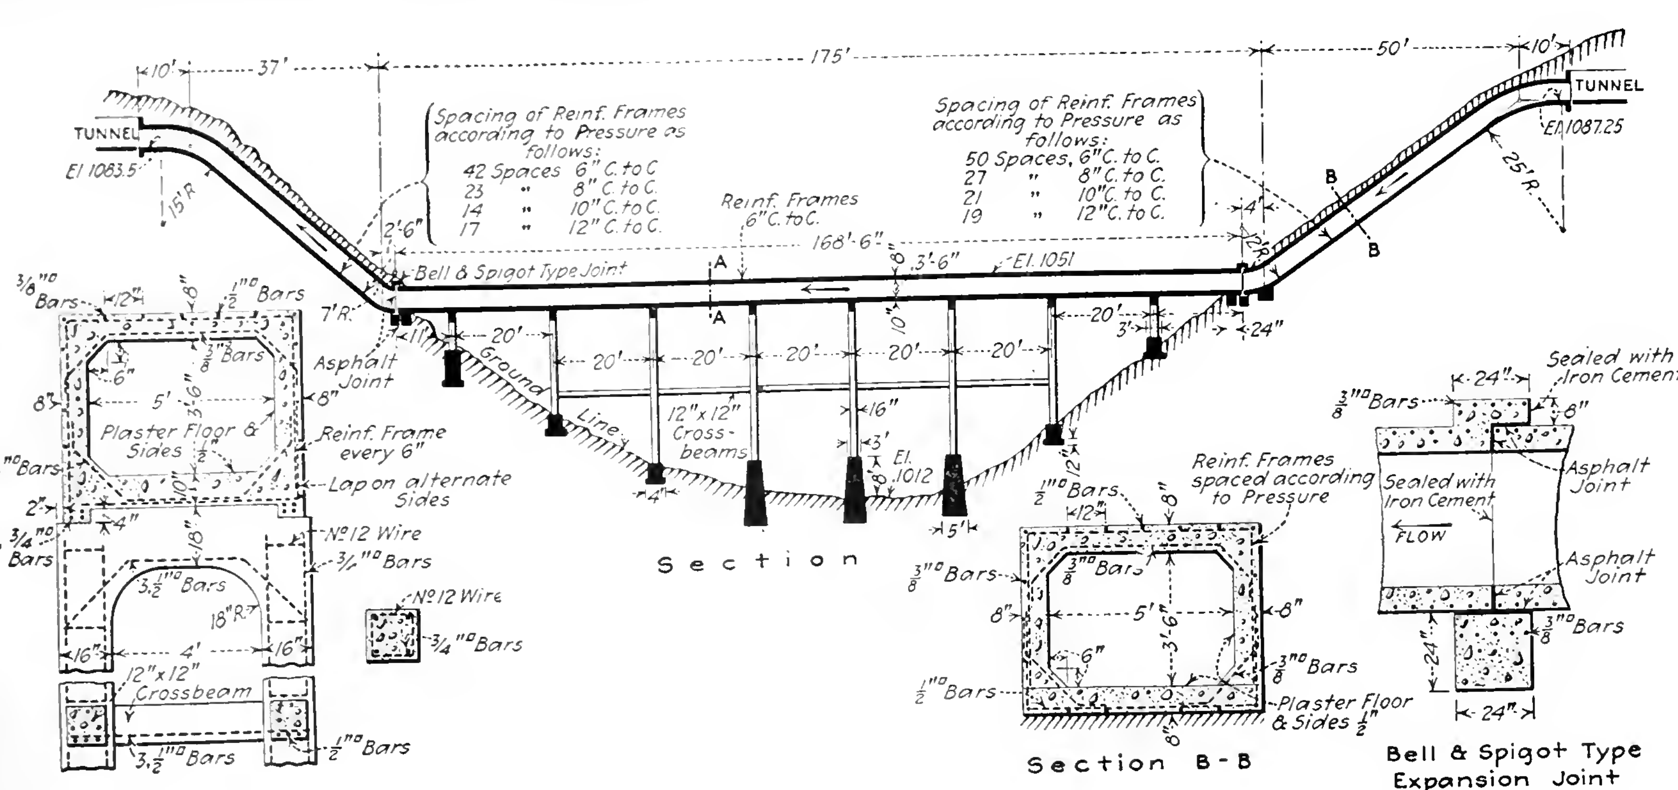
The topography of the Island of Maui is such that there are many box-like gulches running to the sea. These gulches are from 50 to 900 ft. in depth, and require the extensive use of flumes and inverted siphons in the irrigating systems of the sugar plantations. Across one of these gulches, known as Kailua Gulch, an irrigation line was carried across on a reinforced-concrete pressure flume combining the features of an ordinary flume and an inverted siphon. The grade line



SIX-BY-FIVE-FOOT IRRIGATION FLUME IS CARRIED ACROSS HAWAIIAN GORGE ON A CONCRETE TRESTLE

of the intake is 75 ft. above the bottom of the gulch, and the floor of the flume is 36 ft. below the intake, leaving 39 ft. for flume columns and footings. The difference in elevation of the intake and outlet is 4 ft. As shown in the drawing, the flume itself consists of a rectangular box resting on concrete column bents reaching down to prismatic piers in the gulley bottom.

The inclined stacks and flume columns were poured previous to the flume box, a rectangular bell-and-spigot



DETAILS OF HAWAIIAN IRRIGATION FLUME OF REINFORCED CONCRETE

expansion joint being constructed at the back end for connecting the stack to the flume. The flume itself was poured monolithically in 18 hours' continuous work. The steel plates inserted between the stack and flume at the expansion joint were later withdrawn, and the space was filled with an asphaltic cement poured hot. This joint has been under pressure for a number of months, but shows no leakage except some dampness on the outside.

Hydrated lime to the amount of 12% by weight of the cement was used in the concrete. No leakage of the flume or stacks has occurred except by sweating. The labor was entirely performed by Japanese, an American foreman being in charge of the work.

After-War and Motor-Truck Problems Hold Attention of Road Builders

How properly to connect up our national highway system, furnish labor for its construction, and decide upon the quality of the materials to be used for surfacing to support the heavy truck traffic which it must carry, were subjects discussed at the recent meeting of the American Road Builders' Association. These points are emphasized in the following abstracts of papers which created considerable discussion.—EDITOR.

Efficiency of Bituminous Surfaces Under Motor-Truck Traffic

BY PRÉVOST HUBBARD

Chemical Engineer, United States Bureau of Public Roads

FROM experience with pre-war traffic conditions many engineers had classified the various types of pavements with relation to their efficiency under the ordinary variations in traffic encountered on county, state and municipal highways. Their ideas were fairly well fixed on the subject, as was evidenced by more or less consistent practice in their choice of types when reconstruction or new construction became necessary. Just where the dividing line should be drawn between different types of pavements has always been a matter of individual opinion, but in general, with increases in volume and weight of traffic, the increasing efficiency of the bituminous types has been rated as follows: (1) Bituminous surfaces; (2) bituminous macadam; (3) bituminous concrete; (4) sheet asphalt and asphalt block.

Suddenly, and with little opportunity for anticipation, a very large mileage of our important state highways and many of our local county and municipal pavements were subjected to a tremendous increase in heavy truck traffic. This, coupled with an unusually severe winter, and immediately followed by war restrictions and other difficulties, created a serious situation and hundreds of miles of roads of all types failed within a comparatively few weeks or months. These failures were not only sudden but complete, and almost over night an excellent surface might become impassable. Such rapid and complete failures in municipal pavements were of less common occurrence, and as sheet asphalt and asphalt block have always been largely confined to municipal work, failure of these types have not been noted to the same extent as those of the other types mentioned.

In the haste and confusion of war activities, little opportunity has existed for a systematic and comprehensive study of the problem suddenly thrust upon highway engineers. Reports from all parts of the country have, however, established one outstanding fact which has a most important bearing upon any consideration of the efficiency of bituminous surfaces and bituminous pavements. A very large proportion of the failures have been characterized by an almost simultaneous destruction of the entire road structure. When not only the surface but the entire structure fails suddenly, inadequate subgrade or foundation conditions are primarily responsible, and but little basis exists for placing an efficiency valuation upon the wearing course.

Foundation failures in bituminous pavements may be due to one of two causes: Lack of thickness, or inability of the foundation structure to sustain the loads without appreciable internal movement. So far as bituminous pavements are concerned, remedy of the first cause does not affect the general type of construction; but the second cause may have a direct bearing upon possible modifications in design. There is practically no beam action in a broken stone or gravel foundation, and a load applied to the bituminous surface is transmitted quite directly to the subgrade. This load may be so great as to cause an internal movement sufficient to produce disintegration of the pavement.

EXPERIENCE ON CITY STREETS AS GUIDE

In general, experience on heavily traveled city streets has demonstrated the necessity of a slab foundation for any wearing course, and there appears to be no reason why such experience should not serve as a guide for new construction on heavy-traffic state and county highways. With respect to existing gravel and macadam roads, it would seem far safer at the present time to attempt to preserve them under heavy motor-truck traffic by means of surface treatment with bituminous materials, rather than to utilize them as foundations for the construction of new bituminous macadam or bituminous concrete pavements.

Under the same conditions of traffic, bituminous surfaces are most efficient in localities where frost action is either absent or not severe. Such treatments, used in connection with gravel roads adjacent to Army cantonments in the far South, have given reasonable satisfaction even under heavy motor-truck traffic. North of the frost line, and particularly in connection with the treatment of clayey gravel roads which become soft during the spring months, bituminous surfaces are apt to disappear completely. If, however, the gravel road is maintained by dragging and at the end of the thawing-out period is reshaped, thoroughly compacted and again treated with bituminous material, it may be kept in a reasonably satisfactory condition. Under very

heavy motor-truck traffic, however, maintenance costs may be extremely high, so that if a continuation of such traffic is to be expected the construction of a new road may be necessary.

Bituminous surfaces on properly constructed macadam roads subjected to heavy motor-truck traffic may, as a rule, be maintained in localities north of the frost line with less expense and better results than on gravel roads under the same conditions. Such surfaces, under heavy motor-truck traffic, cannot be considered as economical from the ordinary standpoint, but may prove the most efficient temporary method of preserving the existing road until money is available for reconstruction. It is believed, however, that they will not prove efficient unless constantly maintained by a patrol system operating throughout the year. This has been proved on maintenance by the Bureau of Public Roads of experimental bituminous surfaces on the Rockville Pike, Maryland, which is a macadam road having an average traffic of 135 motor drays, 816 motor pleasure vehicles, and 81 horse-drawn vehicles per day during the past year.

With regard to the efficiency of bituminous macadam under heavy motor-truck traffic, there are a number of points to be considered. In general, bituminous macadam has not been thought to be capable of carrying such traffic but, on the other hand, it has almost invariably been placed upon a broken stone or gravel base. Results obtained in the City of Alexandria, Va., by E. C. Dunn, city engineer, indicate that the bituminous macadam, if properly constructed and laid upon a concrete base, may prove quite satisfactory.

The efficiency of bituminous-concrete, sheet-asphalt and asphalt-block pavements under city traffic is so well understood as to require little comment in this paper. If they are laid upon suitable concrete foundations, there is no reason to suppose that the results will not be duplicated on county and state highways subjected to heavy motor-truck traffic. If the foundation is inadequate to support the load, the pavement is bound to fail, but, as previously pointed out, failure cannot then be considered a measure of efficiency of the pavement surface proper.

Materials of Construction and Efficiency

With regard to materials of construction a few comments may not be out of place, as the efficiency of a bituminous surface or bituminous pavement depends not only upon its method of construction but of what materials it is composed. In general, the author's observation and experience has been that the most efficient bituminous carpets are constructed with the heaviest grade of bituminous material which it is possible to apply and make adhere uniformly to the road surface. On old macadam roads it is advisable to keep the thickness of carpet under ½ in.; on certain types of soft gravel it may be of greater thickness, provided there is used a hard and tough coarse-aggregate cover of sufficient size to force into the old gravel surface by rolling. For clay-gravel or sand-clay-gravel roads north of the frost line, it is believed that light superficial treatment with bituminous materials applied cold will prove more efficient than the construction of a bituminous carpet, although neither will be adequate to carry the road through winter.

With regard to bituminous macadam and coarse-aggregate bituminous concrete, there is little to suggest in connection with the grades of bituminous materials ordinarily used. It is believed, however, that even in the northern United States the use of an asphalt cement softer than 120 penetration or a refined tar of less than 120 sec. float test at 50° C. for bituminous macadam is inadvisable if modern heavy motor traffic is to be sustained. It is also believed that more attention should be given to specifying and securing a uniform size, and grading within reasonable limits, of coarse stone, in order to promote uniformity in the penetration of the bituminous material as it is applied, and to produce a surface that will wear as uniformly as possible.

Thickening of Binder Course Desirable

In connection with sheet asphalt and the fine-aggregate bituminous concretes, the tendency to use harder grades of asphalt cement than heretofore used may prove advisable for very heavy traffic conditions. It is quite possible, however, that better results may be secured by a reduction in the compacted thickness of such pavements, with a corresponding increase in thickness of binder course where one is commonly used. For fine-aggregate bituminous concretes which are commonly laid without a binder course, the introduction of such a course not less than 1½ in. thick may prove advisable, with a reduction in thickness of wearing course to not more than 1½ in. Provided the binder course is properly constructed, such practice should tend to produce a pavement less susceptible to displacement under heavy truck traffic. It is believed that even more attention should be paid to aggregate grading than heretofore in order to produce most satisfactory results.

State, City and County Road Systems Should Be a Unit

By Nelson P. Lewis
Chief Engineer, Board of Estimate and Apportionment, New York City

The need of some kind of system in city streets is universally recognized; that is, the need of a primary system of main thoroughfares by which traffic is enabled to reach any part of the city from any other part with economy of distance and time. The need also of suitable connections between this primary street system and the chief highways traversing the immediate surroundings of the city, or reaching nearby places of interest and recreation, while more slowly realized, is quite apparent. The interest of the city, the county or the state is still largely confined to the system of streets or roads under the jurisdiction or control of these several units, and they have not been regarded as one great system of vital interest to all the people.

This lack of coördination is not a fault peculiar either to the city street system or the rural highway system, but is apparent in both. Rural highways connecting more or less important centers of population are generally much older than any part of city street systems,

except those in the oldest parts of the towns. It might have been assumed that the traffic between these centers of population would continue to follow these old routes, and yet how often it is found that they are reached only through streets of minor importance, often shabby and unattractive, not infrequently by means of awkward and obscure offsets, so that the dominant feeling is one of relief in leaving them or of extreme unpleasantness in entering them.

On the other hand, when a county or state road system is being improved, an increase in the width of such road as it approaches the city, the improvement of its alignment and grades, special attention to its cross-section and drainage, the planting of trees, etc., would be of incalculable benefit and involve little additional cost. Of course, this requires vision, a quality all too rare, and it may even involve the diversion of traffic through bypasses about already existing centers There are abundant instances showing what is daily lost through confusion or lack of traffic capacity at certain points along important highways.

The value of a trunk-line highway is generally in proportion to its length, provided it is well improved throughout. There are cases where an important state highway has been improved for long distances on both sides of a town and up to its corporate limits, but the town is not disposed to undertake a similar improvement of the portion of the road within its limits. The state may have the right to, and in equity it should, bear a certain portion of the expense, this portion depending upon the width at which the highway is to be improved through the town as compared with the width of the part outside of the town, but there may be no way of compelling the town to do its part. The result may be a delay of years in the realization of the benefit which would result from the complete improvement of the road.

State Should Have Power to Build Through Towns

It is probable that many of the state highway laws determine the proportions of the expense of improving such a link in its road system, which should be borne by the state and the town, but there may be no means of securing prompt action by the town authorities in providing its share of the funds. Such laws, where they exist, are necessarily uniform and inelastic; but even this is better than would be the practice of enacting special laws to fit each case. This would result in endless log-rolling, unfair compromise and grave abuse. It is difficult, if not impossible, to standardize where conditions are quite different. Prompt improvement of the entire trunk highway is the object to be sought.

The state should be able to secure this result, but without injustice to communities where the imposition of the share of the cost determined by statute would involve serious hardship. It would seem as though the power to carry out such improvement at the time other sections of the road are improved should be vested in the state, and that the town should be obliged to contribute such share as may be designated by law, with the right of appeal to some high judicial body which would have the power either to decrease or increase the proportion fixed by statute, after careful considerations of all the circumstances.

This suggestion may be somewhat crude, but it is put forward in the belief that the conditions which it is designed to meet are a serious obstacle to the prompt realization of a complete scheme of state and national highway improvement, and also in the belief that the value of such a system is dependent in no small degree upon the promptness with which it can be wholly completed.

Sources of Supply of Unskilled Labor for Highway Work

Committee Report by Chairman Paul D. Sargent
Chief Engineer, Maine State Highway Commission

After correspondence with members of your committee, it seemed advisable to approach this question from three directions: First, to learn if possible the condition of the unskilled labor market in the years immediately succeeding the close of the Civil War; second, to make a limited survey of labor conditions as they have affected highway work during the past few years and attempt to estimate probable labor conditions during the coming season; third, to get such information from the United States Department of Labor as has a bearing on this question.

Meager statistics contained in a letter of Charles B. Baldwin, acting commissioner of labor statistics, under date of Jan. 30, 1919, gives all of the information which your committee has been able to obtain concerning labor conditions after the close of the Civil War. This letter shows that while conditions were not good, times could not be called hard, and business remained good until the panic of 1873. Little unemployment was reported.

A questionnaire was sent out to all state highway departments, to the city engineers of all cities having a population in excess of 100,000, and to many of the large road-building contractors throughout the country.

The questionnaire asked for information as to the number of hours for a day's work, the rate of pay per hour for common labor from 1912 to 1918, and what would be the probable rate for common labor for 1919, 1920 and 1921. Inquiry was also made as to the apparent available sources of supply of common labor for the present season; as to additional sources of supply, if there did not appear to be a sufficient supply in sight, and whether state labor exchanges had been used where established, and with what result. It concluded by asking for information as to the number of common laborers required for construction work during the season of 1919.

Replies from Three Sources of Information

From the replies, which have been tabulated, we extract the following information:

Replies from State Highway Departments—Thirty-nine state highway departments made replies to our questionnaire. As some of the departments are only two years old, we have not used their replies in figuring average rates of wages.

In 1912 the average rate per hour as reported by 27 states was $0.188, while in the same year Georgia was paying $0.09 and Nevada was paying $0.40. Only six states were paying $0.25 or more, and 10 states were paying $0.15 or less—most of them less. In 1913

the average, as reported by 28 states, was $0.20. In 1914 the same states reported an average of $0.205, in 1915 of $0.225, in 1916 of $0.2585, in 1917 of $0.303 and in 1918 of $0.39. The highest rate for 1918 is reported by Oregon at $0.58, while the lowest is by South Carolina, at $0.18 per hour.

Twenty-seven states reply to our question as to probable wages in 1919. The average of these replies gives a rate per hour of $0.352; which, compared with the average of $0.39 for 1918, shows a slight decline. Fifteen states think the rate for 1921 will be slightly less than in 1920.

Thirty states think labor supply will be more plentiful in 1919, 1920 and 1921 than during the past three years. Twenty give as their reason the ending of the war with return of soldiers, closing of war industries and munitions plants, stopping of shipbuilding, etc. Seven states report an oversupply of labor now.

Fourteen states have state labor exchanges. Five states have obtained labor through these exchanges, but only three report good results. Twenty-eight states estimate their requirements of common labor for 1919 as 160,900 men.

Replies from Cities—Fifty-four out of 82 cities have replied to our questionnaire. Forty-six furnish information as to wages for all years from 1912 to 1918. Taking the year 1912, Spokane, Wash., reports $0.375 per hour, which was the highest, and Birmingham, Ala., with $0.14, was the lowest, while the average rate for the year was $0.234. In 1913 these 46 cities report an average wage of $0.238 per hour. In 1914 the average was $0.245, in 1915 $0.255, in 1916 $0.276, in 1917 $0.312, in 1918 $0.384. Boston, Mass., reports the highest rate for 1918, at $0.525 per hour. San Antonio, Tex., had the lowest for the year, $0.25, while Atlanta, Ga., and New Haven, Conn., both report a wage of $0.28.

Average Wage and Supply of Labor

The average wage which 48 cities expect to pay in 1919 is $0.384, which is the same as the average for 1918. Forty-two cities expect labor to be more plentiful this year than last, and 28 of the cities give as a reason the termination of war, the closing of war industries and the return of soldiers. Sixteen cities report plenty of labor now and in sight. Only two cities suggest additional sources. One New York city thinks immigration should not be prohibited, and one California city suggests Mexican labor. Three cities have obtained labor from state labor exchanges with good results; seven have had poor results with such labor.

Thirty-nine cities report that they will need 19,160 laborers during the season of 1919. Forty-three report that they will spend $46,570,613 in highway and street work.

Replies from Contractors—Twenty-four contracting firms, well distributed throughout the country, make replies which may be summarized as follows:

The average rate of wages they paid in 1912 was $0.192; in 1913 it was $0.20; in 1914, $0.21; in 1915, $0.23; in 1916, $0.256; in 1917, $0.315; in 1918, $0.397. The average wage which they expect to pay in 1919 is $0.38.

Sixteen contractors expect labor to be more plentiful on account of the cessation of war activities and the return of soldiers. It is interesting to note that just half of these contractors suggest immigration as the source of further labor supply.

Nine contractors have used labor from state labor exchanges. Six report "poor" results; one reports "bad" results, and two state that results were indifferent.

Information from United States Department of Labor

Through its employment offices distributed throughout the country, the Department of Labor has kept close tab on employment conditions, beginning soon after the signing of the armistice, and the number of cities reporting unemployment has been growing weekly. From Otto T. Mallery, executive secretary of the War Labor Policies Board of the United States Department of Labor, it was learned that this board is rather apprehensive of a serious condition of unemployment. The director of the board, Harold G. Moulton, concludes that, during the next 12 months, it is probable 5,000,000 or 6,000,000 workers will seek employment in this country.

As many of the industries which would under peace conditions absorb these laborers were dismantled and refitted for war work, and as many new plants were built in the early months of the war and fitted for war work exclusively, and will now have to be refitted for peace-time production, it is apparent that there may be some hiatus in employment, unless public works of a large volume can be provided to consume this labor during the process of transition.

It is interesting to note, in a recent report of Mr. Mallery, the following list of activities suggested for providing employment for surplus labor: (1) Highways; (2) forestry; (3) water conservation and control; (4) health; (5) public works of cities and towns. Note that highways are placed first. The following explanatory statement is interesting:

"Highway construction is particularly useful in providing employment for unskilled workers, upon whom the greatest burden of suffering falls in bad times. The geographical distribution of highway work is another element of advantage for our purpose, because it will diminish unemployment in many districts at the same time." Mr. Mallery states that the road builders of the country should rest assured that plenty of common labor for all highway construction work will be available during the present season, and from its investigations your committee concludes that the 1918 wage rate will be slightly lowered.

Vitrified Brick Construction for Heavy Motor-Truck Traffic

By Major W. M. Acheson
Division Engineer, New York State Highway Department

Brick pavement construction since 1915 has been subject to far greater changes in design than any other type. These changes, through a more rational use of the same amount of material, have tended to greater strength and durability. Engineers are now giving special attention to the various details of the

pavement, such as a foundation, a bedding course, and a wearing surface, in order to meet the existing conditions due to heavy motor-driven traffic.

In present practice, the foundation course is usually made of cement-concrete, of proportions from 1:2½:5 to 1:3:6, the thickness depending largely upon the character of the subsoil and the amount of traffic. While cement-concrete foundations predominate in brick pavements, many miles have been laid on foundations of compact sand, gravel and broken stone. However, engineers will agree to the absolute necessity and economy of concrete in the foundation for brick and all types of block wearing surface, together with mixed types of bituminous pavement. In fact, the time is here when highway engineers are called upon to design rigid types of construction. Too great care cannot be exercised in the proper design and construction of the foundation.

Sand cushion was originally intended to serve the double purpose of providing a uniform bearing for the wearing surface and a resiliency to absorb the impact of traffic However, it has been found impossible to obtain uniformity, even though this bed was reduced from 2 to 1 in., due to the variation in moisture content and thickness, which causes unequal shrinkage, thus defeating the function of providing a firm, uniform bearing for the wearing surface and causing failure under heavy traffic. Another defect is that the sand cushion works up between the joints of the brick, thus preventing the proper penetration of the filler. It is the opinion of the writer that the day of sand cushion for grouted surfaces has passed.

Brick Pavements of Semimonolithic and Monolithic Construction

To overcome these difficulties, which all precautions in laying the sand cushion have not sufficed to eliminate, the laying of the bricks upon a cement-sand bed, known as semimonolithic, or upon a green concrete foundation, which is known as monolithic, has been resorted to.

In the semimonolithic type, the proportion generally used for the bed is three parts of sand to one of cement. It is the practice to machine mix these materials while dry. In spreading upon the base, care should be taken to get uniformity; but hand rolling is not deemed advisable as it makes too dense a bed and it is hard to obtain a smooth surface by rolling. The thickness advocated is a minimum of ¾ in. and a maximum of 1 in. Immediately preceding the grouting of the brick surface, the bed should be thoroughly saturated with water.

Brick pavements with cement-sand bed were built at Baltimore as early as 1906, and adopted as the city's type of construction in 1915. It was used in Jacksonville and also in the ramps of the Pennsylvania R.R. station in New York in 1910. (See *Engineering News-Record* of Feb. 20, 1919, p. 378.)

With present methods the semimonolithic type is better adapted to wide streets than is monolithic, but where widths are not over 24 ft., so that a templet may be used to shape the entire crown, the monolithic type of construction may be used. Proper consistency of concrete foundation is essential for this class of construction, and care should be taken to spade properly and distribute the concrete to prevent waves in the finished surface due to the difference in density. The foundation is spread usually ½ in. thick and formed by using a tamping templet, which brings the mortar to the surface, thus forming a bed for the brick. A mechanical templet has been developed which consists of a gasoline engine mounted on a cross-frame, with wheels which rest upon the side forms. This power templet performs the double purpose of tamping and smoothing the concrete, giving it greater density. It moves at the rate of 4 ft. per minute and can be adjusted to various widths. For rolling the wearing surface of the monolithic type, the use of a hand roller about 30 in. long, 24 in. in diameter, and weighing from 600 to 900 pounds, is advocated.

The advantage of these monolithic types of construction is that they overcome defects of the sand cushion, insuring rigid construction. The cement-sand bed practically unites the wearing surface with the concrete foundation and assures a proper penetration of the grout, thus giving a perfect bond for the full depth of the brick.

Both of these types largely eliminate the hollow rumbling noise which is common with sand-cushion construction, and give a more economical and scientific design in that a stronger slab is provided with the same amount of material. The use of the monolithic type also permits of the elimination of the edging, thus reducing the cost.

Wearing Course

Monolithic types have tended to develop the use of paving brick of less thickness, which will result in more economy, one of the important features being the saving in transportation charges. There should also be an economy in the first cost, together with a saving in actual manipulation.

The standard paving brick of today is 3½ in. wide by 8½ in. long by 4 in. deep, laying 40 to the square yard. They are provided with spacing lugs of either the repressed or the wire-cut lug type, the latter having rapidly increased in favor with paving engineers and being now extensively specified. The fiber sides of wire-cut lug brick which are produced by the method of manufacture give a greater bond strength, the uniform lugs insuring a thorough and even penetration of filler and the square edges making it easy to obtain flush joints which do not cobble, thus giving a smooth wearing surface.

Two classes of joint filler are used to bind the brick units together, the cement-grout filler and the bituminous filler. The experience and observation of the writer are that the results from the cement-grout filler are superior to those with soft filler, and it is absolutely necessary in the modern semimonolithic and monolithic types of construction. The New York State specifications for cement grout filler allow the use of one part cement to two parts sand when machine mixed, and one part cement to one part sand if hand mixed. Machine mixing is considered far superior to hand mixing, and is more economical.

Health Board Studies Pipe Corrosion in Buildings

Cast-Iron Vents Have Long Life but Increasers Required at Roof Cause Rusting from Stoppages—Wrought Iron Preferable to Steel

EXAMINATIONS of sewer- and vent-pipe systems in buildings of various ages in the Chicago business district, made under the supervision of Thomas J. Claffy, assistant chief inspector of the sanitary bureau of the Chicago Health Department, have disclosed satisfactory service from black and galvanized steel pipe for a period of from five to 15 years. Wrought-iron and cast-iron vents in installations more than 20 years old are 20 and 25%, respectively, destroyed, while steel vents were 90% destroyed in the same periods. Mr. Claffy gave the information in a paper presented before the American Society of Sanitary Engineers, from which the following notes are abstracted.

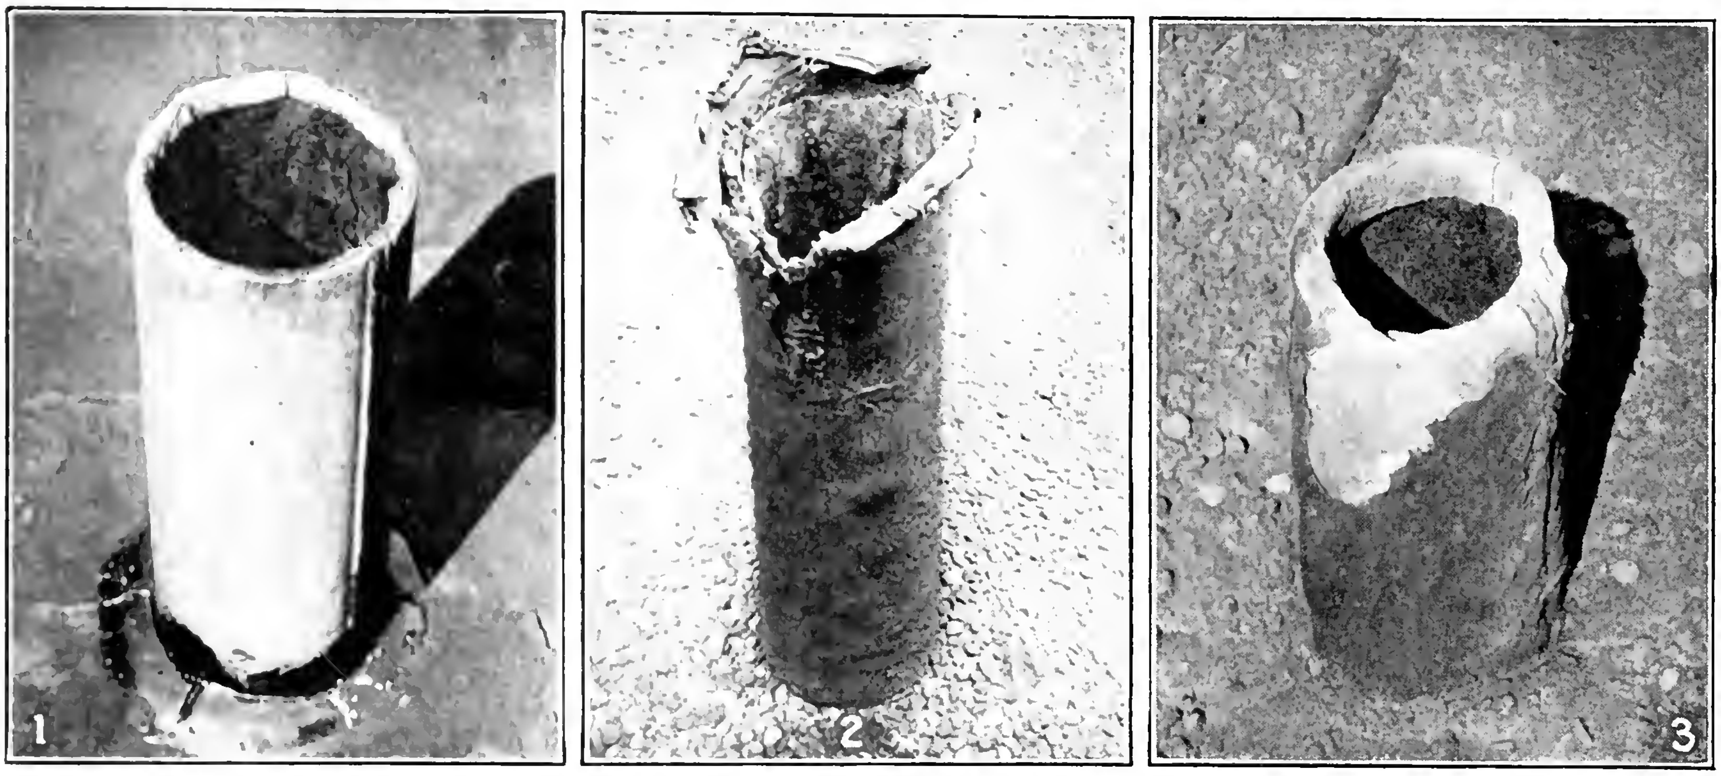
It was the aim to examine buildings of six stories and higher, and more than five years old. In making this investigation the inspector was required to report on the height and age of each building; the number of vents at the roof line; the size of pipe and whether cast-iron or screw-joint; also to obtain samples of pipe and to describe such conditions as were found. Photographs were obtained of sufficient vents on the roofs to show an existing average of their condition. The inspector also was required to state whether the owner, superintendent, engineer or other person was interviewed. To distinguish between wrought-iron and steel pipe, it was necessary to take samples, filings being obtained of the clean metal for chemical tests, and pieces of the pipes for fracture tests.

Of 63 buildings investigated, 11 were less than eight years old, while 52 ranged between 10 and 30 years. Classified according to kinds of pipe used, 15 had cast iron; eight wrought iron; 19 steel; 11 mixed wrought-iron and steel; 10 cast-iron mixed with wrought-iron or steel. In the pipe systems more than 20 years old 33 roof terminals were of steel and were practically all destroyed; of 155 wrought-iron vents 17 were nearly destroyed, and of 218 cast-iron vents 43 were nearly destroyed. The relative estimated per cent. of destruction for steel, wrought iron and cast iron was 90, 20 and 25.

The poorer rating for cast iron in comparison with wrought iron is to some extent due to the probably higher average age of the cast-iron installation. The comparison refers only to destruction or near-destruction by corrosion, and does not take into account several dozen cast-iron vents which had clogged up with rust at the increaser below the roof and had thus become temporarily useless. Neither does it take into account the condition of the joints, which would further improve the rating of wrought iron over cast iron. The steel pipe was so completely destroyed by corrosion after 20 years as to exclude all consideration of joints or clogging which might be figured in its favor.

In buildings from 10 to 19 years old the large number of steel installations indicate how completely steel pipe, on account of its slightly lower first cost, has come into use in Chicago. On 101 galvanized steel vents 25% of the galvanizing was destroyed; of 144 black steel vents all were "scaling badly," and the depreciation was estimated at 75%. Of 28 wrought-iron vents, both black and galvanized were in "good" condition, the black being estimated at 10% "depreciation." All of the 13 cast-iron vents were in "good" condition, but with an estimated 10% "depreciation."

Galvanizing on the steel pipe appeared to be partly or wholly destroyed before the pipe is 15 years old, the pipe as a result lasting from 15 to 25 years before com-



LEAD SHEATH PROTECTION ON VENTS SAVES OUTSIDE FROM COMBUSTION GAS CORROSION

Fig. 1—Galvanized steel vent seven years on City Hall scaling badly. Fig. 2—Black steel vent 16 years on the National Life Building crumbles in the hand. Fig. 3—Black wrought iron 27 years on Tacoma building is pitted as if by heavy sand blast

plete destruction is observed. The relatively good condition of wrought iron, both black and galvanized, should again be noted, the 10% given for both wrought iron and cast iron indicating a slight depreciation but no actual failures.

Severe corrosion of steel pipe becomes evident even before the building has passed its first decade. Notable examples are the Cook County Building, 10 years old, with 34 steel vents, about half of them galvanized; and the City Hall, seven years old, with 42 steel vents, all galvanized but, in spite of this, all scaling severely. This does not support the claims concerning the improvement of steel pipe in recent years, according to Mr. Claffy, for, if anything, these new installations seem to be relatively worse than the older ones.

Although corrosion of drainage piping is severe everywhere, it appears to be about 50% worse in Chicago than in New York and other cities. Mr. Claffy attributes this largely to the fact that sewers are too small and remain full of water well beyond midnight, and the small-sized vents and wastes result in blowing out of trap seals and in siphonage of fixtures. The flat topography of the city, making possible only flat grades, tends to produce a septic condition and also accentuates the concentration of gases arising therefrom. This sewerage condition caused the main house trap to be abandoned long ago, the sewers and house drains being ventilated through the plumbing system.

If the destruction of the different pipes mentioned were confined to the roof line or the space immediately below it, there might be some grounds for believing that sulphuric acid gas from burning coal might be the destructive element. This, however, is not the case. In the Borland Building the soil, waste and vent pipes at the third and fourth levels were entirely rusted away, while the same lines of pipe near the roof were practically as good as when installed. In the Unity Building a wrought-iron waste line from urinals was rusted out entirely from the third floor up.

In the reconstruction of bath rooms in the Great Northern Hotel, about 10 years ago, it was found that the old system of waste and vent pipes was entirely destroyed at the threads and over practically the entire length of the pipe in many places. In other instances, drains hanging from the basement ceiling had rusted through and had to be replaced, and branch soil and waste pipes on intermediate floors were subject to the same deterioration from internal corrosion. For this reason, Mr. Claffy holds, it is clear that the agency causing corrosion is not from the atmosphere above the roof, but is due to the gases developed within the plumbing system itself and from the sewer in the street.

City ordinances in Chicago require the size of vents and soil stacks to be increased from a point directly below the roof to the top of the pipe, so as to prevent hoar frost from closing up the pipe in cold weather. Unfortunately, this causes rust and dirt falling down the pipe to find lodgment at the increaser, clogging up the pipe and defeating the purpose of the ordinance. This tendency to clogging is noticeable everywhere, even in cast- and wrought-iron pipe installations. The type of fitting now used as an increaser has a more gradual taper than that formerly in vogue, but the tendency to clogging can hardly be eliminated. The remedy would seem to be in the adoption of larger sizes of pipes, all the way down through the building, while if increasers are used they should never be over 1-in. taper. It would seem far better to have the hoar frost closing up the pipes for a few days in extremely cold weather than to have the pipes permanently clogged with rust and dirt.

From the standpoint of sanitation, one leaky pipe is as bad as another, regardless of what causes the leak, whether corrosion or failure from expansion and contraction. Many instances of leaky calked joints were observed, and unquestionably many escaped attention, being more or less inaccessible. Many joints also had been recalked, but it is a regrettable fact that leaky

EXPOSURE FOR THIRD OF CENTURY STILL LEAVES MUCH LIFE LEFT IN CAST IRON AND WROUGHT IRON

Fig. 4—Block wrought-iron vent 29 years on Bedford Building, although badly scaled and pitted, had to be cut with chisel for sample. Fig. 5—Heavy cast iron 30 years on McCormick Building only pitted deeply inside. Fig. 6—Medium or standard cast-iron vent on old Oxford Building cracked and pitted nearly through on one side

calked joints are not always readily discovered, and even less frequently repaired with promptness. In the meantime they permit the escape of gases of a noxious, if not dangerous, character. Unquestionably, from this point of view the screw joint is to be preferred, as long as it can be obtained without sacrifice of the necessary rust resistance of the pipe material.

If satisfactory service from black and galvanized steel pipe is obtained only for a relatively brief period of five to 15 years, and the ordinances do not differentiate between such pipe and wrought iron, Mr. Claffy believes that this is not playing fair with the public, which pays the bills. He says that the evidence against steel pipe is so indisputable as to admit of no contention. He is firmly convinced from what has been demonstrated in this investigation that there is a most decided difference between steel and wrought iron for such purposes as are necessary in a sanitary plumbing system. That fact should be recognized, and ordinances, laws or specifications should provide that steel pipe be not used in any buildings except those of a temporary character.

Arch Analysis by a Method Using Variable Elastic Weights

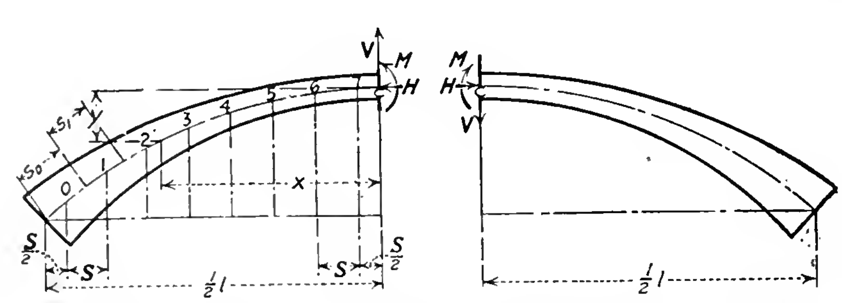
By Simplifying the Computation of the Summations Required, New Tabular Form Permits Rapid Solution of Arch Problem by Influence Lines

By F. J. Dulude
With J. G. White Engineering Corporation, New York

In analyzing arches with fixed ends by the elastic theory, it is customary to divide the arch ring into a number of sections such that the ratio of the length of each section to its moment of inertia is a constant; i.e., the elastic weight, s/I is a constant. This method is open to criticism on the score of inaccuracy and difficulty of application, as it gives excessively long sections near the springing and unnecessarily short sections near the crown. Since the moment of inertia varies very rapidly near the springing and very slowly near the crown, it is evident that, from the standpoint of accuracy, this arrangement of sections is exactly the reverse of what it should be. Again, the points at which the bending moment must be figured are inconveniently spaced for ease of calculation, having no relation whatever to the location of the loads, especially in the case of arches with open spandrels. This makes it difficult to apply influence line analysis for moving loads.

The method presented herewith consists in finding the horizontal thrust, bending moment and shear at the crown for a load unity at any point, from which H, M and V for any system of loads can readily be found. When these unknowns at the crown are determined, the true equilibrium polygon can be drawn and the stresses at any section computed. By dividing the arch ring into sections with equal horizontal projections, as shown, accuracy and simplicity of calculation are obtained, as can best be demonstrated by reference to the concrete example which follows.

Tables I and II give the complete solution of H_u, M_u and V_u at the crown for a load unity at 15 points, including the crown. It should be noted that of the 22 columns in these tables, only 12 involve multiplication or division, and of these 12 only four—namely, 6, 9, 12 and 13—involve the multiplication of one variable by another, necessitating a separate setting of the slide rule for each line. Columns 14, 15, 17, 18, 19, 21 and 22 can each be obtained by one setting of the slide rule, being the product of a constant by a variable. Columns 4, 5, 7, 8, 10 and 11 are obtained by addition. Columns 16 and 20 are obtained by subtraction and columns 1 and 2 are obtained by scaling. Column 3, which is a tabulation of the variable s/I, involves computation which must be made in any event, no matter which method is used.



ARCH TREATED AS CURVED CANTILEVER BEAM

The example has not been solved beyond finding H, M, and V at the crown for live and dead loads, because when these are known the problem becomes statically determinate and further solution presents nothing new.

The notation and working equations, including equations 4 and 5 for temperature change, are as follows:

Let H, H_u, H_t be the horizontal thrust at the crown

TABLE I—COMPUTATION OF REQUIRED QUANTITIES

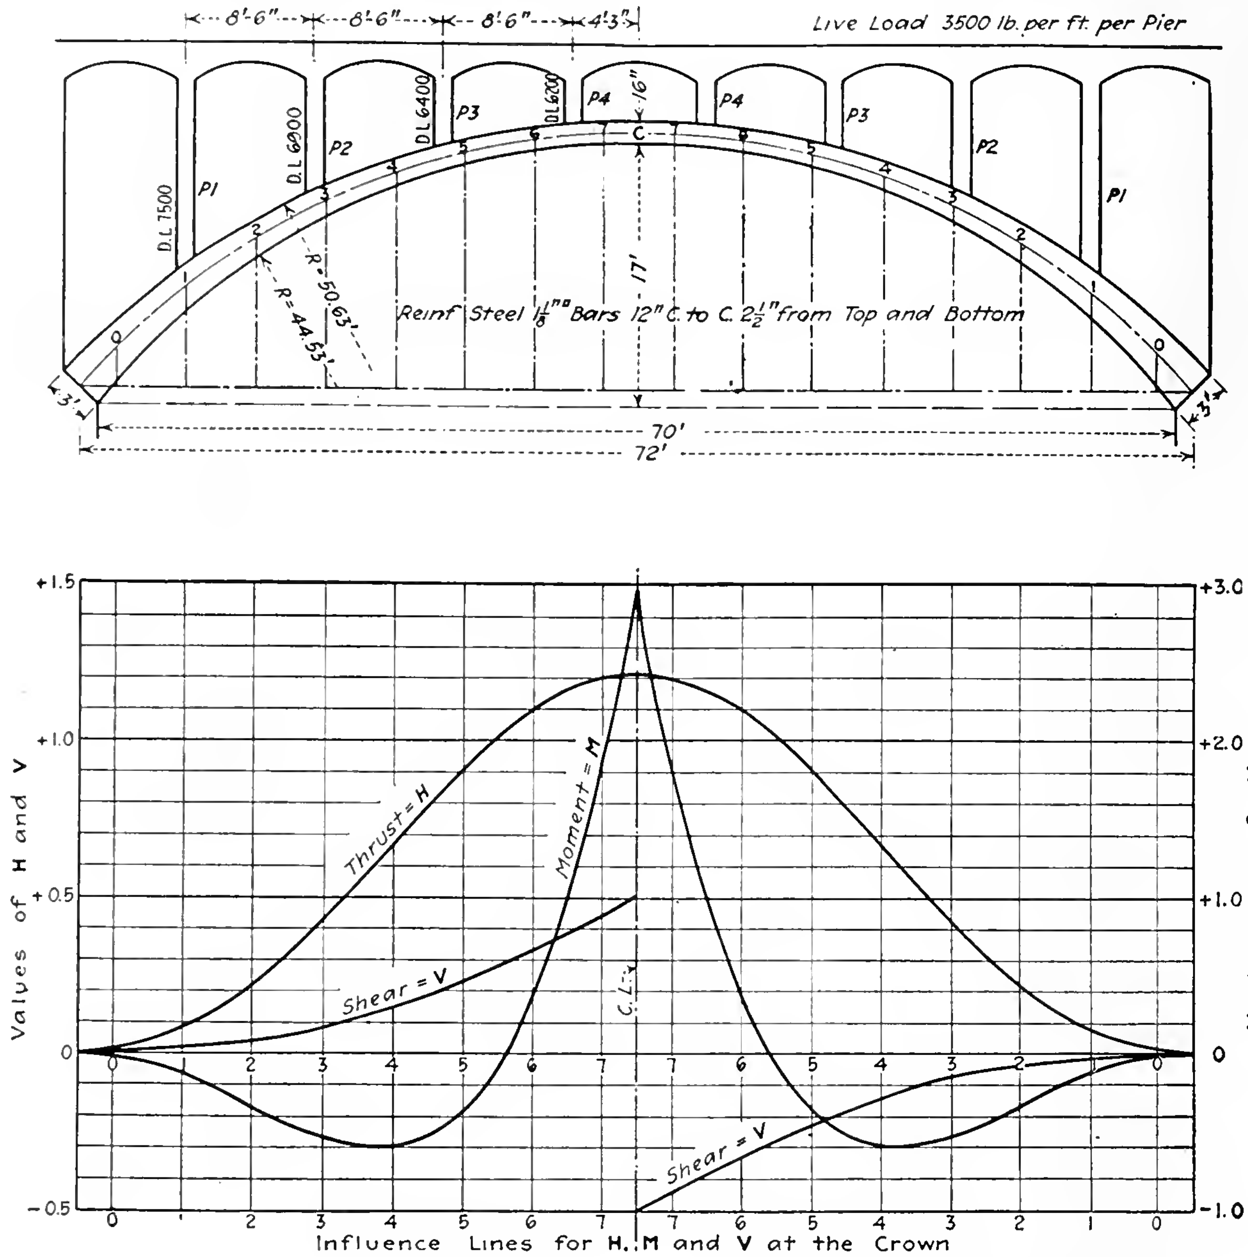
7	2.25	0.1	17.85	78.18	179.97	1.8	220.2	1,037.2	40.1	985.6	3,687.1	90	0.2
C	...		....	....	219.06*	...	.	*1,147.3	.....	.....	*4,180.0	.....	.....
Σ	.....		78.18	.....		220.2	..	....	985.6	....	....	18,815	1,614.0

*179.97 + ½ (78.18)   * 1,037.2 + ½ (220.2)   *3,687.1 + ½ (985.6)

due to live and dead loads, unity at any point, and temperature change respectively; M, M_u, M_t the bending moment at the crown due to live and dead loads, unity at any point, and temperature change respectively; V, V_u the shear at the crown due to live and dead loads, and unit load at any point, respectively; m the bending moment due to external loads at any point on either half of the arch considering each half of the arch as a cantilever, m_L for left half and m_R for right half; s the length of a division of the arch measured along the arch axis; I the moment of inertia of any section; $s/I = \Delta$ a variable having the value $\frac{s_0}{I_0}$ of pt. o, $\frac{s_1}{I_1}$ at pt. 1, etc.; x and y the coördinates of any point referred to the crown as origin; C the coefficient of expansion; T the temperature variation in degrees; E the modulus of elasticity of concrete; l the length of span, and S the horizontal division of span. M and V are assumed positive when acting as shown by the arrows in the diagram. Each half of the arch can then be considered as a cantilever subjected to exactly the same forces as exist in the arch itself; that is, the external loads, the reactions and the stresses at the crown represented by H, M and V. By applying the three fundamental equations of the elastic equilibrium to curved beams, it can be shown that:



SPANDREL ARCH OF 70-FOOT SPAN ANALYZED BY INFLUENCE LINES

$$H = \frac{\Sigma my\Delta\Sigma\Delta - \Sigma m\Delta\Sigma y\Delta}{2[\Sigma y^2\Delta\Sigma\Delta - (\Sigma y\Delta)^2]} \qquad (1)$$

$$M = \frac{\Sigma m\Delta - 2H\Sigma y\Delta}{2\Sigma\Delta} \qquad (2)$$

$$V = \frac{\Sigma(m_L - m_R)x\Delta}{2\Sigma x^2\Delta} \qquad (3)$$

$$H_t = \frac{CTlE\Sigma\Delta}{2[\Sigma y^2\Delta\Sigma\Delta - (\Sigma y\Delta)^2]} \qquad (4)$$

$$M_t = \frac{H_t\Sigma y\Delta}{\Sigma\Delta} \qquad (5)$$

The summations $\Sigma m\Delta$ and $\Sigma my\Delta$ are for the entire arch. All other summations are for one-half the arch.

The only really troublesome terms in the above equations are $\Sigma m\Delta$, $\Sigma my\Delta$ and $\Sigma(m_L - m_R)x\Delta$. But it will be shown that, for unit loads, these three terms can be obtained by the simple process of addition. By dividing the horizontal projection of the semi-axis into any number of equal divisions, S, the points, 0, 1, 2, etc., are located by verticals at the center of each division.

Now consider a load of unity at any point, say 7 for example. Then $\Sigma m\Delta = m_0\Delta_0 + m_1\Delta_1 + m_2\Delta_2 + \ldots + m_6\Delta_6$;
but $m_0 = 7S$, $m_1 = 6S$, $m_2 = 5S$ etc.: Therefore:

$$\Sigma m\Delta = S[7\Delta_0 + 6\Delta_1 + 5\Delta_2 + \ldots\ldots + \Delta_6] \quad (6) \ldots$$

similarly

$$\Sigma my\Delta = S[7\Delta_0 y_0 + 6\Delta_1 y_1 + 5\Delta_2 y_2 + \ldots + \Delta_6 y_6] \quad (7)$$

and

TABLE II—COMPUTATION OF H_U, M_U AND V_U

	8	14		15	16	17 H_U	18	19	20	21 M_U	11	22 V_U
	$[y\Delta]$	$[y\Delta]\Sigma\Delta$	$[\Delta]$	$[\Delta]\Sigma y\Delta$	$\frac{Q}{14-15}$	$S\frac{Q}{K}$	$S[\Delta]$	$2H_U\Sigma y\Delta$	$\frac{R}{18-19}$	$\frac{R}{2\Sigma\Delta}$	$[x\Delta]$	$\pm S\frac{[x\Delta]}{2\Sigma x^2\Delta}$
1	42.2	3,300	2.95	650	2,650	0.076	13.3	33	— 19.7	—0.126	99	±0.019
2	128.8	10,100	10.26	2,260	7,840	0.226	46.2	99	— 52.8	—0.338	326	±0.039
3	253.8	19,850	22.98	5,060	14,790	0.427	103.5	188	— 84.5	—0.540	688	±0.082
4	415.8	32,500	43.65	9,600	22,900	0.662	196.0	291	— 95.0	—0.606	1,209	±0.144
5	608.3	47,600	75.22	16,550	31,050	0.896	338.0	394	— 56.0	0.358	1,903	±0.227
6	818.8	64,000	119.64	26,300	37,700	1.091	538.0	480	+ 58.0	+0.371	2,742	±0.328
7	1,037.2	81,100	179.97	39,640	41,460	1.195	810.0	526	+284.0	+1.815	3,687	±0.441
C	1,147.3	89,700	219.06	48,200	41,500	1.200	986.0	528	+458.0	+2.930	4,180	±0.500

$K = 2[(1614 \times 78.2) + 220.2^2] = 155,600$ $\quad S = 36/8 = 4.5$ $\quad 2\Sigma\Delta = 2 \times 78.2$ $\quad 2\Sigma x^2\Delta = 2 \times 18,815$

$$\Sigma m x\Delta = S[7x_0\Delta_0 + 6x_1\Delta_1 + 5x_2\Delta_2 + \ldots + x_6\Delta_6] \quad (8)$$

For simplicity, designate the terms inside the brackets in (6), (7) and (8) by $[\Delta]$, $[y\Delta]$ and $[x\Delta]$. Then, for example, $[\Delta]_7 = [\Delta]_6 + \Sigma_0^6\Delta$, etc., since if $[\Delta]^n = [\Delta]$ for a load of unity at point n; $[y\Delta]^n = [y\Delta]$ for a load unity at point n, and $[x\Delta]^n = [x\Delta]$ for a load unity at point n, it can be shown that, in general:

$$[\Delta]^n = [\Delta]^{n-1} + \Sigma_0^{n-1}\Delta \quad (9)$$

$$[y\Delta]^n = [y\Delta]^{n-1} + \Sigma_0^{n-1} y\Delta \quad (10)$$

$$[x\Delta]^n = [x\Delta]^{n-1} + \Sigma_0^{n}\, x\Delta \quad (11)$$

From equations (9), (10) and (11) it follows that $[\Delta]$, $[y\Delta]$ and $[x\Delta]$ for all points can be obtained by successive additions beginning at point 1, where $[\Delta] = \Delta_0$, $[y\Delta] = y_0\Delta_0$ and $[x\Delta] = x_0\Delta_0$.

For a load of unity at any point, then:

$$H_U = S\frac{[y\Delta]\Sigma\Delta - [\Delta]\Sigma y\Delta}{2[\Sigma y^2\Delta\Sigma\Delta - (\Sigma y\Delta)^2]}$$

$$M_U = \frac{S[\Delta] - 2H_U\Sigma y\Delta}{2\Sigma\Delta}$$

$$V_U = \pm S\frac{[x\Delta]}{2\Sigma x^2\Delta}$$

V_u is positive for the left half of arch and negative for the right half of arch.

The tabular forms of computation have been applied to the 70-ft. arch span shown. The time required, after facility is attained, will be considerably less than that usually necessary by the current method, using the determination of arch divisions to give constant s/I.

The value of dead load H is found in the usual way by multiplication of loads and H_u to be 40,860 lb.; similarly dead load $M = -1480$ ft.-lb. With live load on left half and P_4 right, $H = 12{,}450$ lb., $M = +4200$ ft.-lb. and $V = +1020$ lb.

Practicing Engineers Suggest Lines of Progress in Engineering Education

In response to questions similar to those sent to engineering educators, whose replies were published in our issues of Jan. 2, p. 41 and Jan. 16, p. 138, the following communications from practicing engineers indicate the directions in which engineering colleges should progress in order to satisfy the demands of those who are most directly interested in the ability and capacity of the engineering graduate. Among the suggestions made are: Arrangement of technical training into three classes—trade schools, general engineering schools, and post-graduate schools; postponement of specialization; immediate establishment of an education committee; experienced teacher-specialists, especially for freshmen students; more English in the first two college years; use of moving pictures; decrease in routine examples; more thorough knowledge of materials. There is also included a short abstract from a communication received from the dean of the University of Pittsburgh too late to be included in the educators' symposium; in this two general classes of education for the future are outlined. —EDITOR.

Broad Course Without Specializing Should Precede Graduate Work

BY JOHN D. ISAACS
Consulting Engineer, Southern Pacific Company, New York

THEORETICALLY, a complete education for an engineer is a broad college course, without specializing, followed by a post-graduate course specializing in engineering. This is about the way a well-prepared lawyer is educated, and there is no reason why an engineer should not receive the same education in order to prepare him thoroughly for a profession of equal importance. If so elaborate a course cannot be followed, the student should approximate it as nearly as feasible. For example, if the best that he can possibly do is a four years' course, then two years should be strictly general and the remaining two specialized.

In case of both the engineering and the legal student, there is an important psychological objection to a long course. During the educational period as above outlined, the character of a young man should be developing, and he should be acquiring self-reliance, independence and initiative, together with that general hardening and firmness acquired only by contact and competition with other men. But during this educational period he is usually dependent upon others for his living and subject to others for the direction of his conduct and mental energies. This leaves him in a somewhat helpless condition in beginning professional life and is, in part, an explanation of the slowness with which a graduate in any of the learned professions advances in making a place and reputation.

I should like to emphasize the distinction between a specialized education and a practical one. The former is theoretical, and the teaching applies to special branches of the profession. The practical education attempts to give current, practical details, shop methods and practice; detail drawing, etc. Except in a most restricted sense I do not believe in the second of these. The time of a young man at college is too valuable to be wasted on practical details which constantly change, and if he has any time to spare it should be devoted to broadening his course, and may be well applied to a study of literature or of the classics, for example. This much should be conceded, however, that all illustrative examples should be taken from conditions occurring in practice. As a rule, a young man having a thorough, theoretical education attains in the long run a higher position than one who starts with less theoretical but more practical knowledge, although the latter is the more immediately useful. There are exceptions, of course, but these are largely due to inherent qualities.

The rapid rise of the engineer in importance and the great demand for his services have placed his profes-

sion in the same category as regards influence and financial standing as that of the other learned professions, and will more and more give engineers of the coming generations the same opportunities for complete and thorough preparation, enabling them to achieve the highest success and to acquire the wealth and honors which go therewith. While such preparation seems long and laborious, and the opportunity for achievement slow in coming, the rewards are sure and worth the struggle and waiting.

Suggests Specific Subjects for Undergraduate Course

By A. P. Davis
Director, United States Reclamation Service, Washington, D. C.

UNDERGRADUATE engineering courses should, in my opinion, include the following subjects, mentioned in the order of time to be given them: Physics, including electricity and optics; mathematics and mechanics; chemistry; history of science; geology; rhetoric, including elocution and composition of reports; hydrology; physiology, hygiene and sanitation; organization and administration; business accounting; law of contracts; specialized subjects to be elected.

Instead of differentiation, courses should be largely elective, especially in the latter years, and many specialized courses should be added to the above general list for this purpose and receive proper weight and credit. The study of modern foreign languages should take the place of dead languages in a scientific or engineering course, but no foreign language should be compulsory.

Undergraduate work should be of a general nature, to lay a foundation for growth along special lines and to train the student in original research and self-culture. Such a course should require four years above the ordinary high-school course. The highly specialized subjects should mainly be left for postgraduate work and should be strongly interspersed with practical experience in field and laboratory and in shopwork.

The greatest weakness of American education is, I believe, a lack of thoroughness. There has been much improvement in this respect, and should be more in the future. The chief aim of the entire course should be to cultivate self-reliance, logical thought, skill in weighing evidence and in tracing effects to their cause, and, above all, to arouse interest in scientific facts and scientific research. Activity is an essential condition of growth, and mental growth along right lines is the object of education. The necessary activity should be along the lines of acquiring useful knowledge and practice.

Advocates High Degree of Specialization

By Virgil G. Marani
War Service Committee on Gypsum, Washington, D. C.

UNDERGRADUATE engineering courses should include a more thorough knowledge of materials used in engineering practice and an understanding of the process of manufacture of such materials. There should be included a course of instruction upon fire prevention and fire-resisting construction and materials, and upon the causes of the nation's present excessive fire losses and waste.

Courses should be differentiated. This is an age of specializing, and this thought should be carried out during the training of the engineering mind. Coördination should only be indulged in with reference to subjects that of necessity are common to more than one course, which is not a serious problem if engineering schools are patterned after universities. Each course should constitute a highly specialized unit upon one branch of engineering study alone, and extend over a period of not less than four years' continued application, with a shorter summer recess than is customary, or the summer months should be occupied by attention to carefully planned practical application of certain theoretical studies.

The greatest weakness in modern methods of teaching is the lack of practical application, with too much time and attention given to hair-splitting theories not necessary when the graduate launches into actual practice. In many cases engineering educators have sufficient knowledge to teach, but are woefully lacking in actual, practical experience. There are many cases of educators teaching hydraulics who have never had experience in the actual installation of water-works. The same may be said for sanitation, electrical engineering and similar studies. The best instructor is the one who enters the field of engineering for a period of years, and upon his reputation and success during these years obtains a professorship and teaches the subject for which he obtained his degrees and in which he has gained later his practical experience. Many universities will promote an honor graduate to a position of instructor and finally a professorship, placing upon him the responsibility of teaching engineers, when without practical experience he is totally unfitted for such a task.

Broad General Courses Should Treat Fundamentals Thoroughly

By M. M. O'Shaughnessy
City Engineer, San Francisco, Cal.

PRESUMING the student has creditably followed the high school curriculum before entering college, I believe his first two years could be profitably spent in surveying, drawing, advanced mathematics and mechanics, physics; chemistry, theoretical and practical; geology, mineralogy, and materials of construction. The courses for all branches of the art should be identical for two years, and no specialization should be permitted until the student has opportunity to measure up his inclination and ability.

I am in favor of a broad general course for at least three years and believe better results will be obtained in this way than by following highly specialized, restricted courses. With the normal boy who has passed successfully his high-school course, say at the age of 18, I believe the college should equip him in three years with the general fundamentals. If he desires to specialize and shows great proficiency in some particular branch, he can then develop himself either in outside practice or advanced college studies, at a later date.

The greatest weakness in the engineering colleges lies in the tendency for the principals to delegate too many

of their duties to juniors. There is also seen a tendency to load the boys unduly with routine examples which often keep them busy until midnight and exhaust their vital energies. I believe the heads of departments should not keep in a state of isolation from juniors, but mingle freely with them and give them the advantage of human sympathy and interest. Very often the slow, plodding boy is discriminated against in favor of the showy and more energetic, whereas in the real test of outside experience very often the greatest advances are made by the slowest boy.

I believe the greatest headway can be made in our engineering education by teaching a number of the fundamental subjects thoroughly and not scattering useful energies wildly on too broad a horizon.

Greatest Past Weakness is Lack of Teacher-Engineers

By John S. Crandell
New York City

The average student does not know why he takes any particular course. For several years Prof. J. R. Lapham made it a practice to inquire carefully of freshmen why they had chosen civil engineering. The replies were astonishing. A large percentage replied, "Because the surveying instruments looked so nice." Many wrote, "Because father told me to." A great number, said, "Because it is such fine outdoor work." Not 5% had any well defined idea of the work of a civil engineer.

Freshmen need the most experienced and best teachers, for their minds are like twigs to be bent. Let the seniors handle the neophyte in the teaching profession; he will learn much. The freshman class should be carefully pruned; much dead wood removed, many saplings transplanted where they will do better. In fact, every college of size should have a Kathryn Blackford to sort out the human material and place it in the right files. New York University already has made a start in this direction.

Counsel from Experienced Minds

If the student does not know what he came to college for, and if his instructors make no effort to learn his natural bent, how can he be pumped full of specific knowledge? Under present arrangements we lead, push, entice, lure and haul him along a common highway until such time as he is assisted in making up his mind what he wants to do. That time usually occurs during vacation following the sophomore year. As a junior the student begins to have some aim in life. Here he needs counsel from experienced minds, from men who are as conversant with affairs outside the college walls as within, from professional "live wires"—and our colleges should be full of such men. If the student really likes engineering, let him be switched to the branch that interests him most. He may not stick to it after graduation, but that is of little moment. He will do better work in college at something he likes, and will train his mind to better advantage working over interesting problems than he will at something he dislikes.

Therefore, it is my opinion that all courses should be nearly the same through the first two years. During this time the student's mind is forming and is being formed. If nothing but English were taught during those two years the time would be profitably spent, provided the subject were properly taught. How many men are there who can write a really good business letter? How many men can write readable articles on their professional work? How many engineers can make addresses worth listening to? How many engineers have *you* ever heard give really stirring talks? Here lies the English field for engineering students; not the study of Beowulf and Chaucer, but the study of getting business with words.

Four years is long enough to fit a man to become an engineer. Highly specialized courses are for the post-graduates and the faculty members. The undergraduate has neither the inclination nor the ability to follow such work. His mind is not mature, and his social engagements prevent him giving the undivided attention necessary. Do not forget that youth will have its fling. The value of a college course is not measured by the number of logarithms a man commits to memory, but by the number of useful friends he gathers about him.

Greatest Weakness—Lack of Teachers

The greatest weakness of engineering schools is the lack of teachers. There are plenty of professors, an abundance of instructors, and multitudes of assistants. But there is, and always has been, a dearth of teachers. There are many excellent textbooks on the market, written by capable men, there are many well known names in the teaching profession, but, as Milo S. Ketchum said to me, "Too many faculty members know too little about the subjects they teach, and can't teach the little they know." The crying need is for men who can teach; men who are enthusiastic; men who are interesting as well as learned. How many of your own instructors were good teachers? Of mine I recall but three.

Teachers should be specialists. Specific knowledge should be required of them. Teachers should be selected, first, for their teaching ability, and second, for their intimate knowledge of the subject they are to teach.

But the greatest teacher of all is overlooked by every college in the land. The best and cheapest teacher, the teacher whose possibilities are unlimited, the teacher who interests, instructs, never wearies of work, and never needs a vacation, is all but ignored—the moving picture. Why have our educators failed to make the most of this truly wonderful teacher? Perhaps the extraordinarily successful experience of the Government in teaching soldiers by aid of the animated movies will awaken our college faculties. The era of teaching technical work by the moving picture is at hand. Let us grasp it *now*.

Two Types of Men Needed for Industries and Design Work

By F. L. Bishop
Dean, School of Engineering, University of Pittsburgh, Pittsburgh, Penn.

The war has emphasized the need for two different types of men in the industries and in engineering design:

First, a man who may be called a technician, who is highly trained in science and mathematics, who pos-

sesses the instinct of the research man and who can devote his entire time to highly technical research problems, either in the research laboratories which are now rapidly being developed in the large industries, or by applying the results of his research to engineering science. For the training of this type of man there is needed the best of scientific equipment, the members of the faculty must be intimately interested in research problems, and the student himself must have what is sometimes called a mathematical mind. It is doubtful that this type of man can be developed in a four-year course, under existing conditions. In fact, it is probable that such a man can be developed only in a school which has a thorough graduate department devoting its energies primarily to research, but giving instruction in the fundamentals of science and mathematics.

The second type which seems to be demanded by the industries is the man who has a broad, general knowledge of engineering subjects, and can apply that knowledge in an effective way to present engineering problems. He must have the ability to command men, a knowledge of the applications of economic principles to industries, and a broad training in the so-called humanities, since he is the man in contact with men of other types in other fields of human activities. He should not be a research man, his training in mathematics need not be of necessity so extensive as that of the research technician, but his understanding of engineering problems must be extensive.

Such a man cannot be trained in the ordinary schools, because of the artificial conditions which of necessity exist in academic institutions. He must become familiar with the industries while yet a student, in order that he may understand thoroughly the applications of his theoretical courses in school and their application to industries, and also that he may become familiar, in the formative period of life, with the problems of labor and the human factor in engineering. It is in the development of this type of man, who is to become the manager and operating head of our large manufacturing industries, that, more than in the development of any other are needed the advantages to be derived from the coöperative system, which has been adopted at the University of Pittsburgh.

Proposes Education Committee of Engineers and Educators

By J. A. L. Waddell
Consulting Engineer, Kansas City, Mo.

After many years of deep consideration, I have concluded that the best possible arrangement for future technical training is: Trade schools for the rank and file of the profession, such as draftsmen, surveyors, inspectors and the lower grades of assistants in office and field; general courses in engineering for those of higher standing; and postgraduate courses for men of superior ability, energy and ambition.

In trade schools, during two or three years of 11 months each, the pupils should be taught elementary theory and the practical things which would quickly fit them to earn a fair living in a subordinate capacity at engineering.

In the general engineering schools there should be provided broad courses, fitting the students to become useful citizens and broad-gage men, drilling them thoroughly in mathematics and the general theory of engineering, and injecting into the course only enough of higher practice to illustrate the application of the theory that is being learned. This course should cover four years of 11 months each.

In the postgraduate schools should be given thorough instruction by experts in the combined theory and practice of all the special lines of engineering. This course, for any student, should cover not less than two, and preferably not more than three, years of 12 months each.

If the Herman Schneider, or coöperative, method of teaching engineering be adopted, five years of at least 11 months each should be utilized; and afterwards, if desired, any alumnus could take one or two years of postgraduate work in some of the higher branches of engineering.

Descriptive Instruction Necessary

General descriptive instruction should be imparted concerning the salient features of engineering construction and machines of all kinds, so that the student will know what his course is driving at, and so that he may be able to read understandingly and discourse intelligently concerning professional matters. He should learn in a general way how engineering structures are put together. For instances, in bridgework he should know how the metal is fabricated in the shops, and the different methods of erecting it in the field, also how substructure work is done under various conditions. In mechanical and electrical work he should learn how steam engines function and the operation of electric motors; and he should recognize the fundamental differences between direct current and alternating current and between the motors designed for their use.

All such primary ideas concerning practical engineering should be drilled into the student early in the course —preferably in the freshman year, but certainly not later than the sophomore year. He would be interested in securing all such knowledge; for the reason that it would appeal to him because of its utilitarian nature. Many a young man has dropped his engineering course after studying for a year or two almost exclusively mathematics and other subjects of which he could not perceive the practical application to the work of earning a living.

In schools that specialize in one main branch of engineering, there should be general courses in the other main branches—given, of course, with much less attention to detail. In schools offering full instruction in all the branches, it would be ideal to let the specializing be done entirely in the postgraduate course; but, unfortunately, only a small percentage of the alumni from the geenral course can be relied upon to take up postgraduate studies, hence a certain amount of differentiation is necessary. In my opinion, it would be well to confine this to the senior year, and under no conditions should it ever precede the junior year.

After the differentiation is begun, it would not do to let the students in the different lines attend the same classes for the purely technical work. For example, the

civil-engineering students would have to receive separate, special instruction in all subjects relating to electrical and mechanical engineering, the character of the said instruction being more elementary than that provided for the electrical- and mechanical-engineering students.

Weaknesses in Engineering Education

The greatest weakness in engineering education is the failure of instructors to arouse in the students an enthusiasm for the profession and a real liking for hard mental effort. Next comes the failure to teach the students how to study and to think, how to work efficiently, how to systematize and record, and how to read, write, and speak well the English language. The neglect to instill into the young minds the ethics of engineering is also a serious and almost universal fault in technical education. Business training is provided in very few technical schools. The *elements* of business should certainly be taught in the general engineering course; and the *science* of business should be given due consideration in the postgraduate course. Nor does the subject of engineering law receive sufficient attention in technical curricula, nor the allied subject of contract writing.

Engineering economics should be begun late in the sophomore or early in the junior year and continued until graduation, more and more attention being paid to it as the student advances in essentially technical studies. It is in the postgraduate course, however, that the greatest attention should be devoted to economics; for that should be the prevailing feature in all lines of engineering investigation—and it is of investigations that postgraduate work should largely consist.

To insure the most rapid development in the engineering education of the future, there should be appointed at once, preferably by the Society for the Promotion of Engineering Education, a committee of eight, consisting of four professors of engineering and four practicing engineers, in order to study the question thoroughly and report thereon. All of these men should be adequately paid for their services; and to this end an ample appropriation of funds should be made by Congress, because the immediate improvement in technical education is a matter that is of vital national importance.

These appointees should represent the various lines of engineering; they should be chosen solely for their experience, energy and special fitness. The final report should be made as truly thorough and far-reaching as possible, regardless of expense. Urgency should be one of the prime considerations in its preparation, because the time to effect the desired improvements in technical education is *now*.

The special committee suggested should determine to what extent the Herman Schneider method of imparting engineering knowledge should be followed in the general engineering courses given in universities and special technical schools. That it is capable of splendid accomplishment has been shown beyond all doubt in the University of Cincinnati, but whether it should be adopted as the sole, standard method of teaching engineering in all the schools is a debatable point.

Some Pointers on How to Finish a Concrete Floor

Notes From a Practical Cement Finisher on Use of Screeds and Treatment of Aggregate and Surface

By William McGinnis
Cement Finisher, New York City

CONCRETE floor finishing is a trade and, like all trades, has its tricks. The difference between a good job and a bad one and between a profit to the contractor and a loss often lies in the way in which the practical finisher does his work. Some of the points which must be looked out for have been gathered here.

The setting of strips or screeds is very important. Care should be taken that they are set at a dead level and thoroughly blocked or braced underneath, so as to avoid sagging from the weight of the straight-edge during the process of screeding. In nine cases out of ten they are set in an improper or haphazard manner, through carelessness or perhaps an ulterior motive. Where this happens, sagging is inevitable. The floor as finished is not level and depressions are formed, for the time perhaps not visible to a casual glance but later appearing with attendant costs. For instance, during the first troweling the pressure of the float or trowel brings some water to the surface, which afterwards finds its way and trickles into the depressions, forming pools. By the time that these pools are very noticeable the finishers will have worked several yards away, and it would cause too much trouble or annoyance to remedy the defect, so it is passed over. Now, it takes hours in most cases—sometimes from six to ten hours, depending on the depth of the slab—before the water in those pools or pockets is thoroughly absorbed in the aggregate, and the result is that the finishers are obliged to "wait" before they can properly finish the floor, and, even then, they must work slowly over the depressions to avoid leaving "trowel marks," owing to the uneven surface.

Disadvantage of Using "Dryer"

Of course, the pools can be dried by an application of "dryer"—that is, a dry mixture of cement and sand or gravel, poured or laid in the depressions, to absorb the water. This is very often done, but necessitates walking over the fresh concrete, thereby causing other holes and disfigurements, which only retard the finishing, though the cost will be somewhat less than it would be if the finisher waits for the pools to dry out. In both cases overtime charges are common.

Where strips or screeds are properly set and are rigid, no depressions or pockets are left in the surface, and consequently the water in the aggregate is more evenly distributed, thus causing a uniform set. The finisher's trowel glides easily over the surface, "waiting" and extra work are eliminated, and the result is a great saving of time and money. Strips or screeds spaced about 12 ft. apart give the best results. The straight-edge should be about 15 ft. in length, thus allowing an overlap at each end, and should be of a strong, rigid, light wood of 2-in. thickness, for on heavy screeding or "pulling" it often becomes tilted,

and, if less than 2 in., will sag or bend from the strain of pulling, leaving the surface in a more or less rolling condition, which necessitates a second screeding and a consequent loss of time.

In "raw" finishing—that is, one-course work—the proper setting of screeds is, if anything, more important, as the screeding or leveling is heavy and laborious, depending on the aggregate. For instance, crushed rock 1½ in. or less in diameter, with its attendant mixture of sand, etc., can be screeded faster and more easily than rock or other material of a larger size. In finishing a floor of this nature, it is usual and necessary to scatter or apply a layer of dryer over the whole floor to assure a "working surface," and this is usually done when the finishers are about to proceed with the first troweling. This necessitates walking or laying boards over the fresh concrete in order to apply the dryer, causing depressions or holes in the surface. This is the wrong way; the dryer should be mixed beforehand, and, as the screeding progresses, it should be immediately applied evenly to a depth of about ¼ in. In this way it acts threefold: (1) It begins at once to absorb the water on the surface; (2) it eliminates subsequent walking over the fresh concrete, and (3) it saves time.

How to Treat Slag Aggregate

In "raw" finishing where slag is substituted for crushed rock or otherwise, it will result in a great saving of time if the slag is wet and thoroughly soaked for several hours before being mixed in the aggregate. It is a light material, and some particles are lighter than others, though of the same size. When the slag aggregate concrete is poured and screeded, if the slag is not wet down the lighter particles will persist in coming to the surface, where they will remain in spite of all efforts to submerge them, and the finishing becomes very tedious. When the finisher is floating and troweling, those particles have the same effect as trying to float marbles into a hard floor; they roll with the floating, scratching the surface, and very often have to be picked out by hand and cast aside. Again, the edges of the finishers' trowels are nicked and torn, and have to be filed or ground down, and considerable time is lost in the process. In trying to overcome all this, an extra heavy layer of dryer is required, although its success varies, in some cases requiring a second layer, thus consuming extra material and the time in mixing and laying it on the surface. Where slag is thoroughly wet and soaked before being placed in the aggregate, it absorbs a certain amount of water, thus gaining added weight, and is not so apt to appear on the surface, so it requires less dryer and less time in the process of finishing.

On floors previously left unfinished and which later require a top coat of cement mortar or wearing surface, either an acid or a cement wash is used, to assure the adherence of the mortar. Acid should be applied freely at least one hour in advance of the finish concrete pouring, but afterwards, and slightly in advance of this finish placing, the surface should be swept lightly to prevent an excess of water in the mortar. Cement wash should be applied only barely in advance. In pouring, the mortar should not be dumped or heaped at random about the floor, as usually happens, for in case of any excess of water this sets up a dam and creates "soft spots" which retard the finishing. It should be poured in a continuous mass, of an even consistency, somewhat in the nature of a thick paste, and raked always in the one direction. In this way "soft spots" are avoided and a uniform set is assured throughout.

In floors where squares are required, considerable time is occupied in the jointing operation. The smaller the squares the more joints are required, and the more time is consumed. In marking out or spacing joints the ordinary way is to measure out and make notches around the edge of the floor, after the first troweling. This is wrong, as it necessitates walking over the fresh material, and is a slow process. The economical way is to mark out chalk-marks on the walls or outside of the forms, before the material is poured, thus saving time and extra work.

The high cost of finishing cement or concrete floors can in many cases be attributed to negligence, or to a lack of knowledge on the part of those charged with responsibility. Every defect adds to the cost, and the right way is the economical way. To the causes shown in the foregoing others might be added, but all can be summed up in the words, "Faulty supervision."

Macadam Road Built by Red Cross Refugees in China

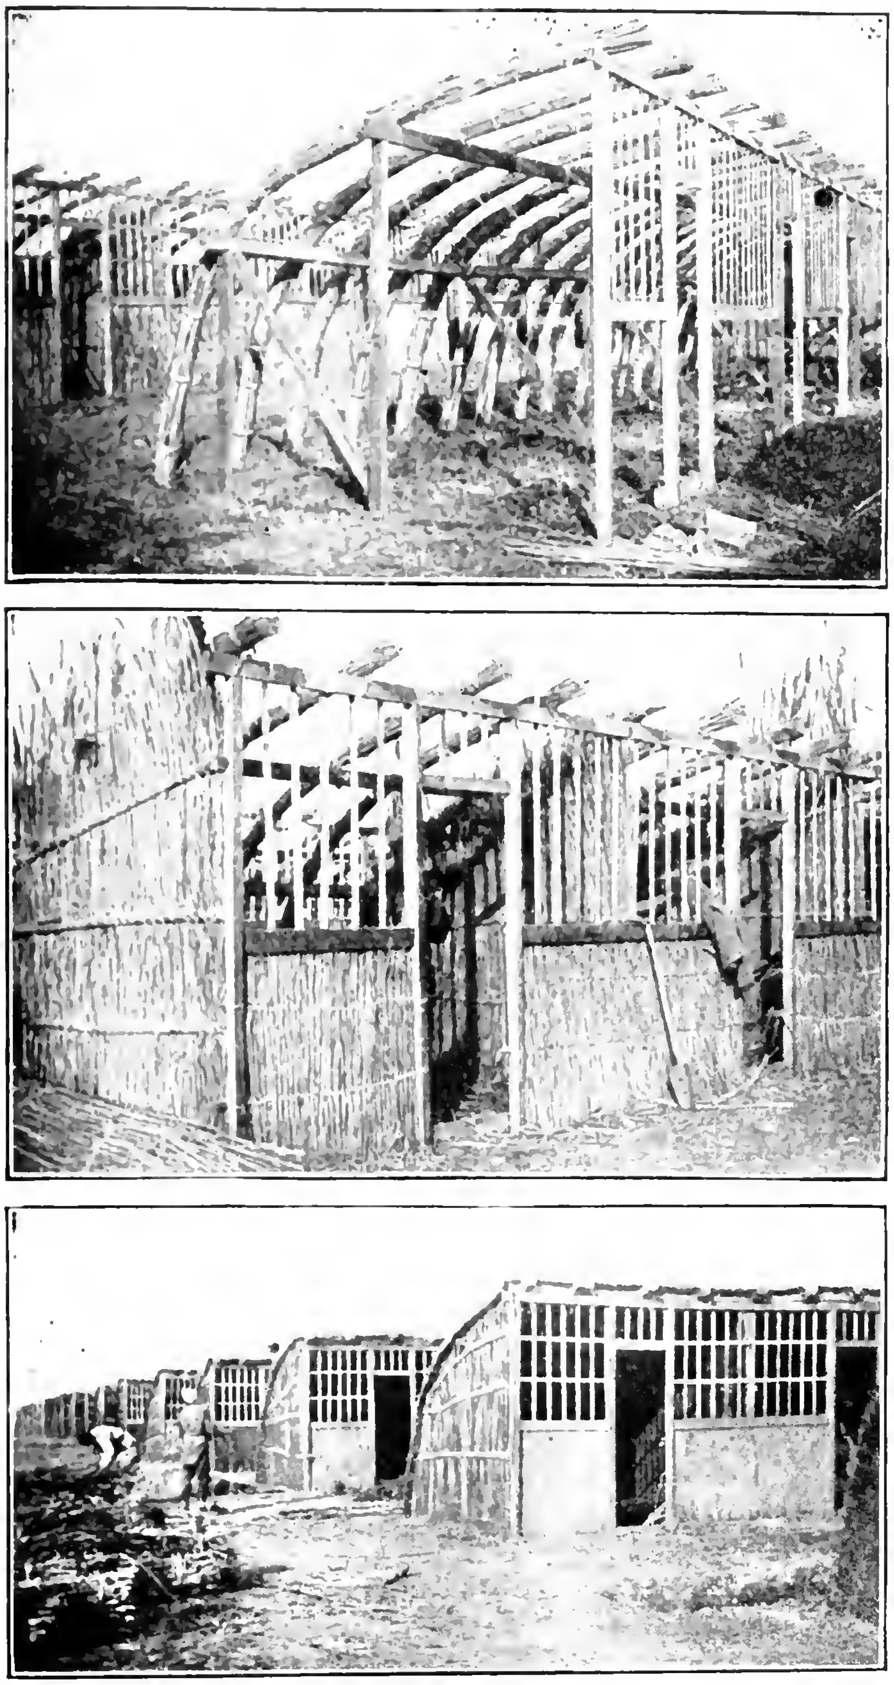
Granite Slabs of Old Road Used for Edging—Type of Camp Built—Macadam Stone Broken by Hand

By R. A. White
Peking, China

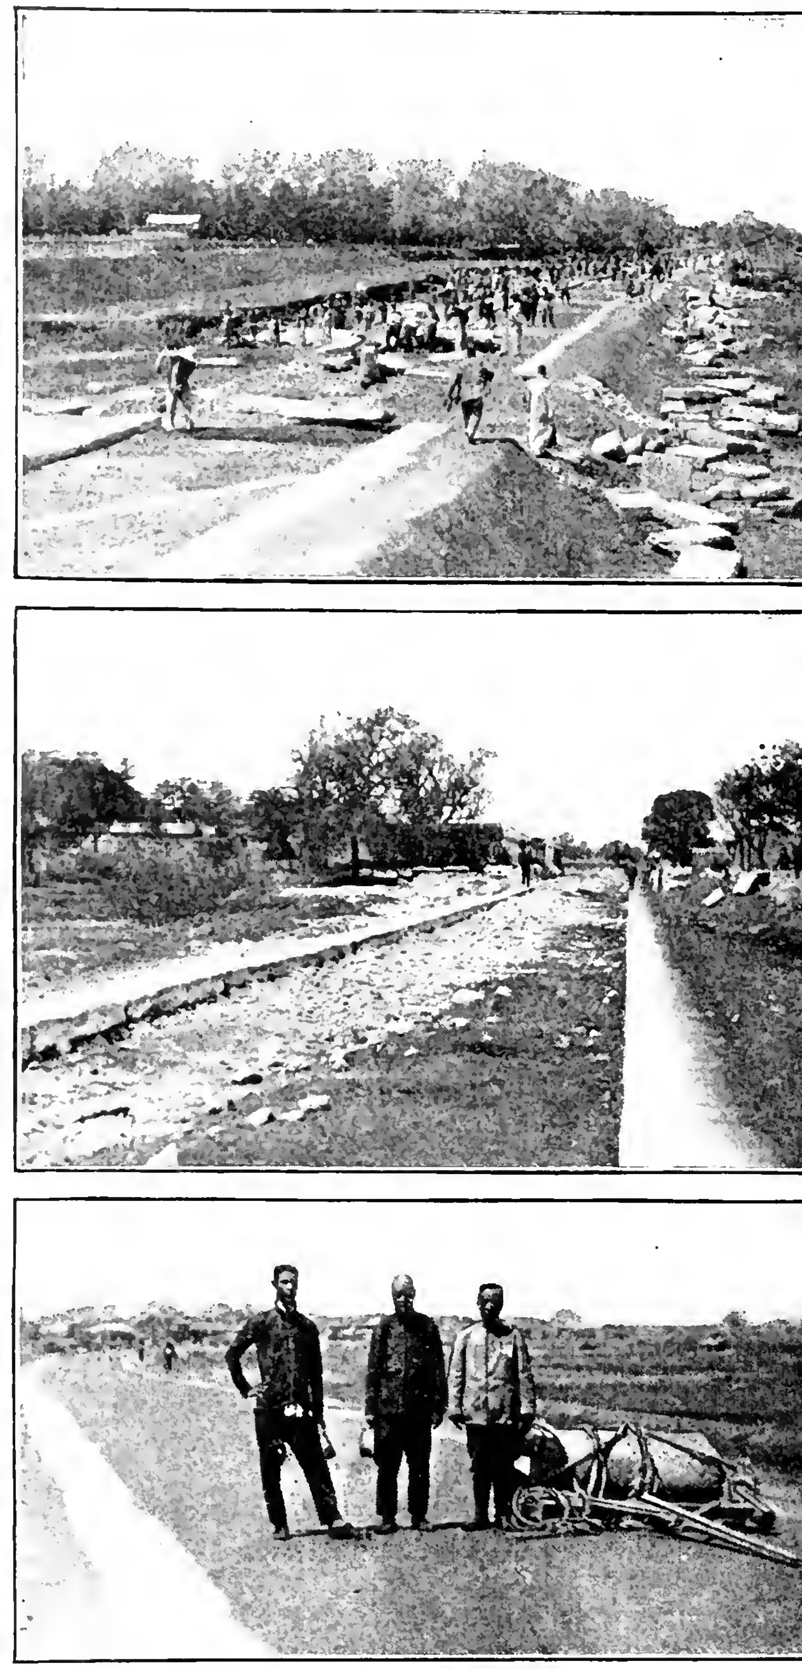
Construction of a modern macadam road to replace a worn granite-slab road has been effected in China by the use of Red Cross refugees. The old roadbed and materials were utilized as far as possible, and edgings 2½ ft. wide were built on each side, by the use of the old slabs which formed the existing surface. Metal for the new surfacing was produced by breaking the remainder of the old surface by hand sledging. Thousands of refugees were housed and fed in specially built camps by the Red Cross.

Late summer and autumn rains in 1917 caused the rivers of Chili Province in northern China to overflow their banks so that many thousands of square miles of rich farming country were flooded, and hundreds of thousands were made homeless. In some cases the water stood several feet deep, entirely destroying the 1917 crops, and when winter came the water had not yet subsided. To save the people, the American Red Cross of Peking, headed by the American minister, appealed to the Red Cross officials in America and received $50,000 in gold, with which a camp was built at Tientsin. This camp, which would house 5000 refugees, was built and filled with occupants in one month. The method of construction of these camps of Oregon pine framing and reeds covered with plaster is shown in the accompanying illustrations. Each one-room house, 9 x 10 ft., accommodated five persons.

Early in November, as the cold weather came on, it was evident that more help must be given. It was



CONSTRUCTION OF REFUGEE CAMPS IN CHINA



RECONSTRUCTION OF OLD SLAB ROAD IN CHINA

not thought advisable to build more camps, but rather to undertake some construction work, which would both benefit the refugees as well as be of some permanent value to the country. Accordingly, the American minister, Dr. Paul Reinsch, sent a second call for help to the American Red Cross, and this, combined with $100,000 paid over by the Chinese Government, made a fund of $200,000 which was set aside for construction work.

Considerable time was lost in deciding which kind of work to take up, but finally the writer, with George A. Kyle, chief engineer of the American railway projects in China, was asked to make a reconnaissance survey and estimate of a highway between Peking and Tientsin. It was found that the entire project, which practically followed the course of the allied march to Peking in 1900, would cost more than $500,000. It was, therefore, decided to construct immediately the section between Peking and Tungchow, a distance of 14 miles, which would afford work for 3500 refugees. These were soon recruited by local missionaries from the flooded areas adjoining Paotingsu. The men were a sorry sight upon arrival in Peking, for they had gone for weeks with little or no food and had very little clothing. It took several weeks to get them in shape for work.

Plans for the project were prepared by Mr. Kyle and the writer. Much thought and attention had to be given the viewpoint and stand taken by the Chinese officials that highways are the natural competitors of the railways. Due to this theory, one finds in China two cities of over 1,000,000 inhabitants, Tientsin and Peking, only 82 miles apart, and with only one single-track railway and an unused canal, long since fallen into decay, connecting them. Inasmuch as a through highway would be a natural competitor of the railway, according to the Chinese view, no highways connect the capital of China and the thriving port of Tientsin.

Tungchow, to which point produce comes by sea, river and canal from the entire country, had been connected with Peking by a granite-slab highway built

originally by the Ming emperors in the fifteenth century for transporting tribute grain overland. The highway was reconstructed during the 26th year of Chien Lung's reign, about the year 1750. Inscriptions on marble slabs placed on tortoise backs along the roadside describe how some 240,000 oz. of gold had been spent to benefit the country people in the neighborhood, in the building of this highway. It was 21 ft. wide with a curbstone set on each side, while the granite slabs were placed across the road and well embedded in a lime-concrete foundation, varying from 12 to 18 in. in thickness. The road was on a fill averaging 4 ft. high. The slabs were about 1 ft. thick, 2½ ft. wide, and varied in length from 4 to 15 ft. Continuous use of the road for centuries had worn ruts to such an extent that the road was practically useless for traffic.

Various stages in the construction of the new road are shown in the accompanying illustrations. The macadam section is 15 ft. wide, with slabs of granite on each side 2½ ft. wide to form an edging. The shoulders are of earth 4 ft. wide with 1 on 1½ slopes. In laying the slab-edging, the stones were set into the old lime foundations about 6 in., so as to avoid filling in with earth under the macadam, which was about 6 in. thick. The roller used to compact the macadam, the method of transporting in baskets supported on a pole carried by two men, and the stone-breaking yards along the highway, may be seen in the illustrations.

Refugees working on the roads were allowed a minimum monthly wage of $6.50 Mexican money, or about $5 in gold. Their food costs about $2.70 per month, and, after deducting this amount from the allowance, the balance is sent to the workman's family. Work was done on a piece-work basis, whereby they were paid an additional amount if the work done exceeded the minimum wage. The following prices, Mexican money, were paid:

Breaking ballast, per cubic foot	$0.04
Earth work, including ramming, per cubic foot	.04
Removing granite slab, per square foot	.02

It is purposed to have carts use the shoulder and granite edging, and as ruts are formed broken stone will be filled in. Metalled highways are not built, according to the official viewpoint, for the Chinese farmer or teamster, but for the nobility, who use rubber-tired vehicles. The carts mentioned have two wheels about 4 ft. in diameter with rims only about 1 in. wide and often carry as many as 20 pigs, the load weighing from 1½ to 2 tons. This type of wheel is ruinous to macadam roads, which will never be a success until the use of wide tires for the carts is made compulsory by regulation.

What the Government Did in Inland Waterway Navigation

Director General of Railroads Reports on Progress Made During 1918 on Waterways Taken Over By His Administration

GOVERNMENT control of inland waterway navigation was undertaken for the first time in 1918 by the United States Railroad Administration. Little actual progress was made by the end of the year, but such foundations for future work as were laid were outlined in the annual report of the retiring Director General of Railroads, W. G. McAdoo. That report, with the exception of the section relating to the New York State canals, which was presented in *Engineering News-Record* of Feb. 20, 1919, p. 370 is abstracted below:

Hundreds of millions of dollars have been expended by the nation, the states, and citizens for the purpose of developing our inland waterways and for the construction of canals. Thousands of miles of rivers, canals, lakes and bays are ready to assist in moving our products. These waterways, with the exception of the Great Lakes, are not being extensively used.

With the assumption of my present task, I appointed a committee to make a prompt investigation and to suggest a definite plan for the additional use of internal waterways, for the economical and expeditious movement of the traffic of the country, so as to relieve or supplement the railways under the conditions caused by the war. This was the beginning of a program which had been constantly pursued, and while the greater urgency for raw materials in war work interfered with the construction of steamers and barges, 160 steel, wood and concrete vessels are now building and 50 steel and wooden craft have been purchased. The total appropriation for old and new floating equipment exceeds $11,750,000.

The increased responsibilities of this country in the family of nations will demand greater commercial activity on our part. Transportation is a major problem, for, on account of the extensive area of our country, we have a longer average haul to seaboard than other industrial commonwealths. It has seemed to me evident that by developing transportation on the waterways and coördinating and articulating them with a unified railway system, we shall bring about a correct solution of the rail-water controversy, which has been in progress for 50 years. This is possible with the railways under Federal control. I doubt if any of our rivers or canals will become active factors in transportation if the railroads are turned back to private control. The old methods of railway competition with the waterways doubtless will be revived, and the waterway experiment may not be able to survive that competition.

Mississippi-Warrior Waterways

On July 11 there were created the Mississippi and Warrior Waterways, and M. J. Sanders was appointed Federal manager to have charge of the construction and acquisition of equipment for use upon the Mississippi River between St. Louis and New Orleans, and for use upon the Warrior River between the Alabama coal fields and Mobile, and in connection therewith for use upon the Mississippi Sound and connecting waters between Mobile and New Orleans, and to operate such equipment upon these waters in the Director General's behalf.

To establish immediately a water service on the lower Mississippi River was a matter of some difficulty, on account of the scarcity of suitable equipment. It was finally determined to purchase the fleet of the Kansas City-Missouri River Navigation Co., consisting of two towboats and nine barges, which, previous to the present season, was operated between Kansas City and St. Louis, Mo. The sum paid for this fleet was $458,500. No other suitable barges were available, with the exception of 20 steel barges in the St. Louis district, United States Engineers, that were used in revetment work and dredging. An arrangement was made whereby these barges were obtained under lease from the Engineer Department until June 1, 1919, together with two steel towboats. A third towboat was chartered from a civilian. There are now in service between St. Louis and New Orleans five towboats and 29 barges, the first sailing occurring from St. Louis Sept. 28. A weekly service is now being performed. Necessarily, there has been con-

siderable delay in the creation of joint tariffs and joint rates with the railroads, so that the operation has been restricted to such traffic as originates on the rivver banks, and also, because of war conditions, considerable decrease in north-bound business has resulted on account of the zoning of sugar. South-bound tonnage is largely composed of wheat and other cereals. The operation to the latter part of November, comprising five round trips, shows a total revenue of $48,500 and a total operating expense of $52,000, exclusive of overhead.

Authority has been issued for the filing of tariffs covering joint through rates between New Orleans and adjacent points taking the same rates, and points in northern Missouri, Illinois, Iowa, Wisconsin and Minnesota in both directions. These tariffs are now being prepared and will shortly be filed. The through rates reflect the differential of 20% between the rail rates and the water rates between New Orleans and St. Louis.

A terminal of considerable capacity is being erected in the City of St. Louis, and the terminal in East St. Louis has been purchased from the Kansas City-Missouri River Navigation Co. Arrangements for the use of ample terminals are being negotiated with the City of New Orleans.

The Director General has just authorized the construction of six large steel towboats and 40 steel barges (capacity 2000 tons each) at an expenditure of $6,170,000 for service on this waterway; estimated annual capacity, 850,000 tons. Operation on the Warrior River previous to this year has been irregular. Since the creation of the Missippi-Warrior Waterways Section the administration has purchased three towboats, 21 wooden barges, and six steel self-propelled barges for service between Cordova (near Birmingham, Ala.) and Mobile, Ala., and New Orleans, La. The cost of this equipment, after reconstruction and necessary repairs are completed, will be about $700,000. These vessels are primarily coal carriers and the annual capacity is estimated to be 300,000 tons. A portion of this fleet is now in operation.

Sufficient coal is produced from mines on the river bank in the Cordova district to employ the fleet constantly. The Director General has just authorized the construction for this service of four steamers to trade between the Birmingham district on the Warrior River and Mobile, Ala., and New Orleans, La., these ships to be designed to carry merchandise as well as coal—the total cost will be about $1,000,000; also, that three steel towboats and 20 wooden barges be constructed for coal service on the Warrior River. The cost of this equipment is estimated at $600,000; estimated annual capacity, 375,000 tons.

Delaware and Raritan Canal

This waterway, extending from Bordentown, N. J., to Raritan Bay, New York Harbor, being of limited draft and inadequate lock structures, had suffered a steady decrease in business up to 1918. It was taken under Federal control as a part of the transportation system of the Pennsylvania Railroad Co., to which it has been leased for many years past. Last year 272,734 tons were moved. It became evident early this season that there would be a very marked loss in tonnage due to the fact that coal was being shipped via other routes. In July the Division of Inland Waterways took charge of the floating power equipment on the canal and of the toll collections, and Dec. 1 the operation and maintenance of the canal was transferred to this division. The increase of tonnage over last year will be about 5%. The gain in the transportation of merchandise and high-class freight has more than offset the shortage of the movement of coal. The Railroad Administration has operated from three to 15 craft between Philadelphia and New York. The season is not completed, but it is apparent the ships, which were in all cases leased, will show a very small deficit, even after charging 10% of the expense of maintaining the New York office of the New York and New Jersey Canal Section to this service.

Chesapeake and Ohio Canal

This canal has been operated at a loss for several years. With the opening of navigation season of 1918 it developed that the Canal Towage Co., which operates the boats of the canal, was not attempting to engage in business. The traffic is almost confined to the transportation of coal, and, as the canal served particularly the needs of Washington and vicinity, the Railroad Administration regarded it important to preserve this utility, and entered into an arrangement to pay the toll charges on the boats of the Canal Towage Co. or any other coal boats. No other boats having appeared, this arrangement was later changed, and a new agreement entered into whereby the Railroad Administration guaranteed the towage company against any operating deficit. There was also authorized the construction of 10 barges to be used on this canal.

The tonnage moved in 1918 will be slightly less than the quantity moved in 1917, but the quantity moved to Washington and vicinity greater. There are two reasons for this: (a) A late opening and scarcity of boatmen, and (b) greater mileage per unit, resulting from the larger percentage of coal delivered to Washington and Indian Head. Although the accounting for the season's operation is not completed, it is apparent the operating deficit will be much less than the toll charges.

Intercoastal Waterway

An investigation was made of transportation conditions on that portion of the inland waterways between Philadelphia and Beaufort. This inquiry shows there is sufficient vessel equipment for normal seasons, and that the various barge companies have been and are building new equipment. There has been a lack of coördination between shipper and vessel owner. A number of vessels ordinarily used in this service has been under charter to the various military and Navy branches of the Government. These are being released to the owners.

The methods of handling freight on this waterway are out of date, and as the supply of labor promises to be somewhat improved, the efficiency of the present fleet, with modern terminal methods, should be increased 30 per cent.

In view of the fact that the projected locks and dams on the Ohio River between Pittsburgh and Cairo are not completed (the improvement has not been finished between Pittsburgh and Cincinnati) it does not seem a proper time to consider any new equipment for this route.

Broad City Planning Program for Pittsburgh

The newly organized Citizens' Committee on City Plan for Pittsburgh, of which C. D. Armstrong is president, has the following as its general program:

Conformity to definite plan of orderly development into which each improvement will fit as it is needed—not the immediate execution of the whole plan.

Saving in cost of public improvements by business methods—not waste through unnecessary or extravagant expenditures.

Encouragement of commerce and facilitation of business—not the obstruction of any trade activity.

The development of an American city worthy of civic pride—not an imitation of London, Vienna or Paris.

Conservation of human energy and preservation of life, particularly child life—not merely restrictive, but also constructive welfare methods.

Correlation of the city's activities—not haphazard changes with no adequate returns.

The proper application of art to municipal improvements—not extravagance, superficial beautification or vague attempts at civic adornment.

The rule of common foresight and prudence—not the rule of chance with ruinous expense and debt.

Preservation of historic buildings with their traditions—not the destruction of the old landmarks and city individuality.

Happiness, convenience, health, for all citizens—not merely expensive boulevards and parks for the few.

A Section Dealing with the Results of Teamwork by Technical Men

St. Louis Engineers to Engage Actively in Civic Affairs

The Associated Engineering Societies of St. Louis. with a membership of about 775, of whom 575 are in the Engineers' Club proper and the remainder in the local chapters of various national societies, are becoming active in civic affairs. At a meeting of the Engineers' Club Jan. 8 the following resolution was announced and passed:

"Resolved, that the Engineers' Club of St. Louis adopt the principle of taking a more active interest in economic, industrial and civic affairs."

At this meeting, also, the civic committee of the club was instructed to report on the need of a new state constitution for Missouri, on the possibility of issuance of state bonds for highway construction, and on the proposed issue of municipal bonds for public improvements in the City of St. Louis. In furtherance of the investigation and in view of the possibilities of state road construction, the club sent one of its members to the state capitol to attend the public hearing before the legislature.

Business Methods Put Speed into Road Association Work

Such marked success in handling a large amount of work was attained in a conference on rural concrete roads held Feb. 10-11 by the Mississippi Valley Association of State Highway Departments that the procedure is given below. For the discussion of various points the subjects were divided into 12 groups, each assigned to a committee, as follows: Grades and drainage; grades and pavements on culverts; widths of pavement and shoulder treatment for single- and double-track roads and state trunk lines; thickness and crown of pavement; alignment; widening and superelevation of curves; aggregates and proportioning; joints; reinforcement; handling materials from point of production to the work and into the mixer; preparation of subgrade and side forms; water supply; consistency; placing, finishing and curing in warm and cold weather respectively; testing of materials; field and laboratory inspection.

Six delegates were invited from each state, three from the State Highway Departments, and three engineers outside, also district engineers of the United States Bureau of Public Roads. Engineers of the Portland Cement Association attended at the invitation of the chairman, A. R. Hirst. Each delegate was assigned to serve on two committees. The first six committees met separately on the first morning of the conference and formulated their reports. As a basis for these reports there was in the hands of each member of the committee the recommended practice for concrete-road construction by the Committee on Concrete Roads and Pavements of the American Concrete Institute.

In the afternoon these committee reports were presented to the conference and there passed upon. The following day the remaining six committees handled in a similar manner the subjects assigned to them. The result was a large amount of work accomplished in a minimum space of time.

One of the chief objects to be accomplished was to agree as far as practicable upon the general practice for the construction of concrete roads in the Mississippi Valley states and to decide as to what this practice should be on points which were necessarily left open by the committee of the American Concrete Institute. So successful was this method of handling the meeting that it was the general sentiment that the future meetings of the Mississippi Valley Association would probably be arranged in a similar manner.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Educational Training for Minor Engineering Positions

Sir—The recent correspondence in your columns relating to the education and compensation of civil engineers dwells on the subject mainly from the engineer's viewpoint. The viewpoint of the employer is equally important, for he holds the purse strings, determines the compensation and thereby fixes the standard which ought to be the basis for determining the expenditure of time and money it is wise to ask parents to approve as right for technical education. It is manifest folly to overeducate a man for his duties, unless the excess education calls for no parental sacrifice and fits the youth for a broader life.

The employer wishes to pay a fair market price for the engineer's work, but he sees no valid argument for paying more than that. He expects the price to be based on the quality of the technical knowledge required and the time consumed in performing the work. This is the basis of his payments for painting, for instance, for he expects to pay one price for whitewashing his cellar, another price for painting his house, another price for decorating the ceiling and walls of his parlors, and still another price for the preservation in oil and pigments, for the benefit of posterity, of those facial lineaments in which he takes a pride, more or less concealed. He knows what he should pay for such services.

But when, on the very few occasions he needs the help of a civil engineer, and he is without any measure by which to determine the fairness of the bills rendered to him, he notices that the work is actually done by men who are manifestly not paid highly by the engineers employing them. It is inevitable that he should endeavor to pay for such work about on the basis of house painting, for he cannot see that it calls for any greater skill, training or judgment.

In all the discussions of engineering education and compensation the point is overlooked that the requirements for the actual performance of the work to be done form the only basis on which arguments should rest. If the work is promptly, economically and well done, its actual value is not affected by the fact that the man who does it is an authority on municipal government, or able to read the New Testament in the original Greek or, on the other hand, is without training to do anything requiring greater skill and has no education to speak of. The employer is justified by every principle of economics in paying for that work only the minimum price necessary to have it done properly. If he wishes the work done by an expensive specialist who actually delegates it to a low-salaried employee, he has the right to have it done so, just as the great specialist has the right to charge only what the work is actually worth and not what he could earn by turning his attention to more difficult tasks. That men sometimes knowingly pay more than work is worth and charge less than they can earn at the most lucrative classes of work should not becloud the fact that the minimum price at which one class of work can be obtained regularly is the actual measure of value of that work.

Neither the education nor the compensation of civil engineers will be placed on a logical basis until the actual nature of the work done in civil engineering is dissected into its component parts, and the education and training actually required to perform each of these parts are conclusively determined. This means, not the superficial knowledge of history, languages, assorted sciences, literature, economics and the like, "without which no young man is fitted to take a responsible place in his profession," but the knowledge and skill actually needed to do that thing well. When such an analysis is made, it may be found that a very large part of the work done by engineers is really little more than skilled labor. Some of it may be highly skilled labor and deserve corresponding compensation, while part of it may call for no great skill and none of that ability in the direction of men and the reduction of costs which always has been and always will be highly paid because it is executive in nature.

It is debatable, to say the least, whether the present educational training for the engineer is not a questionable thing for the average young man to attempt, provided his circumstances are such that the time and money required for a complete course entail a serious sacrifice by his parents, brothers and sisters. If no such sacrifice is involved, such an education is an admirable thing; if the lad is certain to become a leader, the education is equally desirable; but how many of the thousands of technical-school graduates, educated at the expense of the greatest self-denial of their families, are earning today any more money or living any fuller and happier lives than would be the case had they gone to good trade schools and saved the years of study and hundreds of dollars spent in getting through a technical college?

One of the fundamental difficulties in this closely knit matter of engineering education and compensation lies in the common, wholly erroneous assumption that four years of technical school training superimposed on top of four years in a high school are necessary to train the average youth to perform the average work done in an engineering office. Every engineer in charge of a large office knows it is not true. Yet the young man who has been urged thus to spend these years of preparation has been assured that he must do it in order to carry on this average work, and his investment of time and money deserves a compensation commensurate with such a long educational training rather than the compensation he actually will get, based on the time really needed to acquire the requisite skill and knowledge in other places than a technical college.

Four years in a good trade school, run solely to give the training really needed under men inspired with an enthusiasm for teaching rather than a yearning for research, may be found just as helpful to the great class of young men who are perforce economical of both time and money. These men would go out to their engineering jobs without any of the feeling held by young graduates of technical schools that surveying, drafting, supervision of construction and the like very useful classes of work which do not call for special knowledge or executive ability deserve compensation at rates beyond those paid for similar attainments in other professions or callings.

In closing, attention is called to the very large class of technically trained men who leave engineering for contracting, manufacturing or commercial work. It is open to question if the eight years spent in high school and technical college have been a good investment for them. It is noticeable that they are generally young men with small means upon graduation, whose education has been a strain upon their families. The salary question is particularly serious to them. They have discovered that the greatest opportunities for capitalizing whatever technical knowledge they have acquired are in the competitive strife of energetic man-to-man endeavor rather than in the seclusion of a drafting office or the trackless wastes traversed by a surveying party. It is only this class which shows an inclination to speak disparagingly of present engineering education as the best system for all prospective engineers, but it should be noted that it is only this class which is not complaining about poor pay and lack of public recognition.

Upper Montclair, N. J. JOHN M. GOODELL.

Railway Bridge Impact Experiments Seventy Years Ago

Sir—Mr. Waddell's valuable contribution to the literature of impact on bridges in your issue of Nov. 21, 1918, p. 924, appears to me to give insufficient credit for the work done by the royal commission on iron bridges in 1849, and, as the work of this commission is almost invariably misquoted, I trust I may be pardoned for briefly stating the results.

The first experimental work of the commission was carried out at Portsmouth by James & Galton on cast-iron bars 9 ft. long, which were tested to destruction. Professor Willis enunciated the analytical problem and Sir G. G. Stokes obtained an approximate solution without periodic terms. He showed that his solution was equivalent to calculating the centrifugal force of the load. The impact effect in the Portsmouth experiments was found to be very great, and Willis showed that the experiments did not represent dynamical models of

actual bridges. The Portsmouth experiments did not, however, verify Stokes' analytical results, and the discrepancy was shown by Willis to be due to the fact that Stokes had neglected the periodic terms in his solution; in other words, the passage of a load sets up a vibration, and this vibration had been neglected in the analysis. Stokes then calculated the amplitude of the vibration and his results were then verified by Willis in a series of delicate laboratory experiments at Cambridge, using an ingeniously constructed dynamical model. Professor Willis shows in his summary of the investigation that in actual bridges it is only the periodic terms of the solution (the vibration of the bridge) that are of importance. The whole of this investigation neglected the effect of the periodicity of the load due to unbalanced masses.

The analytical work of Milan in 1893, referred to by Mr. Waddell, was principally the calculation of the centrifugal force of the load; i.e., the nonperiodic part of Stokes' solution. C. W. LLOYD JONES,
Superintendent of Way & Works, His Highness the Nizam's Guaranteed State Railways Co., Limited.
Secunderabad, Deccan, India.

State-Insured Highway Construction Contracts Suggested

Sir—In your issue of Jan. 30, p. 257, there appeared under the title, "State-Insured Highway Construction Contracts Suggested," an article which states that it has been the custom of surety companies to provide contractors on state work with certified checks to submit with their bid. This erroneous statement is based upon the actions of a certain few political insurance brokers, who thought that by providing these checks they would corral all the insurance business, and also place the contractors under heavy obligations to them in other ways. It never was the custom of the surety companies to provide contractors with certified checks for bid purposes.

The article also states that large amounts of money have been paid to surety companies by contractors on state work, and that the companies have lost but little money on the payment of losses. The fact is that the surety companies have paid the state hundreds of thousands of dollars to cover losses. Some underwriters assert that the losses paid exceed the amount of the premiums received.

Many persons, engineers, architects and state officials, do not realize just what the contract bond is. They seem to think that a bond is like a policy of insurance, to cover all kinds of losses, which can be obtained by merely walking into the underwriter's office, laying down the premium and walking out with the bond. Instead, a bond is a three-party contract between the contractor, called the principal, the owner or the state, called the obligee, and the surety; and certain very definite obligations are placed upon each party and certain very definite rights given to each party.

The contract bond is a guarantee on the part of the principal that he will fulfill his part of the contract, and this contract is backed up by the surety company which is organized and operated under the banking and insurance laws. When there is a difference of opinion and a dispute between the principal and the obligee as to facts, the surety or bonding company can make payment on the bond to the obligee only after the dispute is adjusted, and it is determined that the obligee is entitled to recover. The high-grade surety companies have never refused to pay such losses. The surety bond is designated to protect the owner against a loss which he might suffer due to the unexpected and unforeseen contingencies that may (and frequently do) arise to cause even the financially strong contractor to default on his contract.

The hazard in writing surety bonds is so great, and the losses have been so big, that of 10 surety companies which were in businesss 10 years ago only four are now doing business. The others have either been forced to the wall or compelled to merge with stronger companies, by reason of the severe losses sustained on contract bonds. Road building, especially, has proved so hazardous that a contractor today, in order to obtain a bond on a road contract, must prove himself financially stronger and better equipped to perform the work than would be required for almost any other class of work.

There is little likelihood that the legislature would be induced to allow the state to embark on such a hazardous undertaking as the underwriting of contract bonds. HARMON V. SWART.

New York, N. Y.

[Mr. Swart's letter was submitted to the New York Commission of Highways, and Mr. Morris, the secretary, replied as follows:—EDITOR.]

Sir—Your letter of Feb. 20, inclosing a letter from H. V. Swart dated Feb. 18, is at hand

The fact that highway contractors were provided with bidding checks cannot well be denied, in view of the volume and extent of the transactions; the openness with which they were carried on; the number of years the practice existed, and the knowledge generally possessed by all persons connected with the work in regard thereto. No claim has been made, however, that all participated in this practice.

I note that Mr. Swart says that surety companies have paid hundreds of thousands of dollars to the state on losses. I have no knowledge as to what payments have been made with regard to work other than highway improvement; the report of this department referred only to that class of work. As to highway improvement losses, however, it is a fact that from 1898 up to 1917 the records show that total payments by all surety companies for losses on forfeited contracts did not exceed $15,000; the premiums paid during that period for highway improvement work are understood to be something over $500,000.

Mr. Swart states that road building has proven so hazardous that the contractor to obtain a bond on that work must be financially stronger and better equipped than would be the case for almost any other class of work.

The insignificant amount paid during the period above mentioned is of itself an indication as to the lack of hazard. Highway improvement work is free from danger of fire, and, except in very unusual cases,

and even then to a limited extent, is free from any danger of flood. The work lies on the surface and there are none of the dangers of quicksand, cave-in and like hazards which are encountered in many other classes of public works. In short, where road contractors use due diligence in preparing their proposals and obtain contracts for reasonable prices, the danger of loss, under ordinary conditions, is reduced to a minimum.

I. J. MORRIS,
Secretary, New York State Commission of Highways.
Albany, N. Y.

Right-Hand Door Has Clockwise Swing

Sir—In answer to H. L. Conrad's query in your issue of Jan. 23, 1919, p. 201, regarding the swing of doors, I wish to say that one sure way of determining a right- from a left-hand door is as follows: Consider the hinge as the center of a clock; if the swing is in the same direction as the pointers then the door is right-hand, if opposite then it is left-hand.

Milwaukee, Wis. EMIL M. BUEHLER.

The Cost-Plus Contract a Success

Sir—Perhaps no single administrative feature that has ever been introduced into the engineering world has attracted more attention than the now famous cost-plus contract. It has been assailed from some quarters and upheld from others, but nevertheless has forced itself into notoriety and public recognition.

An agency so powerful as to disrupt the peaceful equanimity of commercial practice and line up the brains of America in bitter opposition on the one side, and in unqualified support on the other, surely merits a most thorough investigation and wide discussion, that out of the chaos of conflicting opinions may be builded a sound foundation for future development.

In every cantonment and camp in the United States, the Government maintains an officer in charge of construction, known as the constructing quartermaster. As constructing quartermaster for the building of Camp Frémont, near San Francisco, and now for Fort Sill, Oklahoma, it has been my privilege to supervise construction work amounting to over $3,000,000, under cost-plus contracts covering a period of 18 months.

The cost-plus contract is just as applicable to commercial practice as it is for Army use, the only difference being that under private direction the constructing quartermaster would be known as the supervising engineer. The cost-plus contract as used by the Government has three cardinal virtues: Absolute fairness, flexibility, and centralization of power. The most important of these is the centralization of power in the hands of the constructing quartermaster, or supervising engineer in private work.

Certainly, no fairer scheme was ever devised for both the contractor and owner. The profit is fixed in proportion to the expenditure. Additions to, or subtractions from, the work can be made at will. As unlimited power to direct the work is given to the constructing quartermaster, full and absolute responsibility for its proper execution rests with him. This point cannot be too strongly emphasized. There is no dodging responsibility. If the cost-plus contract has failed anywhere, it is due to the incompetency and mismanagement of the directing head. No orders for materials can be placed by the contractor without his approval in writing; no equipment can be purchased or even rented without it. He has complete authority to order the discharge of any member of the contractor's organization, from the manager down. If the contractor pads the payroll, if materials are ordered that are not needed, if wasteful methods are allowed, the responsibility can be undeniably nailed upon one person—the *directing head.* If the directing head is competent, the proposition will work "like a charm." The success of the enterprise hangs upon the choice of the field management. The trend of modern business methods is toward centralizing authority in one person, and then holding that person responsible.

After operating under its terms in closest detail for almost two years, I am so strongly impressed with its desirability that I believe a monument should be erected to the memory of the genius who invented the cost-plus contract. In spite of all that can be said in opposition, the unassailable fact remains that the Construction Division of the Army has accomplished the greatest building task ever undertaken in the history of the world, and has done it under the cost-plus contract; an accomplishment that will ever shine forth as one of the fairest jewels of the nation's diadem of glory.

J. B. CHAFFEY,
Major Quartermaster Corps, United States Army.
Fort Sill, Oklahoma.

Suggests Practical Method for Testing Truss Bridge Members

Sir—With reference to the matter of formulas for steel columns, dealt with in recent articles and letters appearing in *Engineering News-Record,* the writer wishes to take this opportunity of drawing attention to the fact that existing column formulas are not founded on really proper tests, and that therefore engineers should not rest satisfied until such proper tests have been made, and, from the empirical rules deduced therefrom, a really sound column formula has been evolved.

No column experiments have yet been made which conform to actual conditions existing in modern bridges, as very few columns nowadays have hinged ends, and flat-end tests are likely to be very deceptive, because of corner bearing.

The opinion expressed by Charles E. Fowler in his letter on page 343 of your issue of Feb. 13, 1919, to the effect that a straight-line formula is to be desired on account of its simplicity, is to be commended, as there is every probability that an exact straight-line formula can be derived from proper tests. It is to be noted that some of the formulas given by Mr. Fowler in his letter use the $(l/r)^2$, this being a holdover from the old Euler formula, which was established for greater values of l/r than are used in practice.

With reference to Dr. Waddell's scheme for testing top-chord members by means of experiments conducted on a specially-built full-size bridge, the writer begs to make the following suggestions for a practical method for making such tests: Build a single-track Class 70 through-truss bridge, with the weak member designed for, say, Class 40 loading, so that the destruction of the weak member could be accomplished without injury

to the rest of the structure, thus facilitating repairs for repeated tests. The connection plates for the weak members should be extra strong. After the compression tests are completed a series of corresponding tests on tension members should be made, so as to determine the real efficiencies of both tension and compression members, and their comparative strengths. Unless this kind of a test be carried out, we shall never have any really reliable test data, as the existing data are, to a great extent, misleading. It is advisable that more than one value of l r should be tested for.

It should not be overlooked, in making up a design for a test structure, that there is a necessity for thorough detailing throughout, especially in connection with the weak members, so that failure will be in the form of a square break instead of being due to any insufficient detail, thus removing ambiguity. It would be advisable to build the permanent members of the trusses of the test bridge of nickel steel, so that the permanent and the weak sections would be somewhat alike, if the weak section were of ordinary structural grade of carbon steel.

The most satisfactory method of applying the load would be by means of hydraulic presses or jacks, to be applied at panel points, and all connected so that the load would be uniform. Pressure records should be automatically made. Control of the applied load by this means would be very simple and positive. It would be desirable to make tests for low values of l/r, so as to establish the necessity or otherwise for limiting intensities of stress.

Many of the tests we are relying on at the present time for our formulas were made on badly designed struts, and I venture to say that tests on properly designed struts would show up stronger than the present tendency of the profession in strut design indicates.

F. H. FRANKLAND,
Consulting Engineer.

35 Nassau St., New York City.

Regarding Details at Support of Pony Span in Cantilever Bridge

Sir—Replying to Mr. Godfrey's letter [see *Engineering News-Record* of Feb. 27, 1919, p. 441], the line of reaction of the rocker shoe is shown 5 in. from the intersection of the members supporting it, and this was subsequently changed to about 3 in. The offset was made for architectural effect and was considered justified since there was an excess of strength in the members adopted.

The section composing the tension members of the cantilever where the bend is made at the rocker consists of two 6 x 4 x ¾-in. angles, two 8 x 8 x ¾-in. angles and a 28 x ⅜-in. plate. The maximum stress is less than 7000 lb. per square inch of net section, and the inclination less than 1 in 9, which is not considered such a bad condition. There are two angles 6 x 4 x ¾ in., two angles 8 x 8 x ¾ in., with a ⅝-in. and a ⅜-in. plate on top to form a seat for the rocker, and all the rivets are ⅞-inch.

The writer agrees with Mr. Godfrey, in principle, that top-chord members should not be subjected to torsion, but fails to see any possibility of distorting the frame of the chord where its members are so heavy in proportion to the torque applied.

The bent plate at the connection of the lower member of the sidewalk bracket with the chord is a 15 x ⅜-in. plate, and the stress is about 4000 lb. per square inch.

There is no tension in rivet heads in the connection of the sidewalk brackets at the pony span, as ⅞-in. turned bolts were employed.

L. W. METZGER,
Designing Engineer, Oregon Highway Commission.
Salem. Oregon.

Long-Time Mixing Should Not Reduce Strength of Concrete

Sir—I have read with considerable interest the letter of J. O. Jones in *Engineering News-Record* of Jan. 23, 1919, p. 200. In addition to the account of the very complete tests made by Prof. D. A. Abrams discussed editorially in the issue of Nov. 28, 1918, p. 966, the results of tests made by other investigators have been published from time to time. It is of special importance to note that without exception—at least so far as the writer has knowledge—these investigators have obtained results tending to confirm the finding of Professor Abrams and lacking accord with the results described by Mr. Jones. In this connection, the tests made at Purdue University (see *Engineering and Contracting*, Vol. XLIII, Jan. 27, 1915,) and those made by the Pennsylvania State Highway Commission, are of interest. Fig. 1 shows graphically the results of these tests.

Assuming the use of cement fulfilling the requirements of the A. S. T. M. specification for portland cement, it seems reasonable to assume that little, if any, impairment of the cement matrix of the concrete will result from mixing the ingredient materials 10 to 15 min. However, it is common practice to specify 1 to 1½ min. as the mixing period after all materials are placed in the mixer drum, one-tenth the time assumed above.

In a concrete mix the cement and a portion of the water combine chemically to form the cement matrix, which ultimately binds together the inert particles of the sand and stone aggregates. Since the cement is the only active, strength-producing material entering into the mixture, it follows that, apart from the physical properties of the aggregates, the strength of concrete is dependent entirely upon (1) the proportioning of the materials, including the water, entering into the mix;

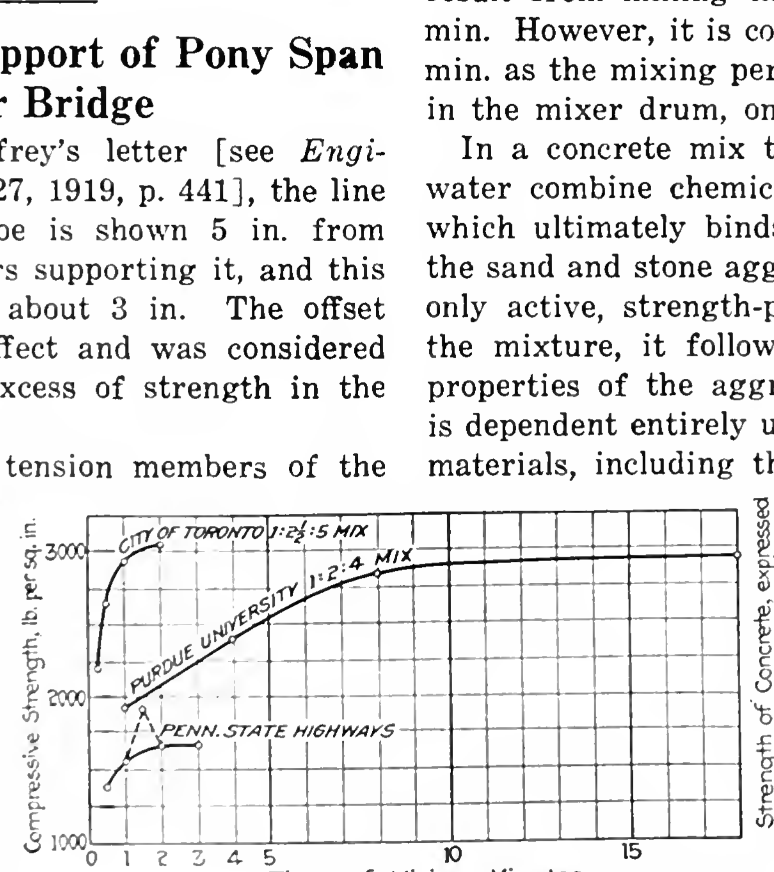

FIG. 1. THREE SETS OF TESTS ON EFFECT OF TIME OF MIXING ON STRENGTH

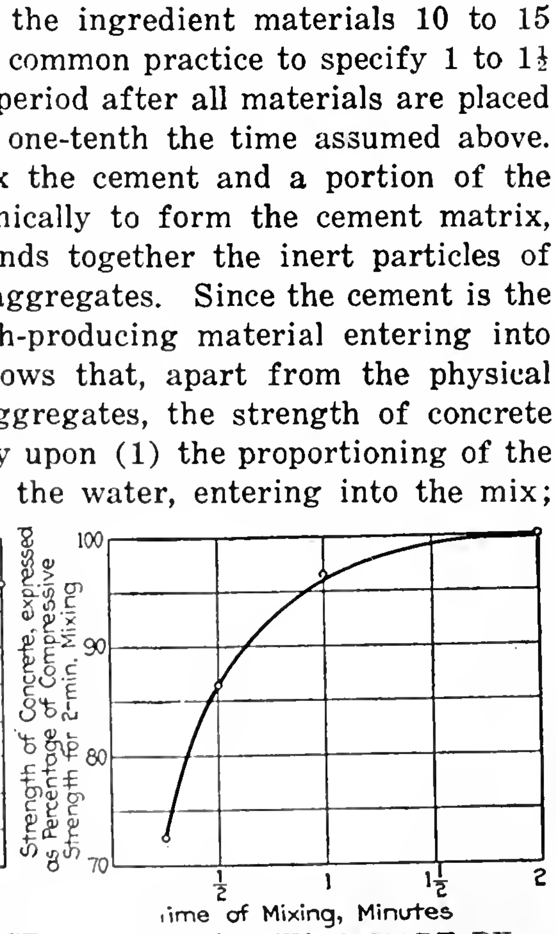

FIG. 2. TESTS MADE BY L. N. EDWARDS

(2) the thoroughness of the distribution of the cement matrix over the surfaces of the particles of sand and stone, and (3) the proper seasoning of the concrete.

The real object and purpose of mixing is the thorough incorporation of the component materials of the mix. The abrading action of the sand and stone particles moving upon each other during mixing is the most important factor tending to produce thoroughness of distribution of the cement matrix. It is commonly recognized by concrete makers that the "workability" of concrete containing sufficient water to produce a saturated, semiplastic mortar, adhering freely to the particles of stone aggregate, is improved by a comparatively long period of mixing. The writer firmly believes that the strength, toughness and durability of the concrete are also improved. Fig. 2, reproduced from his paper, "Effect of Grading of Sands and Consistency of Mix upon the Strength of Plain and Reinforced Concrete" ("Proceedings," American Society for Testing Materials, Vol. XVII) shows the relation of time of mixing to the compressive strength of concrete, as obtained in a very carefully made series of tests. In these tests a steam-operated Foote mixer of ⅓-cu.yd. capacity operated at the rate of 16 rpm. was used. All materials, including the water, were proportioned by weight.

The writer can offer no satisfactory explanation for the rather remarkable results obtained in Mr. Jones' tests. However, he is of the opinion that other factors influencing the strength of the concrete were perhaps not as carefully controlled as they might have been. Too frequently, in concrete-making operations in the field, the valves provided for gaging the water content of the mix are in bad order, and the leakage of additional water into the mixer drum during the mixing period is sufficient to offset the advantages which might be obtained by an increased period of mixing. In this connection it is worthy of mention that Professor Abrams' tests, as well as those of the writer, show that the addition of one pint of water to a one-bag batch of concrete in excess of that required to produce a "workable" mix is equivalent in its effect to the omission of 2 to 3 lb. of cement.

LLEWELLYN N. EDWARDS,
Supervising Engineer of Bridges.

Toronto, Ont.

What Was the Coefficient of Friction in the Calaveras Dam Slide?

Sir—The slide at the Calaveras dam under construction by the Spring Valley Water Co. of San Francisco, occurred Mar. 24, 1918, and was described in *Engineering News-Record* of Apr. 4, 1918, p. 679, by Allen Hazen and Leonard Metcalf. A report on the subject was also made on May 25, 1918, to the United States Reclamation Service by C. H. Swigart and the writer, which was published in the *Reclamation Record* for November, 1918, and in *Engineering and Contracting* for Jan. 8, 1919. In this report the conception of the authors of the relative position of various classes of material in the dam was described and illustrated, certain assumptions were made as to weights, and an approximate calculation was made of the forces tending to produce and resist sliding. Study led up to the following statement in the report:

> The rough conclusion which may be drawn on the basis of assumptions made is that a sliding factor of about one-half for the dry mixed rock and earth-fill used in the dam is safe, and that when this factor reached eight-tenths sliding took place.

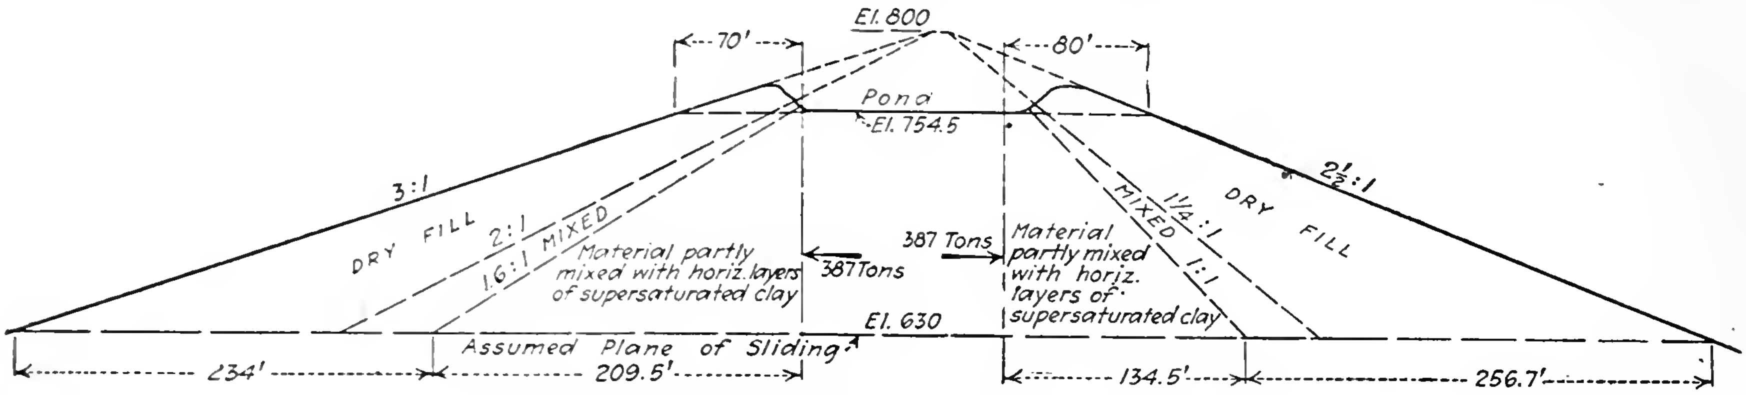
The Spring Valley Water Co. put Mr. Hazen in charge of designs for the completion of the dam. During the summer and autumn of 1918 he made an elaborate study of the materials remaining in the dam, and determined weights, water contents and stability upon which to base his conclusions as to reconstruction. He described the results of these studies in a highly interesting article published in *Engineering News-Record* of Dec. 26, 1918. Incidentally, Mr. Hazen referred in this article to the coefficient of friction of the moving material, saying, "From these figures the coefficient of friction for the whole mass at the start of the slip may be computed as 0.20."

The disparity of the values of the sliding factors 0.50 and 0.83 in the earlier report and the coefficient of friction 0.20 deduced in the later article was so striking as to attract the writer's attention at once. The investigations made after the date of the earlier report gave information which would permit revision and correction of previous assumptions, but this could hardly account for so great a difference.

A careful comparison of the respective conclusions made it promptly apparent that the values mentioned are not comparable. Mr. Hazen determined the *average* coefficient of friction for the entire base, whether consisting of dry material or slippery and partly supersaturated clay. The writers of the Reclamation Service report assumed that the wet-clay portion of the base offered very little resistance to sliding and figured all resistance as being concentrated on the portion of the base free from masses or layers of wet clay, which occupied only about one-third of the sliding base and which by reason of the flat water slope received even a smaller portion of the load. Thus they found a value more than three times greater as regards the reservoir side of the dam, which did slide, than the value found by Mr. Hazen as an average for the entire base.

The subject seemed of sufficient importance in connection with future design of dams with hydraulicked clay core to warrant restudy, and it was also deemed desirable to avoid possible confusion in the minds of readers of both articles, as to the coefficient of friction. The subject was fully discussed by correspondence with Mr. Hazen.

It may be remembered that the effort followed in construction, after it had been decided to use dry fill for the outer masses, was to place these masses as far as practicable in such manner as to have the clay core occupy two-thirds of the volume of the dam upstream from the center line and one-half of the volume downstream. This would make the clay core extend to the sloping lines 2 to 1 upstream and 1¾ to 1 downstream, as shown in the accompanying sketch. This figure represents a section of the dam as originally designed, extending downward as far as the probable level of the plane of sliding, and showing in drawn lines the approximate condition of the finished work just before the slide.



SKETCH OF CONDITIONS IN CALAVERAS DAM SLIDE

In dumping dry material so as to cause it to project over the mud pond, a considerable amount of settling took place, producing a rising pond level at times when no hydraulicking was in progress.

In the writer's previous consideration it was assumed that this process of settling resulted in some mixing of materials along planes of contact, the dry material absorbing the surplus water in the adjoining and intermingling clay and producing practically watertight mixed zones.

The width of these zones was never definitely determined. Such information as was available to the writer in May, 1918, led him to assume that these zones were comparatively narrow and that they were confined between sloping planes, as shown in the sketch.

The elaborate study given to this subject leads Mr. Hazen to conclude that penetration of dry fill into the liquid core was far deeper, and for all practical purpose extended clear down to the base. His conception is that the mixed mass was not homogeneous, but that it contained layers of pure clay supersaturated to an unknown degree, extending far out under the slopes and capable of transmitting hydraulic pressure.

As to weights of materials, the weight of loose fill deposited in 5- to 6-ft. layers, unrolled, was taken by the writer in May, 1918, at 90 lb. and of the liquid core of 83.3 lb. per cubic foot. Mr. Hazen found the weight of the loose fill to be 110 lb. per cubic foot dry and, as near as could be estimated, 120 lb. with its probable contents of moisture. He also found the unit weight of the clay core to be 100 pounds.

If the problem be considered entirely on the basis of Mr. Hazen's finding of weights, and of his conception of mixing and distribution of materials, it is evident that sliding must have taken place along some plane of deeply penetrating pure clay layer, and that one such layer must have existed near the approximate elevation of stable base. The question remains how far out from the remaining liquid core this layer of clay may have extended.

In view of the declared effort to have the core extend to the indicated slope lines of 2 to 1 and 1¼ to 1, it is here assumed that, in spite of the subsequent sinking of outer fill, some pure clay did extend at least to the slope lines 1.6 and 1.25 to 1. If this assumption, which is admitted to be arbitrary, is approximately correct, the upstream 234-ft. width of base developed material friction opposing sliding, while the remaining 209.5 ft. may have been practically frictionless.

The weight borne by the upstream portion cannot differ materially from the weight of the mass vertically above it, which figures 548 tons, as compared with 1920 tons figured by Mr. Hazen to be the weight of the entire prism, and 387 tons figured by him as the horizontal core pressure. Thus, the following values for sliding factor would result:

548 tons on dry-fill base,	387 tons horizontal pressure,	0.71 sliding factor
1372 tons on wet clay base,		0.00 sliding factor
1920 tons on entire base,	387 tons horizontal pressure,	0.20 av. sliding factor

Corresponding figures for the downstream portion of the dam are as follows:

791 tons on dry-fill base,	387 tons horizontal pressure,	0.49 sliding factor
969 tons on wet clay base,		0.00 sliding factor
1760 tons on entire base,	387 tons horizontal pressure,	0.22 av. sliding factor

On the above basis, the factors originally figured for the dry base, at 0.83 and 0.48, towards and away from the reservoir, respectively, should be amended by reason principally of different weights to 0.71 and 0.49, the former resulting in sliding, and representing the coefficient of friction of dry-fill base. The friction coefficient of the entire base was 0.20, as stated by Mr. Hazen.

It will be quite evident that different assumptions as to relative proportion of clay base will produce different results, and, as definite determination has been made impossible by the slide, no certainty as to these values can now be had.

Nevertheless, similar reasoning and approximation of forces in other dams with hydraulicked clay core may permit an intelligent comparison. The writer therefore suggests an amended rough conclusion, drawn on the basis of corrected assumptions, viz.: That a sliding factor of about one-half for the dry mixed rock and earth fill used in the dam was safe, and that when this factor reached 0.71 sliding took place.

Portland, Ore. D. C. HENNY.

How One German Military Tunnel Looks

Sir—The accompanying sketch shows a typical section of what is known as the "Crown Prince Tunnel," constructed on Mort Homme Hill by the Germans for the purpose of affording protected shelter against shell fire and for the conduct of troops to locations on the line. The tunnel was constructed in the side of the bill heading in at grade through a chalk-rock formation, with an average depth from the surface of the ground to the floor of the tunnel of about 35 ft. It could house comfortably 2500 men.

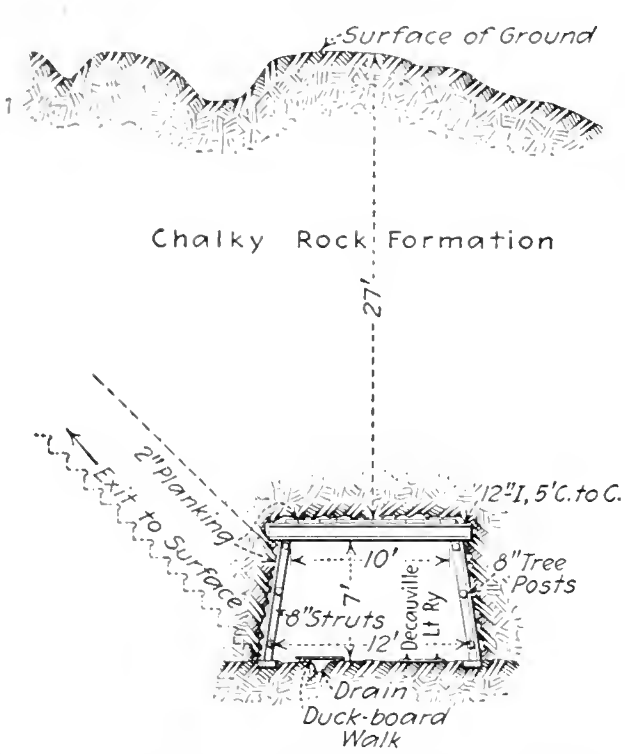
It is situated on the western slope of Mort Homme, about nine miles northwest of Verdun, and runs in a general northeast-southwest direction for a total length of about 750 m. On this hill and the adjoining hills—

No. 304, Montfaucon, Bois de Carbeaux—the greatest fighting of the war was done, and I think it no exaggeration to say that not one square foot of Mort Homme has remained unaffected by shell fire, the hill presenting to the eye one mass of contiguous shell holes and churned earth.

Mort Homme has two German-built tunnels, the Bismarck and the Crown Prince, the Bismarck being the smaller. It is said that the crown prince occasionally visited the tunnel bearing his name and, in fact, had a room therein.

The exits from the tunnel are mostly on the southerly side, marked A in the sketch, a few being on the north side, and there are openings at either end. There are about 10 exits or entrances in all, the entrance to the tunnel being accomplished by means of the northeast end.

There are a number of rooms built into the tunnel, about 10 in all. These rooms are built in the rock without impinging on the tunnel area, which is unobstructed throughout, and they average about 15 ft. square. The rooms comprise three sleeping rooms with bunks, for about 20 men, one kitchen, and a suite of rooms used as an infirmary with about eight cots in it. The infirmary is located at the northeast end, and a number of wounded and the medical staff were killed when a French shell sealed this opening. It may be well to state here that the Decauville railway cars were fitted up with a stretcher arrangement, which was



TYPICAL SECTION OF CROWN PRINCE TUNNEL, BUILT BY GERMANS ON MORT HOMME HILL NEAR VERDUN.

probably used for conveying the wounded to the infirmary from the various openings. The rooms on the northerly side were the dynamo room, with a completely equipped electric-lighting plant, which was housed in a room 12 x 24 ft. long, and another room which contained a ventilating plant of the blower type.

The tunnel is undamaged excepting at the northeast, which was destroyed by shell fire and sealed for about 30 m. At two other points near the southwest end shell fire had caused the rupture of the roof boarding, but the beams were hastily reinforced by 10-in. posts placed vertically under the center of the beams.

When this hill was finally captured by the French, 1200 prisoners were taken from this tunnel.

DANIEL I. CURTIN,
Captain of Engineers, United States Army.
Thirteenth Engineers, Verdun, France.

Construction of Three-Centered Ellipse

Sir—The accompanying diagrams and equations illustrate a simple graphical and algebraic solution for the construction of a three-centered false ellipse. Fig. 1 indicates the solution when the short radius r is known or assumed, and Fig. 2 the solution when the longer

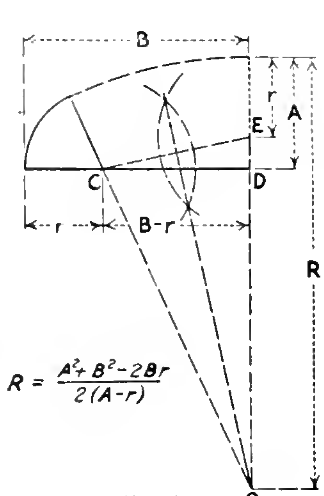


FIG. 1

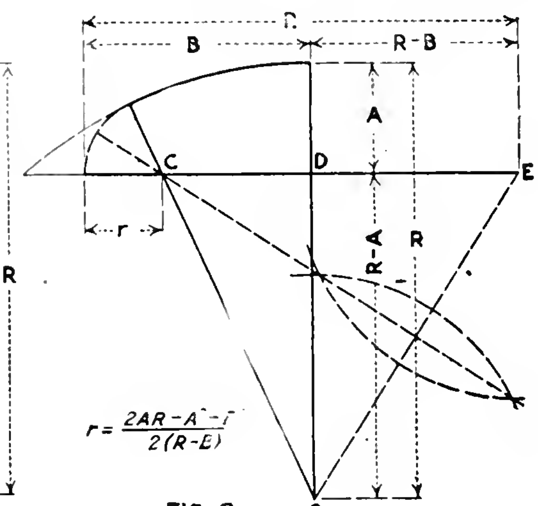

FIG. 2

radius R is known or assumed. In both cases the algebraic solution follows directly from the simple relations existing between the sides of the right triangle OCD.

The graphical construction in Fig. 1 is as follows: Lay off r on the vertical axis, locating E as shown. Connect E with center C, and erect a perpendicular bisector of CE; it will cut the vertical axis at O, the center for radius R.

Similarly, for Fig. 2: Lay off R on horizontal axis to locate E as shown, connect E with the center O, erect the perpendicular bisector of OE; it will cut the horizontal axis at C, the center for radius r.

There are other solutions, but these seem most satisfactory.

BERNHARD SILBERBERG,
Assistant Engineer, Board of Public Works.
San Francisco, Cal.

Asphalt Street Maintenance in Los Angeles

Three methods are used in repairing asphaltic street surfaces in Los Angeles, according to the annual report of the Engineering Department for the years 1917 and 1918. The methods are patch work, cover work and the surface-heating process of resurfacing. Patch work is done by the old method of cutting out and refilling. The cover work consists of cutting a binding edge around the surface to be repaired, and covering the existing asphalt surface with a thin layer of hot asphalt. The surface-heating process of resurfacing consists in heating and removing any desired thickness of the old asphalt surface, and replacing it with new. During the fiscal year covered by the report, the amount of work and the unit cost thereof was as follows: Patch work, 141,181 sq.ft. at 4.73c. per square foot; cover work, 1,012,092 sq.ft. at 3.07c. per square foot; heater work, 1,170,420 sq.ft. at 5.92c. per square foot.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

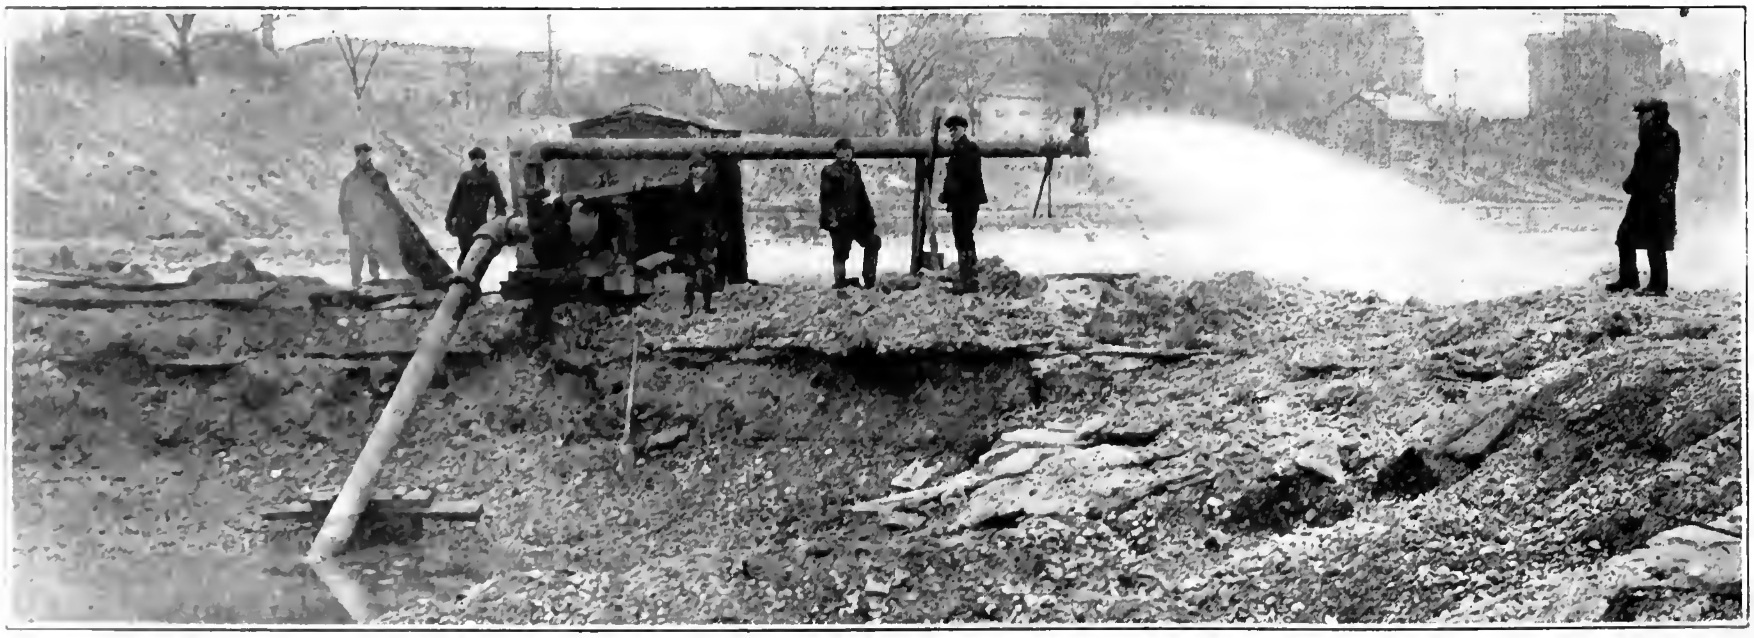
Portable Pumping Outfits Unwater Trenches for Lowering Pipe Lines

PORTABLE pumping outfits are giving excellent service in various unwatering operations in connection with the Miami Valley flood-protection works. They have been employed particularly in the work of lowering pipe lines, which has been made necessary by the deepening of the channel of the Miami River at Dayton, Ohio. Two sizes of outfits have been used for the pipe-line jobs. The smaller outfit consists of a 6-in. belt-driven volute pump operated by a 30-hp. cage-type electric motor, costing $82.50 for the pump and $416 for the motor. The larger size has an 8-in. pump and a 50-hp. motor costing, respectively, $136 and $562. In both outfits the pump and the motor are mounted on the same bed timbers, with a small weatherproof house built over the motor and a narrow roof extending over the belt to protect it from material that might drop from the buckets of excavating machinery. Four hooks in the bed timbers, to which may be attached short pieces of cable, enable the outfit to be readily lifted by crane or derrick for loading and transporting. On land the outfits were moved by motor truck and on water they have been moved on an 8 x 18-ft. general-utility deck scow.

When first sent out, the pumps were equipped with a foot valve only. On the job they were supplied with a gate valve on the discharge pipe. This valve serves two purposes: When entirely closed it retains the water for priming the pump, and when partially closed it can be made to regulate the discharge so as just to take care of the inflow into the excavation. With the pump steadily running, the gate valve can be manipulated so as to keep the water level in the excavation at any desired elevation to meet the requirements of the work.

Priming the foot valves gave rise to much difficulty. Pebbles or other obstructions would collect on the valve seat, despite the use of a strainer, and at times allow the water to flow out almost as fast as it could be poured into the pump. With a gate valve installed on the discharge pipe a more satisfactory method of priming is to pump out the air with a pitcher or diaphragm pump. The general method of procedure on the Dayton work was to excavate with the dragline machines to as near the crossing pipe as possible without damaging it with the bucket, and to build a cofferdam or low levee around the work with the excavated material. The excavating had to be carefully done on account of the weight (about four tons) and unwieldiness of the buckets. It was found that about 2 ft. is the minimum safe distance from the pipe for excavating by machine, when the work is unwatered. As soon as sufficient cofferdam had been placed the pumping outfit was swung into position by the dragline machine, a sump dug out for the suction, and the pit pumped out. As the pit was unwatered the excavation was carried down with the dragline to the desired depth on both sides of the pipe line. The pipe was then uncovered by a shovel gang, the joints were melted out with an acetylene torch, and the

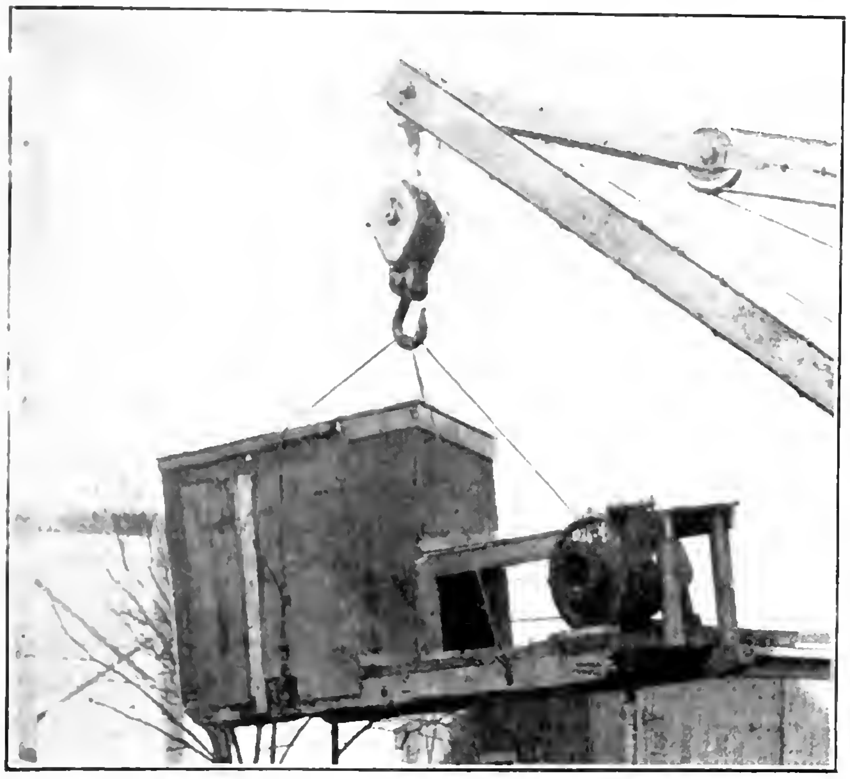
Other Articles in This Issue of Interest to Contractors:



PORTABLE PUMPING OUTFIT UNWATERING EXCAVATION FOR PIPE LINE

sections of pipe were lifted aside by the dragline machine. A new trench was excavated with the machine, and the pipe was relaid in its new bed.

On one of the pipe-line jobs a pit 200 ft. long and about 30 ft. wide at water level was unwatered to a depth of 5½ ft. in 20 min. by the 8-in. pump. The pit was kept pumped out continuously by this pump to a depth of 6 ft. below the surrounding water surface. In another instance a pit 300 ft. long and about 50 ft. wide at the water line was excavated, exposing 250 ft. of pipe line. An extra wide pit was dug in this case to provide ample working space so that the pipe line could be lowered in place without unjointing it. The material



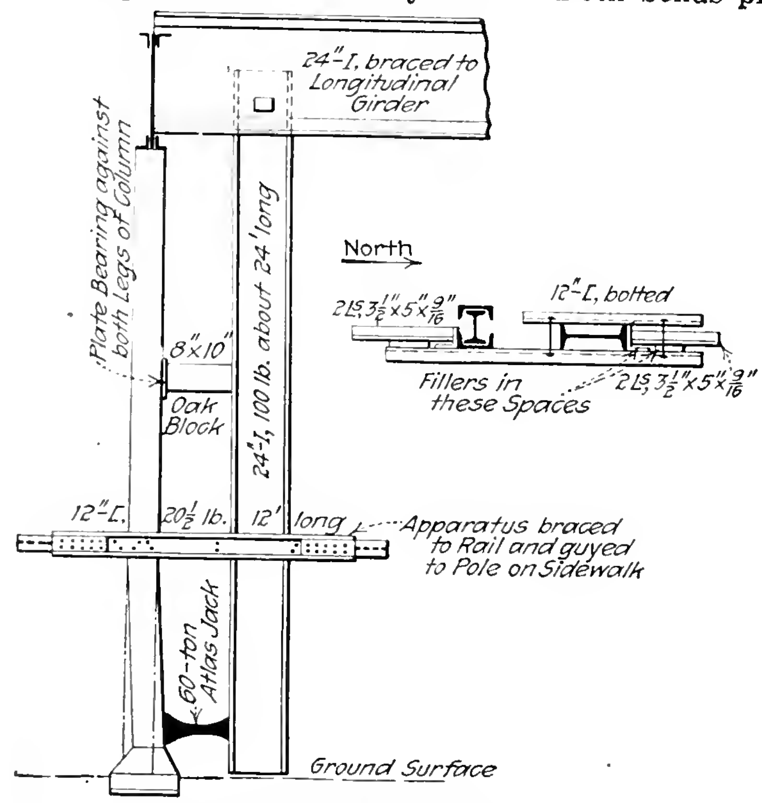
LOCOMOTIVE CRANE LOADS PORTABLE PUMPING OUTFIT ONTO MOTOR TRUCK

in this cofferdam contained considerable silt. One 8-in. pump easily kept the pit unwatered to a depth of 9 ft. below the surrounding water surface of the river.

Arthur E. Morgan is chief engineer, Charles H. Paul is assistant chief engineer and C. H. Locher is construction manager of the Miami Conservancy District.

Jack Straightens Bent Steel Column

TWO bent columns were successfully straightened in one afternoon with a device improvised from materials on the job. A railway traverses the street under the elevated line on Gravesend Ave., Brooklyn, N. Y. Shortly after the erection of the elevated structure, a girder on a passing material train broke loose from its fastenings, and, striking three columns, bent two of them and twisted the third. The twisted column had to be replaced. The more badly distorted of the two bent columns was, at the point where the girder struck it, bent out of plumb ⅞ in. on the east face and ⅜ in. on the north face. Both columns were straightened in the same manner. A 24-in. I-beam was set up and fastened to the elevated structure above and braced to the ground below. Then it was tied to the column at the bent point, as shown by the drawing. A jack was set between the column and the I-beam near the ground, and higher up a timber block was inserted. The ratio of the distance between jack and tie and tie and block was 3 to 2. Each ton pressure on the jack stressed the tie 2½ tons. Pressure was applied until the column returned to plumb and ½ in. beyond it. Both bends prac-



SCREW-JACK ARRANGEMENT FOR STRAIGHTENING BENT COLUMNS

tically disappeared in the operation. The procedure was equally successful with the second column.

The work was performed by Post & McCord, Inc., New York City, contractors for the section of the elevated road on which the accident occurred. This description is taken from an article in the *Public Service Record* by William E. Rudolph, section engineer.

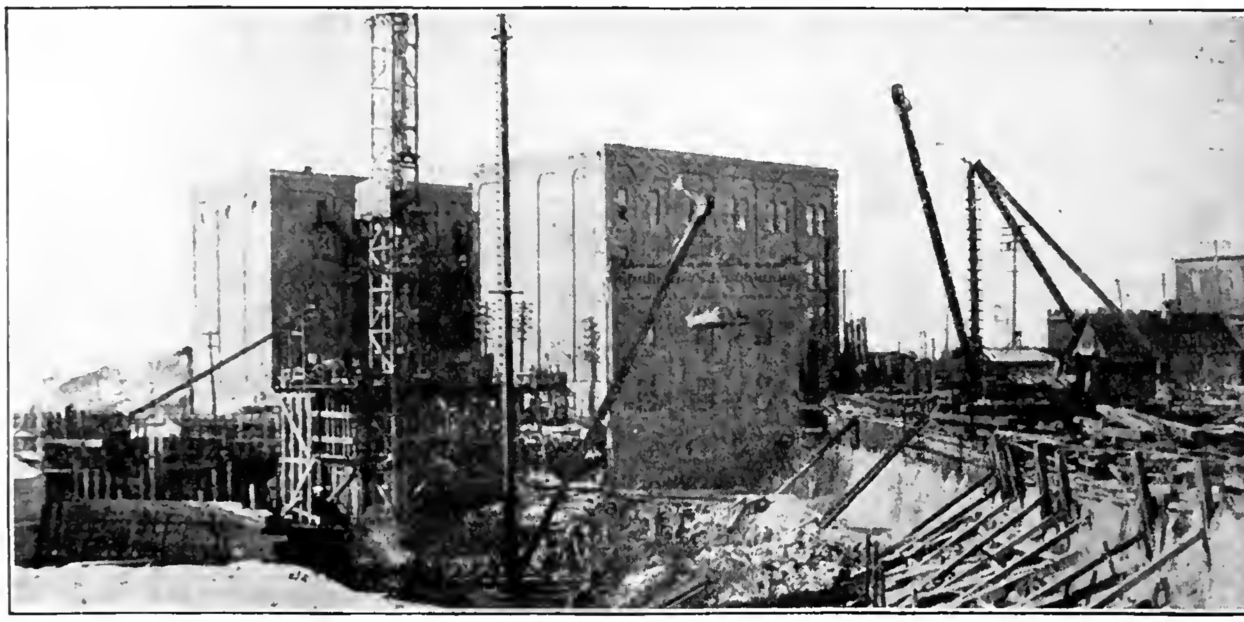
Two Derricks Operated by One Engine and Crew

IN MAKING plant arrangement for the replacing of a dam across the Mississippi River at Little Falls, Minn., the contractors, Siems, Helmers & Schaffner, of St. Paul, Minn., provided a traveling stiffleg derrick moving along the crest of the old dam, the proposed location of the new structure being such that it could be commanded in its entire length from this position. This derrick was equipped with a three-drum engine, fitted with an extra clutch winch for nigger-head work, regular swinging of the derrick being handled by a separate swinging engine.

After the beginning of cofferdam construction, it was decided by the owners to change the location of the new structure, moving it downstream to obtain better foundation conditions. This necessitated the installation of an additional derrick that would command the site, but also relieved the upper derrick of a considerable amount of the work which it was originally figured to do. The contractors therefore provided a guy derrick with an 80-ft. mast and a 70-ft. boom, set on a skid to facilitate its being moved from time to time to command the various portions of the operation.

The boom fall line was taken off the original stiffleg derrick and replaced with a fixed boom fall. With the aid of extra blocks, this left the stiffleg derrick in its original position with a fixed boom reach, one engine-

operated load line and the swinging arranged to be done by nigger-head lines. This permitted the continued use of this derrick for landing form sections, steel and other material from the contractor's yard above the dam. The remaining two engine lines were used respectively for boom fall and load line in the guy derrick, with the swinging engine rigged to do the swinging. The original location of the stiffleg derrick gave the operator an unobstructed view of both rigs.



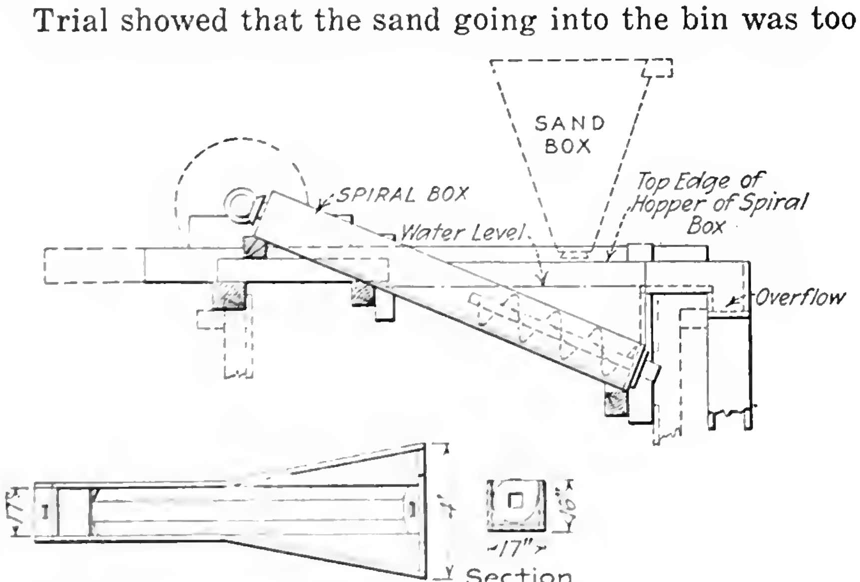
TRAVELING STIFFLEG DERRICK MOVES ALONG CREST OF OLD DAM

After the completion of the work in the river bottom, the guy derrick will be removed and the stiffleg derrick rereeved as originally installed and used for tearing off the crest of the old dam. R. D. Thomas, of Minneapolis, was consulting engineer.

Screw Conveyor Rids Washed Sand of Surplus Water

ATTACHMENT of a simple screw conveyor device to the gravel and sand-washing and screening plant at the Lockington dam of the Miami Valley flood-protection works has successfully eliminated the surplus water carried into the washed-sand bins. The washing and screening plant is of the standard construction employed on the protection works, as described in *Engineering News-Record* of Oct. 10, 1918, p. 680. The sand, wet from washing, flows down the sand screen into an inverted cone hopper which it nearly fills. Most of the contained water rises and overflows through a notch in the top edge of the cone. As the cone becomes full, a counterweighted bottom valve opens and lets the contents fall into the sand bin.

Trial showed that the sand going into the bin was too wet, and to remove this excess water the device illustrated was attached. Now the sand discharged from the cone falls into the screw conveyor hopper, whence it is carried by the screw conveyor up the inclined conveyor box, and from the top falls into the bin. As the sand is carried upward the water drains back into the hopper and, overflowing a notch in the hopper top, is carried away. The device has been found to work effectively.



EXCESS WATER DRAINS FROM WASHED SAND ASCENDING INCLINED CONVEYOR

The Miami flood-protection work, of which the Lockington dam is a part, is being carried out under the direction of Arthur E. Morgan, chief engineer, Charles H. Paul assistant chief engineer, and C. H. Locher, construction manager.

Guard Rope Against Freezing and Prevent Possible Accidents

MANILA or other fiber rope is made brittle by freezing, and should be thawed before being used. Accidents happen because of the neglect of this precaution.

Few contractors try to care properly for fiber rope; neglect of handy rope and of rope used for tackle is particularly flagrant. Fall rope and that used in standing rigging do not absorb much moisture, soon dry out in the wind, and are comparatively free from dirt. They need no special care to prevent freezing. With general utility rope the case is different. A manila rope contains only a small amount of natural moisture, but it will absorb as much as 30 to 40% in a damp atmosphere.

The moisture does no injury, but the freezing of the contained water makes the fibers brittle and the rope weak; therefore the frost should be thawed out before the rope is used subsequently for heavy lifts or pulls.

Dirt is objectionable chiefly because it reduces the working life of rope. When working, the rope fibers move and play on each other and the grit in the dirt cuts and frays them rapidly. On a construction job a visitor recently had to pick his way over the tangle of handy rope and tackle left lying where last used, and frost was in every inch of this rope.

When finished with a rope put it where it will not freeze or be ground into the mud; if this is impracticable coil down the rope and set this coil on a pile of boards or on any other handy object, so that it will have some chance to dry. C. S. H.

NEWS OF THE WEEK

New York, March 6, 1919

Reconstruction in France To Be Delayed for Year

A correspondent with good sources of information writes to *Engineering News-Record* as follows, with reference to reconstruction in France:

"Reconstruction will be a matter of at least a year hence. The work has not even been organized, and with the French habit of talking a thing to death before actually doing any work, the prospects for a speedy beginning are anything but bright."

Civil Engineers' Branches Studying Development Work

Both the Philadelphia and the Pittsburgh Associations of Members of the American Society of Civil Engineers have appointed committees paralleling the subcommittees of the Development Committee of the society. These committees have drafted reports which will be the basis of discussion regarding recommendations to be made by these local associations to the Development Committee. The Pittsburgh Association's committees reported last month, and the Philadelphia Association's committees reported Mar. 3. The number of topics being so large that they could not all be discussed at the last meeting, the Philadelphia Association will finish the discussion on Apr. 7, the committees' report meanwhile being put in type for the information of the members.

Congress Passed Few Bills That Interest Engineers

Only two bills of the many concerned with engineering matters were enacted in the deadlock that marked the final days of the 65th Congress. These are the rivers and harbors bill carrying an appropriation of $37,000,000 for construction and maintenance and also the provision for an investigation of the St. Lawrence River navigation route, noted on this page, and the bill appropriating $10,000,000 for the purchase of the Cape Cod Canal. Among the many bills and parts of bills that died were the water-power and the coal and oil lands leasing bills, the appropriation of $750,000,000 for the railroads, Secretary Lane's proposed appropriation of $100,000,000 for the reclamation of land for the use of soldiers, Senator Kenyon's emergency public-works commission, the Caldwell amendment providing that excess Government machine tools be turned over to the colleges, and the entire Army, Navy, sundry civil, public buildings and general deficiency appropriation bills. The bill validating the informal war contracts was passed and the machinery for its operation is now being put into motion. The daylight-saving law remains in force, as the amendment to the agricultural appropriation bill repealing the law failed with the bill.

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Professional and Special Section, United States Employment Service; Thomas T. Read, manager Eastern zone, 16 East 42nd St., New York, and Ward R. Robinson, manager, Central and Western Zone, 63 E. Adams St., Chicago.

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

American Association of Engineers, F. H. Myers, manager, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Appoint Reconstruction Advisory Committee

In response to a request from Chairman Abram I. Elkus, of the Reconstruction Commission of the State of New York (office in the Hall of Records, New York City), the Engineering Council has appointed an Advisory Committee of five well known engineers: George W. Fuller, chairman; H. de B. Parsons, George F. Kunz, Paul G. Brown and L. B. Stillwell, who represent the several branches of the profession and the member societies of the Engineering Council. This committee is to confer with the commission upon public works and other engineering matters, particularly the following: (1) The proposed vehicular tunnel under the Hudson River between Manhattan Island and Jersey City; (2) water-power development; (3) sewerage and sewage disposal; (4) garbage disposal and utilization, and (5) port development.

Governors and Mayors Discuss Reconstruction Three Days

At the invitation of the President 19 Governors, the representatives of many other state heads, and 137 mayors, met this week at the White House to discuss "the proper method of restoring all labor conditions to a normal basis as soon as possible and to effect any such alterations of labor and endeavor as the circumstances may make necessary," to quote the President.

The first two days were given over to addresses by the President and his cabinet officers and reports by Governors and mayors as to conditions in their respective states and cities. The last day, the deliberations of which were too late to be noted in this issue, was devoted mainly to a consideration of the resolutions which represent the action of the conference. The Governors, for the most part, reported hopeful conditions as to labor and industry, but the mayors generally told a different story. Constructive measures were absent in the first two days, though toward the end there was a notable trend toward recommendations looking to the investigation of prices, and insistence on railroad purchasing of material.

Bill Authorizes Investigation of St. Lawrence Navigation Route

A final paragraph to the Rivers and Harbors Bill which has been signed by the President authorizes the International Joint Commission, which regulates boundary waters between the United States and Canada, to investigate what further improvement of the St. Lawrence River between Montreal and Lake Ontario is necessary to make the river navigable for oceangoing vessels. The commission is ordered further to report to the Government of the Dominion of Canda and to the Congress of the United States its recommendations for coöperation by the United States with Canada in the improvement.

Seven Bids for Devil's Lake Dam

Bids for the Devil's Lake Dam, an element in the flood-control project of Los Angeles County, California, outlined in *Engineering News-Record* of Feb. 13, 1919, p. 351, ranged from $169,908 to $239,315. Bent Bros., Los Angeles, were the lowest of the seven bidders. The contract had not been awarded at latest reports, owing to the high prices asked for cement, which was to be supplied by the county. J. W. Reagan, Los Angeles, is chief engineer for the work.

Interest at Meeting of American Road Builders Centered in Post-War Problems

Topics Included National Highways, Motor Truck Regulation, Use of Materials for Heavy Traffic, Reconstructing Roads and Bridges

New conditions due to the war, and greatly increased motor-truck traffic, received consideration in many of the papers and committee reports of the American Road Builders' Association, held last week at the Hotel McAlpin, New York City. The attendance was estimated at 1350. A national highway commission and system, regulation of the various dimensions, speed and weight of motor trucks, proper materials and their proper use for heavy traffic, and the reconstruction of pavements and bridges to carry this traffic, were dealt with in various papers, discussions and reports.

Joint Sessions of the Convention

While the convention was primarily one of the American Road Builders' Association, one day was given over to a joint meeting with the American Automobile Association, the Highway Industries Association, the National Highways Association and the National Highway Traffic Association. Practically all the papers at these two sessions dealt with national aspects of good roads and the steps that must be taken to obtain a unified national system. Most of the proceedings consisted of committee reports on the above subjects, there being only two papers read, one by George H. Pride, formerly member of the Highways Transport Committee, on the "Inter-relationship of Highways, Railways and Waterways," and an address on "National Highways," by T. Coleman du Pont of the National Highway Association. Mr. Pride predicted that hauls up to 100 miles by motor truck would be found to be profitable and would not interfere in any way with railroad or waterway transportation.

The report of the Committee on National Highways was read by E. J. Mehren, editor of *Engineering News-Record*. Mr. Mehren spoke at length in advocacy of a Federal highway commission to build, maintain and control a Federal highway system. The Federal-aid law, under which the Bureau of Public Roads now operates, was designed to promote state highway systems. The Federal money is contributed to the states and the roads are built by state road officials. There was doubt in Mr. Mehren's mind whether these officials could use this money to build a system adequate for the Federal Government, when such system would not be to the best interests of their respective states, without violating their oaths of office. State officials must build the roads in locations to serve state interests best, rather than with an eye to direct national routes.

Reports on the reconstruction and strengthening of highway bridges and roadways of trunk highways to accommodate motor-truck traffic were presented for the committees of which they were chairmen by Willis Whited, bridge engineer, Pennsylvania State Highway Department, and H. E. Breed, first deputy commissioner of highways, New York. Mr. Whited stated that the committee deemed it necessary to make inspections of all highway bridges and determine at once what should be done to strengthen or reconstruct them. All new bridges should be designed for a maximum load of 20 tons. The report made by Mr. Breed recommended that in reconstructing narrow roads for trunk highways the minimum width should be 20 ft., with an allowance of 9 ft. for each additional lane of traffic.

George H. Pride read the report of the committee on regulations covering speed, weight and dimensions of motor trucks. The committee recommended the following: Maximum weight on four wheels, 28,000 lb.; maximum speed, 15 miles per hour; maximum weight per inch width of tire, 800 lb.; maximum width of truck, 96 in.; gross length of truck, 28 ft.; maximum height, 12 ft. 2 in. Resolutions recommending the features advocated by Mr. Mehren and Mr. Pride were passed at the last session of the convention.

Road Builders' Association

Besides the abstracts on p. 464 other papers and reports may be noted.

"Recent Developments in the Construction, Maintenance and Reconstruction of Cement Concrete Pavements," was the subject of an address by A. D. Williams, former chairman of the State Road Commission of West Virginia. Among the practices which have become established recently, as outlined by Mr. Williams, are: The submerged or invisible joint to take care of expansion, and the resurfacing of old concrete roads with from 2 to 3½ in. of new concrete. The latter practice has been successful on the Western Pike in West Virginia.

Cost keeping is often carried to such a fine point by highway contractors that it loses its usefulness, according to H. P. Gillette, editor-in-chief of *Engineering and Contracting*. To be of value, costs should be found daily and weekly for each item having a contract price.

One of the liveliest discussions of the convention was precipitated by the report of the committee on the economic status of guarantees for pavements on roads and streets, read by F. P. Smith, consulting paving engineer, New York City. The committee recommended that guarantees be required for the life expectancy of the pavement without repairs. The whole theory of guarantees was opposed by many of the contractors and engineers present. It was contended that guarantees always greatly raise the cost to the city and generally involve a law suit.

Among the resolutions adopted that have not already been mentioned were: One addressed to the Secretary of War, requesting the return of all road-building regiments from overseas at the earliest possible moment; one asking for the readjustment of freight rates to favor road materials, and several advocating earliest possible resumption of all road building.

Iowa Engineers Work for Technical Publicity

State-wide organized engineering publicity, directed by a central committee, has been initiated by the Iowa Engineering Society. Activities of the publicity committee, headed by R. W. Crum, and discussed at the annual meeting Feb. 19-20 in Muscatine, include a plan of action already in operation that has transformed the society from an organization active two days a year to one in continuous operation. License legislation—indorsed by all engineering organizations of the state—society organization, hard-road possibilities and drainage problems, were other topics presented.

The publicity scheme consists mainly in energizing a local engineer in each community to the point of coming into close contact with the local editor, to prepare local material and have printed the material of state-wide interest furnished by the central committee.

"Push public work now" was an idea for which the committee asked every engineer to act as publicity agent. Resolutions to that effect were passed, put into the Muscatine paper in full, and sent by the latter's syndicate service, over the state. Further admonitions were given to talk the slogan to members of councils, boards of supervisors, chambers of commerce and influential citizens. Charles H. Young expanded the idea in his presidential address, exhorting the engineers to promote "carry-on" conventions in each community before going to a proposed state convention at Des Moines.

During the meeting a group of members of the American Society of Civil Engineers authorized a committee to take steps toward the formation of an Iowa Association of Members of the American Society of Civil Engineers. Two new sections of the state society were authorized, mechanical and electrical. A special committee on professional practice was charged with running down rumors of unprofessional conduct, bringing the alleged offenders to justice or stopping the stories; also to handle the problem of engineers' compensation. A minimum wage scale was recommended of \$200 for engineers in charge, \$175 for instrument men and \$150 for draftsmen.

The officers elected for the year are as follows: C. H. Currie, president; H. H. Dean, vice-president; C. H. Streeter and A. F. Fischer, directors; J. H. Dunlap, Iowa City, secretary-treasurer.

Wisconsin Engineers Meet

Encourage construction, prepare plans and let contracts early, and preach optimism—these were the duties with which Wisconsin engineers were charged by the speakers at the annual meeting of the Engineering Society of Wisconsin, held Feb. 21-22 at Madison. A committee on licensing was created.

War, said T. Chalkley Hatton in his presidential address, had taken hundreds of young engineers and put them in positions of responsibility which they would not have reached in many years of civil practice. The country, therefore, has a large body of engineers, men trained to new ideas of coöperation, coördination and speed of production. The only way by which the engineer can meet the higher wage and price scales is by better planning, by improving and coördinating construction methods.

A. R. Hirst, engineer of the State Highway Commission, said there are not in Wisconsin, nor in neighboring states, enough engineers, contractors and inspectors trained in road construction to build the mileage of road for which money was available and which highway officials stood ready to place under construction. This calls for the best of planning and the highest development of mechanical aids to increase output and speed.

Last Meeting of the Season Held

The third and last, and perhaps the best, meeting of the winter season of the New York Section of the American Water-Works Association was held in New York City Feb. 19. Charles R. Bettes of Far Rockaway was elected a member of the board of governors.

The development of the water-treatment motor trucks used by the American Expeditionary Forces in France was outlined, and the trucks were described, by William J. Orchard, manager of the Wallace & Tiernan Co., New York City. These trucks (*Engineering News-Record*, Sept. 5, 1918, p. 458) included a combination of mechanical filter, a chlorinating apparatus and pump and storage tanks; also pumping and chlorinating apparatus alone. Some 50 units had been delivered in France, and others had been contracted for, when the armistice was signed. In order to make it possible to operate the laboratory on the truck it was found necessary to mount the pump on springs.

Application of the chloramine process of water treatment to Esopus Creek, before it enters the Ashokan reservoir, was detailed by Dr. Frank E. Hale, director of the Mount Prospect Laboratory, New York City. Studies of compound meters prior to their possible adoption by New York City were outlined by Fred B. Nelson, assistant engineer of the Department of Water Supply.

Cuyahoga River Conservancy Commission Proposed

The county commissioners of Cuyahoga County are considering the formation of a conservancy district under the Ohio conservancy law, for the purpose of straightening the Cuyahoga River, as a preliminary to the construction of a large bridge across that stream.

Waterways and Drainage Commission Proposed for Missouri

A bill abolishing the present State Land Reclamation Department of Missouri and creating a State Waterways Drainage Commission, to consist of a lawyer, a business man and an engineer, has been introduced in the Missouri legislature. The proposed commission would have charge of all drainage districts and reclamation projects.

First National Society to Adopt Cleveland Plan

A plan for joint membership in the American Society of Mechanical Engineers and the Cleveland Engineering Society, following the general scheme adopted by the latter some months ago, is announced in *Mechanical Engineering*, formerly the *Journal* of the Am. Soc. M. E. for February, as having been adopted in principle by both societies. The tentative plan provides for a division of dues between the two societies, with a reduction of $5 in the total yearly dues previously paid. Members of the national society may join the local society without paying an entrance fee. Members of the Cleveland society, on qualification and election to the Mechanical Engineers, would pay the difference between the entrance fees of the two societies. For members new to both societies the joint entrance fee would be $25—$18 to the national and $7 to the local society.

To Sell Aircraft Materials

Completion of plans and organization to sell surplus materials, including a considerable amount of lumber and shop equipment, has been announced through the Bureau of Aircraft Production, Washington, D. C., which has charge of their disposal.

Civil Service Examinations

United States.—Superintendents of road construction, Bureau of Public Roads, Department of Agriculture, Mar. 25: Class A (candidates with four years' responsible charge of construction) $150 to $175 per month; Class B (six years' responsible charge) $185 to $225; Class C (eight years' responsible charge) $230 to $250 a month. Apply to United States Civil Service Commission, Washington, D. C., or to local office of commission for form 1312, and file before Mar. 25.

United States.—Assistant examiner, Patent Office, Washington, Mar. 26-28, and May 21-23 and July 23-25. Pay, $1500 per year. Apply to United States Civil Service Commission, Washington, D. C., or to any local office of commission for form 1312, to be filed in time to arrange for examination at place selected by applicant.

United States.—Chief physicist, qualified in aëronautics, National Advisory Committee for Aëronautics, Langley Field, Hampton, Va., Mar. 25, $3000 per year. Also physicist, $2100 per year. Apply to United States Civil Service Commission, Washington, D. C., or to any local office of commission for form 1312, to be filed before Mar. 25.

United States.—Senior highway bridge engineers, Apr. 1, Bureau of Public Roads, Department of Agriculture, Washington, D. C. Grade 1 (examination percentage above 70) $2400 to $2700 per year; Grade 2 (percentage above 80) $2800 to $3000 per year; Grade 3 (percentage above 90) $3100 to $3400 per year. Apply to United States Civil Service Commission, Washington, D. C., or to any local office of the commission for form 1312, to be filed before Apr. 1.

ENGINEERING SOCIETIES

Calendar

Annual Meetings

AMERICAN RAILWAY ENGINEERING ASSOCIATION; 910 Michigan Ave., Chicago; Mar. 18-20; Chicago.

NATIONAL FIRE PROTECTION ASSOCIATION; 87 Milk St., Boston, Mass.; May 6-8, Ottawa, Can.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

The Montreal Branch of the Engineering Institute of Canada will be addressed by C. V. Holslag, on "Electrical Welding," and by Hanbury A. Budden on "Patents and Engineering," at the meeting Mar. 13. A special meeting was held Mar. 4 at which H. H. Vaughan repeated his presidential address delivered at Ottawa, in which he reviewed the munitions industry in Canada.

The San Francisco Association of Members of the American Society of Civil Engineers held its regular bimonthly meeting Feb. 18. In the annual address of the incoming president, E. J. Schneider, he presented a "budget of suggestions" looking toward an increased membership, closer acquaintanceship among the members, and more

association activities during the coming year. To carry out these ideas, committees were appointed on membership, entertainment and public relations. The topic of the evening was "Concrete Ships," and brief talks were presented on various phases of the subject, by three speakers. Leslie W. Comyn, as president of the corporation which financed the building of the "Faith," told of the obstacles that had to be overcome in starting in the industry. Victor H. Poss, who designed the hull of the "Faith," described, with the use of slides, the details of design and construction. H. J. Brunnier, principal assistant engineer, Concrete Ship Division, Emergency Fleet Corporation, showed a large number of slides, illustrating the various types of concrete ships designed and built, and construction methods in several yards.

The New England Water-Works Association will hold its monthly meeting Mar. 12 at the Hotel Brunswick, Boston. William E. Foss, chief engineer of the Metropolitan Water Works, Clinton, Mass., will read a paper entitled, "A Brief Description of a Break in a 1200-Horsepower Turbine." M. N. Baker, associate editor of *Engineering News-Record*, will speak on "Meeting Water-Main Costs by Assessments for Benefits," followed by a discussion by Caleb M. Saville, chief engineer of the Board of Water Commissioners, Hartford, Conn.

The Engineers' Club of Philadelphia will hold an excursion Mar. 22 to the Philadelphia Quartermaster Terminal, at the invitation of Lieut. Col. E. B. Morden, Quartermaster Corps, U. S. A. C. W. Brown, of the H. K. Mulford Co., will speak on "Health Conservation," at the weekly luncheon Mar. 11.

The Utah Society of Engineers held a meeting Feb. 19 which was devoted to a discussion of the production of potash in the United States. W. D. Bonner spoke on the project of producing potash from the Nebraska potash "brine." O. C. Hart described the recovery of potash at the Brigham City cement plant.

The American Association of Engineers' railroad conference program, Mar. 17, includes addresses as follows: By H. P. Gillette on "Shall Engineers Be Paid Overtime?"; by J. L. Jacobs on "Principles and Procedure in Classification and Salaries of Railroad Engineers," and by W. W. K. Sparrow on "How Shall Proper Recognition Be Obtained?" A discussion on schedules of pay will follow the preliminary report on the subject. A member of the United States Railroad Administration has been asked to speak on the application of Order 27 and Supplements 7 and 8 to the railroad engineer. All professional engineers in railroad service, whether members of any society or not, are asked to participate.

The Northwest Master Builders' Association held its second annual convention in Seattle Feb. 20-21. Resolutions were adopted providing for a campaign for the establishment of trade schools throughout the Northwest. The following officers were elected for the year: President, J. B. Warrack, Seattle; vice-president, S. G. Morin, Spokane, and secretary-treasurer, S. C. Ericksen, Tacoma.

The Seattle Engineers' Club was addressed Feb. 20 by W. J. Santmyer, Puget Sound Traction, Light & Power Co., on "Powdered Coal As a Fuel."

Personal Notes

LIEUT. COL. WILLIAM C. HOAD, Sanitary Corps, U. S. A., who has been stationed in the office of the Surgeon General as advisory engineer on water-supply, sewage disposal, and general camp sanitation, has received his discharge from the service and has returned to the professorship of sanitary engineering, University of Michigan.

J. E. PENNYBACKER, chief of management, Federal Bureau of Public Roads, has resigned to become director of roads, American Automobile Association.

MAJ. W. D. A. ANDERSON, Corps of Engineers, U. S. A., has been appointed United States Engineer at Montgomery, Ala. Major Anderson was previously in command of the 218th Engineers at Camp Travis, with the rank of colonel, for the emergency. He was assistant to the chief engineer of the Army in Cuba in 1907 and 1908, after which he served as an instructor at the United States Military Academy.

GEORGE A. ELLIOTT, engineer, Spring Valley Water Co., San Francisco, has been appointed chief engineer of the company. Mr. Elliott has been in the service of the Spring Valley company for several years, and since the retirement of Hermann Schussler has been in charge of all construction work.

DR. F. W. MCNAIR, president of the Michigan College of Mines, has been appointed consulting engineer of the Bureau of Standards, Department of Commerce, Washington, D. C.

WILLIAM S. WILSON, supervisor of the Pittsburgh division of the Pennsylvania R.R., has been appointed division engineer, with headquarters at Oil City, Penn. He was born in 1880 and received his early education at the Central Manual Training School of Philadelphia. He entered railroad service in the construction department of the Pennsylvania Lines, and a year later was transferred to the office of the engineer maintenance of way, at Philadelphia. Two years later he was appointed assistant supervisor of the Trenton division.

HERBERT THOMAS ROUTLY, who was engaged in the carrying out of highway contracts for the New York State Highway Commission and contracts for county highway work in the vicinity of Dundas, Ont., has been appointed construction engineer of provincial highways of Ontario. He was born in Ontario in 1878, and is a graduate of the Collegiate Institute at Lindsay, Ont.

CAPT. ROBERT O. WHITEAKER, U. S. A., who recently returned from service with the field artillery in France, has received his discharge and will resume private practice in the firm of Whiteaker & Washington, civil engineers, Moore Bldg., San Antonio, Tex.

ROBERT M. KNOX, 70th Engineers, U. S. A., has received his discharge from the service and returned to his former work as general superintendent, A. Guthrie & Co., Inc., contractors and engineers, Blue Island, Ill., on their canal work for the Chicago Sanitary District.

WILLIAM C. PERKINS has resigned as chief engineer of the Dunn Wire-Cut Lug Brick Co. to become chief engineer and secretary of the Eastern Paving-Brick Manufacturers' Association.

CAPT. A. V. RUGGLES, 17th Engineers, U. S. A., has returned to this country and has received his discharge from the service. He has become engineer of construction and surveys in the Cleveland Water Department.

C. E. EDWARDS has resigned as maintenance engineer of the Yakima-Sunnyside project, United States Reclamation Service, to become district manager of the Columbia irrigation district, with headquarters at Kennewick, Wash.

L. W. DUFFEE, acting chief engineer of the Gulf, Mobile & Northern R.R., at Laurel, Miss., has been appointed chief engineer, maintenance of way department, with offices at the same point.

J. R. MCDERMOTT, 832nd Aëro Squadron, was recently discharged from the service after his return to this country, and has become assistant highway engineer of Harrison County, Ohio. He was previously field engineer for the Portland Cement Association.

D. O'HARA and A. L. SHAW announce the establishment of the firm of O'Hara & Shaw, consulting engineers, with offices in the Phelan Bldg., San Francisco. Mr. O'Hara, who was formerly consulting engineer for Jacobs & Co., New York City, recently re-

ceived his discharge from the Canadian Army, which he joined at the outbreak of the war in 1914. He was engaged in the supervision of a considerable amount of construction and engineering work for the Canadian forces on the western front, particularly in the vicinity of Ypres.

T. W. WHITE, assistant engineer, office of the bridge engineer, Canadian Northern Ry., Winnipeg, Man., has been appointed district engineer, Western District, with headquarters at Edmonton, Alta.

EDWARD C. HAYER, JR., formerly of the 29th Engineers, on duty at Washington, D. C., has received his discharge from the service and has returned to the engineering department of the Chesapeake and Ohio Ry. as assistant office engineer at Richmond, Va.

FREDERICK C. FREEMAN, first assistant chief engineer, United Gas Improvement Co., Philadelphia, has been appointed engineer of the Providence Gas Co., Providence, R. I.

ROLLIN J. WINDROW has resigned as city engineer of Waco, Tex., to engage in general contracting in that city. At the time of his appointment as city engineer he was a member of the State Board of Water Engineers, and was the first county engineer of McLennan County.

WILLIAM L. ROCKWELL, senior irrigation engineer, Bureau of Public Roads, Department of Agriculture, has been sent to Haiti to advise in irrigation development work, in accordance with a recent request of the Haitian Government.

W. H. FAIRCHILD, city engineer of Galt, Ont., has become manager of the Galt Public Utilities Commission, and will have charge of both the hydroelectric and water-works departments.

A. V. REDMOND, division engineer, Transcontinental division, Canadian Government Rys., has been appointed district engineer, central district, with office at Winnipeg, Man.

LIEUT. THORALF E. OLSON, 5th Engineers, Camp A. A. Humphreys, Virginia, previously of Trenton, N. J., having been discharged from the service, has resumed his work in the New Jersey State Highway Department as resident engineer for the state highway, with headquarters at Asbury Park.

E. N. FLOYD, who has been appointed supervisor of fire protection of the newly organized Bureau of Fire Prevention, Cleveland, Cincinnati, Chicago & St. Louis Ry. and associated lines, as mentioned in *Engineering News-Record* of Feb. 27, 1919, p. 450, was previously in charge of railway location work for the Miami Conservancy District, which he joined in 1914. Since that time he has been connected with various features of the work and was recently in charge of the railway location in the Huffman and Taylorsville basins.

H. L. VERCOE, special engineer, Canadian Northern Ry. at Winnipeg, Man., has been appointed district engineer, Prairie district, with headquarters at Saskatoon, Sask.

SAUL SHAW, maintenance engineer, Naval Aircraft Factory, Philadelphia, has resigned to become structural designer, Atlantic Refining Co., at Philadelphia.

CAPT. FRANK W. HARRIS, Engineers, U. S. A., has returned to this country and, having received his discharge from the service, is now located at Renton, Wash.

THOMAS TURNBULL, assistant chief engineer, Canadian Northern Ry., has been appointed engineer maintenance of way, western lines, with headquarters at Winnipeg, Man.

OBITUARY

MAJ. JOHN C. OSTRUP, a member of General Pershing's staff, died in New York City Feb. 28. Early in 1917 he sailed for France with the first detachment of the American Expeditionary Forces, as a member of General Pershing's staff, to which he had been assigned to advise in engineering work. He was the author of "Ostrup's Specifications." He was born in Denmark in 1864 and was graduated from the Danish Military Academy in 1885, later going into harbor work for the Danish Government. He came to this country in 1891, and since that time had been engaged in railroad and bridge work. In 1898 he was appointed engineer of maintenance, South Side Elevated R.R., Chicago, later entering the service of the Boston Elevated. He was afterward called to become professor of structural engineering at Stevens Institute of Technology, and maintained offices as a consulting engineer in New York City.

MAJ. JAMES N. HAZLEHURST, Corps of Engineers, U. S. A., previously of Chattanooga, Tenn., died in France Feb. 9, as reported in current casualty lists. He was born in 1864 and received his early education at Kirkwood Military Academy, afterward entering the service of the Memphis & Charleston Ry. as a rodman. He remained in railroad work until 1884, when he resigned as superintendent of construction, New Orleans & Mississippi Valley Ry. to enter the School of Design at Cincinnati as a student. A year later he became general manager of the Lookout Iron Works, and was also associated with the Montgomery, Ala., water-works, becoming principal assistant engineer in 1887. He afterward entered private practice and was in charge of the design and construction of many water-supply systems in the South, including those for Clarksville, Tenn., Algiers, La., St. Augustine, Fla., and Hazlehurst, Miss. For a number of years he was in partnership with Charles L. B. Anderson under the firm name of Hazlehurst & Anderson, with headquarters at Atlanta, Ga., and Wilmington, N. C. The firm was dissolved in 1911, after which Mr. Hazlehurst continued in private practice in Atlanta and Chattanooga. He entered the Army and went to France in 1917 and was engaged in water-supply work for the American Expeditionary Forces.

ROBERT E. MILLIGAN, general manager, New York Continental Jewel Filtration Co., Nutley, N. J., died in Newark, N. J., Feb. 25. He was 52 years old and had been engaged in water-supply and filtration work for the past 30 years. From 1889 to 1896 he was chemical engineer for the Continental Filter Co. of New York City, and was engaged in assisting in the design and operation of water-filtration plants in various cities. Mr. Milligan was in charge of the Continental Filter Co.'s work in St. Louis, and also represented the company in experiments at Pittsburgh. He was afterward engaged in reconstructing and improving the operation of municipal filtration plants at Quincy, Cairo, Danville and Moline, Ill., and installed a new filtration process for Vicksburg, Miss. In 1900 he became associated with the New York Continental Jewel Filtration Co., first as chief engineer, and two years later becoming assistant general manager. In 1907 Mr. Milligan was appointed general manager. During his service with the New York Continental Jewel Filtration Co. he had been in charge of and assisted in the preparation of plans for, and construction and operation of municipal filtration work in various cities, including Atlanta, Ga., Montreal, Portsmouth, Ohio, Charleston, S. C., and Scranton, Penn.

CARL STRADLEY, chief engineer of the Oregon Short Line since 1911, died at Salt Lake City Feb. 11. He was 53 years old. He entered railroad service in 1886 on surveys for the Union Pacific, and for several years was engaged in location work. For a few years he went into mining work, but in 1901 was engaged on location for the Oregon Short Line, remaining continuously in the service up to his appointment as chief engineer eight years ago. Under Government control Mr. Stradley was appointed assistant chief engineer of the Union Pacific System, under Federal Manager E. E. Calvin.

Construction and Prices: 1913 and Now

In Spite of High Costs, Contracts Let Last Month Were Only Twenty-Five Per Cent. Behind February, 1913

Nobody is in a position to state definitely just how far present construction activities are behind those of the latter pre-war years. An approximation, however, is possible by comparing the activities of, say, February, 1919, with those of the corresponding month of a typical year prior to the war. The following is a quick, brief study of February, 1919, vs. February, 1913, as gleaned from the "Construction News" pages of this magazine:

Week Ending	Water-Works	Sewers	Bridges	Streets and Roads	Industrial Works	Excavating and Dredging	Buildings	Federal Govern-ment	Miscel-laneous	Total for Week
Feb. 6, 1919										
Number of bids requested	8	4	3	26	5	7	20	34	10	117
Number of contracts awarded	2	3	3	6	10	1	14	8	4	51
Total value of contracts awarded	$58,000	$214,000	$72,000	$515,000	$5,493,000	$13,000	$1,654,000	$391,000	$166,000	$8,576,500
Feb. 13, 1919										
Number of bids requested	10	7	4	34	5	6	28	27	9	130
Number of contracts awarded	1	2	8	12	8	2	2	6	1	42
Total value of contracts awarded	$6,500	$224,000	$206,000	$1,060,000	$410,000	$109,000	$179,000	$345,000	$92,000	$2,631,500
Feb. 20, 1919										
Number of bids requested	6	4	11	33	8	9	28	27	12	138
Number of contracts awarded	2	1	3	25	21	3	11	7	5	78
Total value of contracts awarded	$287,000	$543,000	$425,000	$1,368,000	$1,311,000	$325,000	$3,534,000	$250,000	$1,398,000	$9,441,000
Feb. 27, 1919										
Number of bids requested	2	7	5	34	1	6	6	12	9	82
Number of contracts awarded	....	....	....	22	16	8	12	12	15	85
Total value of contracts awarded	....	....	....	$1,396,000	$6,377,000	$2,265,000	$2,118,000	$500,000	$541,000	$13,197,000
February, 1919										
Bids requested	26	22	23	127	19	28	82	100	40	467
Contracts awarded	5	6	14	65	55	14	39	33	25	256
Value of contracts awarded	$351,500	$981,000	$703,000	$4,339,000	$13,591,000	$2,712,000	$7,485,000	$1,486,000	$2,197,000	$34,485,500

TABLE II. SHOWING CONSTRUCTION ACTIVITIES IN FEBRUARY, 1919

existence. Let them therefore be regarded as reasonably accurate. Then in February, 1913, there were 84 more contracts let than in February, 1919, the difference in value being $18,213,000.

The money value of contracts is of secondary importance to the number of contracts let; that is, one thousand $20,000 contracts mean far greater prosperity to contractors, engineers and manufacturers than twenty $1,000,000 jobs. Therefore, it should be noted that although last month the money value of contracts let was 70% of that of February, 1913, the number of contracts let was only 25% behind.

As a matter of fact, the money difference between the two periods may be more than accounted for in the $24,000,000 worth of railway work let in February, 1913. Very little grading and track work is under way at the present time, nor has there been much in the past four years.

After glancing at Table I, the most pessimistic will concede that road work is not merely picking up but is actually moving toward a boom. Last month bids were requested on 127 new projects and 65 contracts were let, aggregating more than $4,000,000, whereas in February, 1913, the contracts awarded amounted to only $2,254,000. As for industrial work, it would be reasonable to suppose that this class of construction had already been overdone; yet, last month $13,591,000 worth was let against only $1,672,000 six years ago.

The first figures to compare are the grand totals. In February, 1913, contracts let numbered 340 and aggregated $53,058,000 against the 1919 figures of 256 contracts valued at $34,845,000 (exclusive of two $50,000,000 contracts which it would be unfair to include). Of course, these figures are not absolute. The system whereby they are collected has been vastly improved since 1913. However, the figures used for both years are, so far as the writer is aware, the most reliable of the kind in

The two tables show the jobs let in each class of construction and the money involved in the particular periods under consideration. Work in four of the classes may be regarded as being normal, in four as subnormal and in two—streets and roads and industrial works—as far above normal.

Everybody in the business of supplying or using construction materials knows that the country is far underbuilt, nor is this knowledge restricted to contractors, engineers and manufacturers of construction materials. The many who have sought dwellings and apartments have learned how stringent is the housing situation. In February,

TABLE II. SHOWING CONSTRUCTION ACTIVITIES IN FEBRUARY, 1913

Week Ending	Water-Works	Sewers	Bridges	Streets and Roads	Industrial Works	Excavating and Dredging	Buildings	Federal Govern-ment	Railways	Miscel-laneous	Total for Week (All Classes)
Feb. 6, 1913											
Contracts awarded	7	5	5	13	9	3	11	9	2	4	68
Value	$170,000	$181,000	$205,000	$421,000	$305,000	$239,000	$1,632,000	$673,000	$1,800,000	$578,000	$6,204,000

Contracts awarded	5	6	14	65	55	14	39	33	....	25	256
February, 1913											
Value of contracts	$1,059,000	$2,623,000	$1,097,000	$2,254,000	$1,672,000	$2,282,000	$14,033,000	$1,166,000	$24,240,000	$2,632,000	$53,058,000
February, 1919											
Value of contracts	351,500	981,000	703,000	4,339,000	13,591,000	2,712,000	7,485,000	1,486,000	....	2,197,000	34,845,500

1913, contracts were let for 76 large non-industrial buildings, valued at $14,-000,000. Last month only 39 such building projects were contracted for, worth $7,485,000. Last month, however, bids were requested on 82 new projects.

That building is on the increase is indicated by the following:

From Nov. 7 to 14, 1918, bids were requested on 3 new building projects; Dec. 5 to 12, on 1; Jan. 9 to 16, 1919, on 8; Feb. 6 to 13, on 28; Feb. 13 to 20, on 28. These figures are only promising. They are not satisfactory in themselves. Much more building is needed to relieve the stringent housing conditions in this country.

As for public work, there is much to be done. Sewer work is practically at a standstill. One manufacturer of sewer-pipe told the writer that were he not also a manufacturer of hollow tile he would have to borrow lunch money. This was in New York. Water-works construction is away behind, contracts let being only 5 against 33 in February, 1913. The case of bridges is more encouraging. Fourteen contracts valued at $700,000 were let last month against 19 aggregating $1,000,000 in February, 1913. The same is true of dredging work, except that the value of the 14 contracts let last month was $400,000 in excess of the value of the 19 awarded six years ago. Federal Government work still exceeds pre-war conditions.

PRICES CONSIDERED

No discussion such as this is at all complete without a consideration of prices. There is no denying that the high price schedule prevailing today is an important factor in the seriousness of the construction situation. In February, 1913, cement sold for 90c. per barrel in bulk at the mill, whereas today it is $1.90. Crushed stone at dock in New York City was 85c. to 95c. per cu.yd. for 1½ in.; 90c. to $1 for ¾ in., against the present minimum of $1.65 and $1.75 respectively. Sand was 50c. per cu.yd. It is now $1.25. Gravel was 85c. to 90c.; it is now $2 a cu.yd. Steel plates in Pittsburgh sold for $1.45 per hundred and in New York at $1.61 (future deliveries in both cases), against today's quotation of $3 in Pittsburgh, $4.27 in New York. Cast-iron pipe in New York was $24 to $25 per ton for 6-in., against $62.70 today. As for pig iron, the February, 1913, Pittsburgh prices were $18.15 for bessemer, $17.15 for basic, against present prices of $32.20 and $30. Building materials are high, but that has ceased to be the "burning question"—which is, Are they going to be lower this season? The indication is that they are not going to fall very much.

It is complacent to say that if capital holds off long enough prices will tumble. It should be borne in mind that a rapidly declining market never indicates prosperity. It is almost safe to prophesy that prices will come down, but it is extremely doubtful whether the decline will be of such importance as to warrant postponing construction work. A price collapse is quite unlikely. Furthermore, it is the last thing that anyone desires. What is fervently desired and of primary importance if prosperity is to persist is a gradual lowering of prices to more attractive levels and a quickening in the placing of contracts. There must be confidence among the several parties—the party who wants work done, the party who wants to do it and the party who wants to supply the necessary materials. When this is established there will be good business for all. A. W. W.

Auto Truck Trailer Manufacturers Effect Reorganization

On Feb. 20 there was effected in Cincinnati a reorganization of the Trailer Manufacturers' Association of America. The following firms were represented: Miami Trailer Co., Troy, Ohio; Warner Mfg. Co., Beloit, Wis.; King Trailer Co., Ann Arbor, Mich.; Martin Rocking Fifth Wheel Co., Springfield, Mass.; Freuhauf Trailer Co., Detroit, Mich.; The Ohio Trailer Co., Cleveland, Ohio; Detroit Trailer Co., Detroit, Mich.; Arcadia Trailer Corporation, Newark, N. Y.; Rogers Bros. Co., Albion, Penn.; Northway Trailer Car Co., East Rochester, N. Y.; Troy Wagon Works Co., Troy, Ohio; Trailmobile Co., Cincinnati, Ohio.

The following officers were elected: W. E. Ferris, of the Ohio Trailer Co., president; W. A. Murfey, of The King Trailer Co., first vice-president; R. C. Sykes, of The Troy Wagon Works Co., second vice-president; J. C. Endebrock, of The Trailmobile Co., secretary-treasurer. The four officers, with W. R. Bond, W. F. Jolley and C. H. Martin, who were elected, constitute the executive committee.

In regard to legislation, it was pointed out that the manufacturers have been following legislation instead of leading. The difficulty of undoing legislation when once enacted was strongly emphasized, and measures were discussed to enable the association to take the lead in constructive legislative work that will not only benefit them but be a benefit to the public as well. The best legal talent will be engaged, and a digest made of all state and municipal laws available, upon which the legal efforts will be based.

Engineering and Business Interests Unite for Export Trade

A merger of large engineering interests with equally large exporting companies in New York, which will be known as the Factory Products Export Corporation, with offices at No. 2 Rector St., has been announced. The exporting organization concerned is a consolidation of the Factory Products Export Corporation and the Manufacturers' Agents Co., Inc., which have been building up a general export and import business in the Latin-American countries and the Far East since 1914 and 1916, respectively. The engineering interests are represented by the J. G. White Engineering Corporation of New York, and the activities of the company will be engaged in a general exporting and importing of hardware, machinery, engineering supplies, and building materials. The corporation expects to be of service both to the American manufacturer and the foreign buyer.

The Factory Products Corporation has business relations already established in Argentina, Chile, Ecuador, Venezuela, Mexico, the British West Indies, China, India, French Indo-China, Siam, Burma, Ceylon, Egypt and the Hawaiian Islands. These relations will be developed more comprehensively before there is expansion into new quarters of the world.

Walker W. Vick, former receiver general of Santo Domingan customs, is president of the corporation. Its directors are Louis E. Stoddard, of Bonbright & Co., Inc., and the Marlin-Rockwell Co.; George H. Walbridge, of Bonbright & Co., Inc.; Arthur H. Lockett, of Bonbright & Co., Inc.; E. J. Kulas, of The Cuyahoga Stamping & Machine Co.; E. N. Chilson of the J. G. White Engineering Corporation; D. M. Barclay and Mr. Vick.

Bridge Builders Report 12 Per Cent. of Capacity Taken

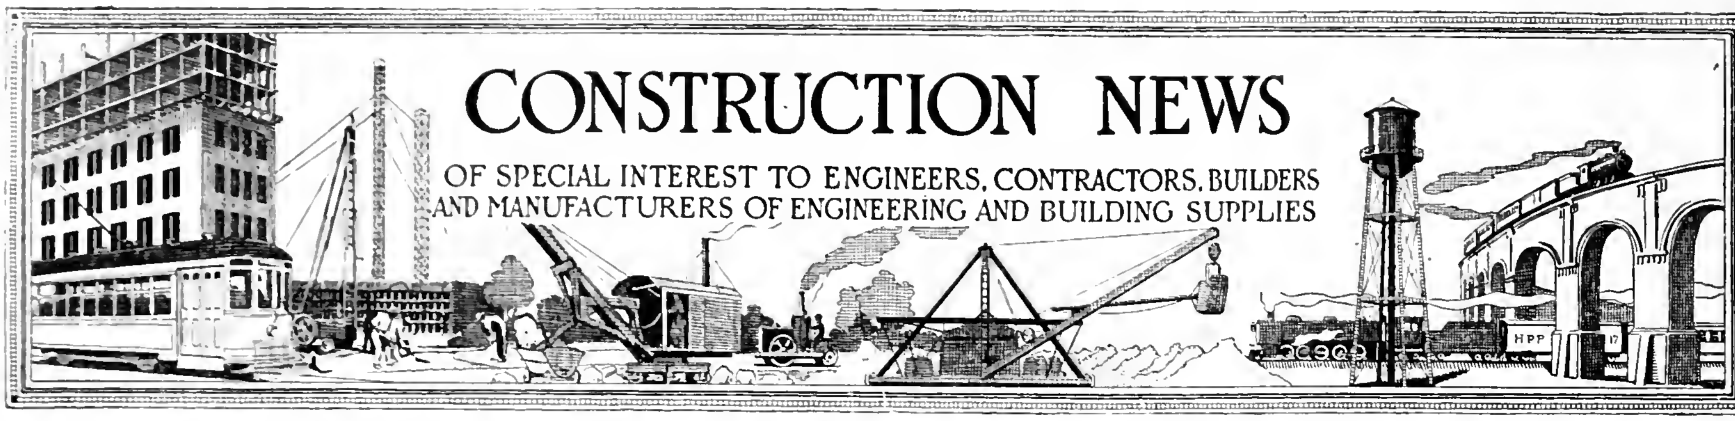
The records of the Bridge Builders' and Structural Society, as collected by its secretary, show that during January, 1919, 12% of the entire capacity of the bridge and structural shops of the country was contracted for.

OBITUARY

HOWARD P. EELLS, of Cleveland, Ohio, who until his death recently was the chairman of the Board of Direction of the Bucyrus Co., held a place of much prominence in the engineering manufacturing field.

Born in 1855, he was graduated from Harvard University in 1878, and began his business career in a Cleveland bank. In 1880 he entered the business of the Bucyrus Co., then located at Bucyrus, Ohio. In moving to South Milwaukee, Wis., to enlarge its works the company suffered from financial difficulties in the panic of 1893. Mr. Eells was appointed one of the receivers of the company, and managed its affairs so successfully that in 1898, when it was discharged from the receivership he was made its active head of the company.

When, in 1911, the company was greatly enlarged and recapitalized, Mr. Eells retired from the presidency and became the chairman of the board of directors. He remained closely interested in its affairs until his recent death.



Price advances are indicated by **heavy type**; declines by *italics*.

RAILWAY SUPPLIES

STEEL RAILS—The following quotations are per ton f.o.b. Pittsburgh and Chicago for carload or larger lots. For less than carload lots 5c. per 100 lb. is charged extra:

	Pittsburgh		Chicago	
	Current	One Year Ago	Current	One Year Ago
Standard bessemer rails	$55.00	$55.00	$65.00	$60–65
Standard openhearth rails	57.00	57.00	67.00	63–65
Light rails, 8 to 10 lb.	3.13½*	3.13½*	3.13½*	3.13½*
Light rails, 12 to 14 lb.	3.09*	3.09*	3.09*	3.09*
Light rails, 25 to 45 lb.	3.00*	3.00*	3.00*	3.00*

* Per 100 lb.

TRACK SUPPLIES—The following prices are base per 100 lb. f.o.b. Pittsburgh for carload lots together with the warehouse prices at the places named:

	Pittsburgh				
	Current	One Year Ago	Chicago	St. Louis	San Francisco
Standard spikes, 9/16-in. and larger	$3.70	$3.90	$4.50	$5.04	$6.15
Track bolts	4.90	4.90	5.50	Premium	7.50
Standard section angle bars		3.25	4.45	Premium	5.15

RAILWAY TIES—For fair-sized orders, the following prices per tie hold:

		7 In. x 9 In. by 8 Ft. 6 In.	6 In. x 8 In. by 8 Ft.
Chicago	Plain	$1.48	$1.33
San Francisco	Douglas Fir—Green	1.35	.96
San Francisco	Douglas Fir—Creosoted	2.70	*1.62*

Prices per tie at Missouri mills; St. Louis prices about 25c. higher:

Untreated A Grade White Oak 6x8x8		Untreated A Grade Red Oak 6x8x8	
No. 1	$0.70	No. 1	$0.55
No. 2	80	No. 2	.65
No. 3	90	No. 3	.75
No. 4	.98		
7x9x8 white oak			1.05
7x9x8 red oak (No. 4) $0.80		No. 5	.87

Note:—Add 36c. each for treatment.

PIPE

STEEL—From warhouses at the places named the following discounts hold for steel pipe:

	Black		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	4[illegible]%	44.9%	[illegible]%
2½ to 6 in. lap welded	[illegible]8%	40.9%	38%
	Galvanized		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	27%	29.9%	[illegible]7%
2½ to 6 in. lap welded	2[illegible]%	26.9%	[illegible]4%

Malleable fittings, Class B and C, from New York stock sell at +15% list price. Cast iron, standard sizes, 10% off.

CAST-IRON PIPE—The following are prices per net ton for carload lots:

	New York						
	Current	One Month Ago	One Year Ago	Chicago	St. Louis	San Francisco	Dallas
4 in.	$65.70	$65.70	$58.35	$64.80	$58.00	**$82.55**	*$70.00*
6 in. and over	62.70	62.70	55.35	61.80	55.00	**79.55**	*67.00*

Gas pipe and 16-ft. lengths are $1 per ton extra

CLAY DRAIN TILE—The following prices are per 1000 lin. ft.:

	New York				
Size, In.	Current	One Year Ago	St. Louis	Chicago	San Francisco
3	$35.00	$35.00	$22.50	$30.00	.....

Under the Shadow of the Railroad Problem

NEXT week the American Railway Engineering Association will hold its annual meeting. It meets at a most extraordinary time for the industry to which its labors are devoted. Last year, it is true, the railroads were under Government control. But they had only recently been taken over, policies were necessarily unformed, and the war was in progress. Now we have had over a year of Government operation. Moreover, the war being ended, the disposal of the properties has become one of the big problems of the day. The multitude of financial, legislative and regulatory questions raised by the situation will not come before the association in a formal way, but the confusion and the serious condition in which the railroads find themselves will inevitably overshadow the meeting and give it a tone more serious than would come merely from the discussion of technical questions. Moreover, the obligation which these straight-thinking men have in the rehabilitation of the railroads, which they and their predecessors have helped to create, cannot but impress itself upon them individually and collectively. Theirs is the type of thinking—the impartial analysis of all factors, even the social ones—which must prevail if the railroads are to be brought to better days. Had the thinking on top in railroad management been as solid and sane as the admirable committee work of the association, we should not have come to the present pass in railroad matters. Certainly, the work of the association looms greater now than ever, for the roads in the time of rehabilitation will have need for all the economies which engineering skill can possibly devise. That thought surely will soberly overshadow the meeting next week.

Public Work More Than Ever the Duty of the Cities

IF THE Governors' and mayors' conference at Washington accomplished little else, it certainly impressed the delegates with the necessity of getting busy each in his own city and state. No better time could have been selected for revealing the breakdown of the national Government in the reconstruction crisis. The 65th Congress was talking itself to death in a whirlwind of masterly inactivity, while the delegates were listening to depressed Federal officials explaining what they would have done had Congress acted. The President, his mind still in Paris, referred to this country's problems only to shift them onto the shoulders of the states and the cities. With few exceptions, the Governors did not show that they were alive to the situation, or that any help might be expected from them, but the mayors—being closer to the people—gave promise of action. After all, they are, in this matter, the more important of the two classes of official. Now that all hope of Federal public works for buffer employment is gone—for many months, at least—it is the cities which must step into the breach and start the street paving, the bridges, the sewers, and the water supplies, which will not only furnish work to the unemployed but give the initial impetus to business activity. No one knows this now better than the mayors of our cities. Let us hope that they will have the coöperation of every contractor and material man, particularly in giving them the best possible prices future conditions will allow. It is the duty of everyone to go as far as he can to stimulate the revival.

Enriching the Literature of Engineering

WHEN the tree is mature and its fruits are mellow, then should the fruits be picked and not be allowed to waste. Engineers and constructors there are, however, who come to maturity, who produce bounteous and splendid fruits of an intellectual and constructional kind, but never share them with others. The fruit-tree analogy is not exact, for these intellectual and constructional fruits are not wasted. They find embodiment in worthy structures. But hundreds—aye, thousands—might know of these works and profit by them, instead of the dozen who now have the knowledge. The difficulty is that these men do not take the time to record and publish their researches and experiences. This train of thought is prompted by the article by R. Fleming in this week's issue of *Engineering News-Record*. For some years Mr. Fleming has been pursuing a policy of setting down the experiences of a lifetime for the benefit of his professional brethren. The tree is mature. The fruit is mellow and of splendid quality; it is here set out that all may take and profit. Other instances might be cited, such, for example, as that wonderful article on slow-burning mill construction in *Engineering News-Record* of Dec. 27, 1917, in which F. W. Dean compressed a lifetime's experience into a few pages. But where one such instance can be cited there are, unfortunately, a dozen where experience that future generations might use will go down into the grave. Is there here not a duty as well as an opportunity? We are all heritors of the ages. Shall not the treasury of engineering knowledge be made richer because we have lived?

Grade-Crossing Problems Demand Coöperation

COÖPERATION rather than controversy should mark the solution of grade-crossing elimination, according to the Detroit report abstracted on another page. This is a principle which other cities and all

railways might well take to heart. In all such work the city gains safety and convenience for its citizens and commerce and usually an improved appearance along the railway lines. The railway gains by saving continual expense for watchmen, gates and damages, and also in freedom of operating its traffic. Certainly, as the report says, the city should pay a fair share of the expense on the ground that systematic elimination of grade crossings is a general public improvement. Discussion of principles and general policy rather than of details is a characteristic of this report which adds to its weight and value. Much of the matter applies to the problem in general as well as to the local condition of Detroit, and it would be well for other cities which have this problem before them to investigate it in the same broad and comprehensive manner.

Compensation Laws and Accident Prevention

THE economic urgency of greater safety in construction is made clear by the steady progress of the movement to compensate industrial workers for accidents, without suits to prove negligence of employers. According to a bulletin recently published by the United States Bureau of Labor Statistics six new states adopted compensation legislation during 1917 and 1918. Only 10 states are now without such legislation. Naturally, compensation laws vary greatly in character, and some of them are partial and crude, compared with others. All, however, place the burden of cost for accident squarely on the employer. To reduce the frequency and severity of accidents and thereby reduce the charge against his business for accident compensation, is the employer's problem. Contractors need particularly to visualize this fact. Construction has been the laggard among industries in practicing accident prevention. This is not because contractors are callous to humanitarian appeal. Nor is it because they are not aware of the responsibilities which workmen's compensation laws place upon them. It is chiefly because they have not been convinced that systematic safety engineering costs less than accidents. Partly, also, it is because few contractors know just what procedure to follow to educate their organizations and their workmen in "safety-first" practices. In both these problems, contractors can obtain material help from the Construction Section of the National Safety Council, whose headquarters are in Chicago.

The Railroad Plans Before Congress

IN EVERY quarter the railroad problem is recognized as one of the biggest and most pressing of the day, for it involves not merely the rights and property of thousands of citizens but the welfare of the entire community as well. Consequently, it was to be expected that when Congress, through one of its committees, announced that it was ready to hear all parties at interest, many plans and much opinion would be offered. To most of us the multiplicity of plans is confusing. Fortunately, one who has followed the testimony closely, who has studied and compared the various plans and whose standing and long railroad experience give to his words unusual weight, has prepared a discussion of the merits of the outstanding features of the various plans. It appears on p. 504 of this issue.

A presentation of each of the principal plans in detail would, naturally, run into much space. Mr. Fritch has chosen, accordingly, the logical procedure of taking up those points which are common to a number of suggestions, arguing that the greater merit is likely to rest with the plans emanating from the majority of thinking proponents. As a result of his discussion, Mr. Fritch leaves us in possession of a composite plan, covering all of the chief phases of the problem.

That plan, as he sets forth, is calculated to safeguard the rights of the two parties to the controversy—the owners of railroad securities, on the one hand, and the public, on the other. It provides for private ownership (a feature, happily, that was strongly endorsed at the recent White House conference of Governors and mayors) but for close Government control. The latter is designed to protect the public's interests, while those of the stock and bondholders would be taken care of in the valuation and in the guarantee of a reasonable return.

The problem, obviously, is not one easy of solution, nor is there likely to be much good result from a multitude of suggestions until these have been boiled down, compared and digested. As a contribution toward a better understanding of the problem as it now stands before the Congressional committee, Mr. Fritch's analysis and discussion are a most helpful addition.

Engineers' Salaries vs. Mechanics Wages

ILLUSTRATING the relation between salaries being offered engineers and the wages thought necessary to attract miscellaneous clerical and mechanical workers, a subscriber sends us some "Help Wanted" advertisements from the New Orleans *Times-Picayune*. The first item reads: "Man with knowledge of civil engineering: must own or control surveyor's instruments; to make plans and lay off surface drainage ditches and levels; prefer one familiar with concrete work; employment in city; salary $30 weekly." The second calls for a druggist and stenographer at the same salary, $30 per week; the third, for a shoemaker to do machine work at the same rate, and the fourth for shipfitters, coppersmiths and patternmakers for the Panama Canal at from $1 to $1.11 per hour.

Our first inclination was to remark that comment upon such a situation would be superfluous. However, following the lines of Mr. Goodell's letter in last week's issue, is it not worth while to distinguish in the engineer advertisement between those qualifications which require a high grade of training and those which do not? Had the advertiser omitted the words "to make plans," is it not possible that the offering of only $30 a week might secure the services of some younger man who might serve very well in the capacity and at the same time be not seriously underpaid? We think that $30 a week is far too little for a competent surveyor, but surely this compensation would appear more equitable to a man with surveying experience only than to one who had put in four years at college and had piled up experience in addition. The moment, of course, that the advertiser injected the statement that the incumbent must be able to make plans for drainage ditches he raised the requirements so materially that the salary he offers is absurd. Even so, we have heard some who would question whether the simpler jobs in civil engineering design might not be handled by men who after leaving high school had apprenticed themselves in an engineering office.

The point is that instead of condemning those who offer low compensation for minor engineering work, it is our duty to examine into the nature of the work, to analyze and distinguish as Mr. Goodell counseled, and frankly recognize which classes of work may be done with comparatively little school training and experience, and which, on the other hand, require a high degree of technical education and long experience. When we have done that and have secured a recognition among ourselves of the different elements of civil engineering work, we will be in a position to influence more intelligently the compensation that should be paid those who engage in engineering work.

Letting Road Contracts in Long Stretches

FOR some years the thought has been crystallizing that the best interests of the public would be served by letting some of our road contracts in long stretches. The past practice of short-length contracts has been due to the fact that methods were primitive, permitting the completion in a single season of only a relatively short piece of road. Quite naturally, then, the contracts tended to be limited in extent by the length of road normally laid in a season's work. This limitation, in turn, made it possible for men with small capital to take contracts, while the relative simplicity of the operations was an invitation to men of little experience to engage in road contracting.

Now conditions have changed, yet the contracting system remains relatively unaltered. In an era of expensive road types, with plant available to build rapidly, we still persist in letting contracts in lengths determined by the days of little machinery and less expensive types. The result is that there are scores of small contracts, each carried by a separate organization, while strong firms able to "plant" a job adequately and to handle a large mileage under one contract are kept out of highway work. In consequense, the public loses the savings that invariably come when a well-coordinated, big organization replaces a lot of independent, small ones.

Nor does the disadvantage lie solely in the losses due to higher costs. There is a real menace in the situation. We are embarking on a very extended highway program. This year, already promising to be of good volume, is but an introduction to a succession of years of extreme activity. The people will make the funds available to the limit of the highway engineers' ability to use them. If we persist in the methods of a bygone decade, the limitation to road-building may be serious to the whole country.

It is well known that many strong contracting organizations which have not heretofore done highway work have been studying carefully the highway-contracting situation. They are not merely ready, but anxious, to engage in this new line of work, but always they meet with the same discouragement—short-length contracts, making it impossible to cover a big mileage in one operation, and to make an investment in expensive plant. These organizations are able to take thirty- and forty-mile stretches and to put on the work one or more outfits—each costing from $30,000 to $50,000—and capable of completing a mile of road a week. With the great extension of highway improvement which is imminent, such handling is going to be inevitable, but why wait two or three years and bear the loss and setback certain with the old system?

In some places laws must be changed to permit the letting of such long contracts, but surely the people who vote large road-bond issues are willing to approve whatever is necessary for the efficient expenditure of the funds.

It must not be thought that adoption of the policy here advocated requires the elimination of all short-length highway work. In all state and county systems there are many short, unimproved sections which must necessarily be let under short-length contracts. This is particularly true of county work. In fact, it is certain that with the renewed highway activity the number of these short, unimproved sections is great enough to keep the efficient small contracting organizations hitherto engaged in highway work. These contracts, too, afford an avenue through which capable construction men can build up to the point where they, too, can take the thirty- and forty-mile stretches here advocated. Futhermore, there will always remain as inviting work for the smaller organizations the construction of the less expensive types, in which a much larger mileage can be made in a construction season than with the improved types now being used on trunk lines. We have no fear, therefore, that the adoption of a policy of long-length contracts will tend to close the door of opportunity to those now engaged in a small way in highway work or who contemplate entering this field.

It is worth while noting, too, that large contracting organizations hitherto engaged in other classes of work—such, for example, as buildings—will have much to learn if they are to execute the jobs with maximum efficiency. The type of mentality needed for success in highway construction is somewhat different from that used on building operations. On the latter work the operations are confined within a small area and can be closely supervised with relatively small overhead organization. Moreover, the compactness of the work enables one or two men to watch the sequence carefully, in order that there may be no delays between the successive phases of the operation. On highway construction the work is scattered over many miles, receiving points for materials often being located pretty far away from the actual work of laying the pavement. The type of mentality required in railway construction is more likely to fit in with highway work than is that which has hitherto attained success in such concentrated operations as the erection of buildings or industrial plants. Obviously, the wise course of procedure for big organizations new to highway construction will be to introduce into their organizations experienced roadbuilders and to support and back them with all of the resources of the large organization. Without a doubt, these big companies have much that can be added to highway work, with an assured increase in efficiency, but they have also much to learn regarding the detailed handling of pavement-construction operations.

The crux of the whole matter, however, lies in the traditional methods of letting highway construction in short lengths. Highway engineers generally, our inquiries indicate, believe in the necessity of the long-length contract, but are bound down either by legislation or by the prejudices of those in their organizations who appreciate less keenly the radical change which has come about in highway work. Under the urge of the large programs now maturing, even the conservatives may be brought to a realization of the inadequacy of past methods and adopt a policy that accords better with the new situation.

A Solution of the Railway Problem Based On Plans Presented to Congress

Discussion of the Salient and Common Features of the Various Proposals, in the Light of Experience and of the Equities Involved

By L. C. Fritch
M. Am. Soc. C. E., Past President American Railway Engineering Association, Chicago

THERE have been upward of fifty plans submitted to the Congressional committee which has been investigating the railway problem, and there will probably be many more before the investigation is closed. With all the data in hand Congress should be able to devise a plan which will embody features that will deal equitably with the various interests concerned and give effect promptly to such legislation as is necessary to place the transportation industry on a sound basis.

The natural assumption of the advocates of plans is that their particular plans are the best, but on careful analysis of the different proposals it becomes apparent that the particular interests suggesting a plan give prominence to those elements which best safeguard their interests. There are many points on which various plans agree, but not a single plan thus far proposed offers a complete and satisfactory solution of the whole problem. A composite embodying the best features of the various plans must ultimately be adopted, and in the drafting of such a plan all selfish interests must be submerged.

It is the purpose of this review to bring out the salient and common points of the various plans, to discuss them in the light of experience and of the rights and equities involved, and as a result to evolve a composite that will be fair to all.

Ownership, Control, Management, Operation

Ownership—The ownership of the railways is vested in the stockholders, representing millions of individual holders, many of them small owners, including women and children who depend upon the dividends for their support. The property rights of these people must be safeguarded, for these interests were honestly acquired.

The ownership should be left with the people—in private hands. Government ownership is recommended in only one plan, that of organized labor, and for the sole purpose of enhancing their interests without regard to the other interests concerned. Government ownership would mean a demoralization of the railway systems and make it a political spoils system with all its attendant evils. If Government ownership were made the issue before the people, it would meet with overwhelming defeat; so one is justified in concluding from the tenor of the plans presented. That which does not meet with public approval can be safely eliminated from the plan.

Corporate Organization—The ownership having been determined, the next step is the proper form of organization of the railway systems.

The predominating view is that railways should be incorporated under a Federal act. Some plans advocate that this should be compulsory, others voluntary.

One of the main difficulties confronting the railways now is the multiplicity of governing bodies controlling their operations. With the Federal Government and the 48 states making laws governing railway operation, it is plain that much confusion and expense must result. It is reasonable to expect that a single authority governing the operation of an industry which is similar all over the country would produce better and more efficient results than 49 authorities. The difficulty can only be overcome by incorporating interstate railways under a Federal act, not depriving the states of such rights as will not conflict with the Federal authority. While it is held by some legal authorities that Federal incorporation would be unconstitutional, others hold the contrary view. Certainly, if prohibition can be made constitutional by an amendment, Federal incorporation of railways, which is infinitely more vital to the welfare of the country, can be made possible.

Federal incorporation *must* be adopted to place the industry on a sound basis.

Government Control—The majority of the plans recommend some form of Government control. This principle is so well established, and has been demonstrated to be so essential, that it can be safely included in the ultimate plan. The open question is as to the form and extent of this control. The Interstate Commerce Commission is now the main Federal controlling body, but its functions are limited by law. The blame often attached to the commission for the present condition of the railways may not be laid upon the commission, but upon the law prescribing its functions. The fact remains that the commission as now constituted is not empowered to perform the functions which should belong to an adequate Federal controlling body, and it will be necessary to enlarge the powers and functions of the commission or create a new board of Federal control to meet the situation.

Various plans recommend the creation of a Department of Transportation, the head of which should be a member of the President's cabinet. It would assume the powers of the Interstate Commerce Commission. Some recommend the enlargement of the commission by creating regional commissions; others recommend no change in the present commission's organization. Strong objections are made to the appointment of a Secretary of Transportation, on the ground that it would result in political control over the transportation industry, a situation which should be avoided.

The predominating view calls for the creation of a Federal Railway Control Board with ample power to exercise public control over railways, such a board to be either an enlargement of the powers and composition of the present Interstate Commerce Commission or an entirely new body. The state commissions need not necessarily be abolished, but should act in coöperation with the Federal Board of Control, exercising such powers as are not in conflict with the Federal authority.

The public will demand and has a right to require close Government supervision over the railways.

Management—The management of the corporations should be vested in a board of directors. The composition of the board is the subject of wide differences of opinion in the various plans submitted. Several plans suggest the selection of the board solely by the stockholders, others by the stockholders and the Federal Government jointly. Again, others would require membership, on the board, of employees, representing the labor organizations.

The predominant view is that the board of directors should be selected by the stockholders and the Government jointly, and this plan will probably meet the public need of close Government supervision. If the Government representatives are chosen from among able business men throughout the country, and not by political preferment, it will result in strong business administration of the railways. The Government members should also be represented on the executive and finance committees of the boards of directors, and compulsory attendance at meetings of the board and the committees should be provided. The selection of such a board would safeguard the interests of the owners and the public and should meet with public approval.

Operation—Private operation is recommended by nearly all the plans as conducive to the best and most efficient service and economical results. The public has had a demonstration of Government operation during the present Federal control of the railways, and doubtless the conclusions reached are the results of this experience. Due consideration must, however, be given to the conditions surrounding Government operation during Federal control. The public was quite willing to endure the inconvenience and increased cost, with less efficient service, during war times, as a contribution toward the winning of the war, the paramount consideration, but it is not prepared to yield to permanent Government operation. Private operation produces results through individual initiative and incentive, which, it has been demonstrated, are lacking in Government operations.

Consolidations and Interest Guarantees

Consolidations—The consolidation or merger of the present railway systems is subject to a wide diversity of opinion in the various plans, and range all the way from a single unified system to regional systems composed of a varying number of lines. The present laws do not permit the consolidation or merger of parallel and competing lines. Therefore, it will be necessary to pass enabling legislation to perfect a comprehensive railway plan. Competition must be maintained between all important traffic centers to give the public the best service, and consolidation should not be carried to the extent of destroying this necessary competition.

The prevailing view is that the country should be divided into regions, and that within the respective regions there should be consolidation of systems, but not to such an extent as will fail to maintain competition between all important traffic centers. The plan which seems to meet the situation in the most practical manner divides the country into eight regions. In these regions, the present systems are to be consolidated into regional systems, with not less than two principal competing systems, reaching all important points, in any one region, thus preserving competitive service. This plan contemplates 17 regional systems, the nuclei of which would be the strongest lines now existing in these regions. The average mileage of the regional systems would be about 15,000, which is not excessive for efficient operation as one unit.

A careful analysis of this plan shows that such a consolidation could be accomplished with minimum disturbance to the existing systems. The 17 nuclear systems would embrace the majority of the so-called strong systems, leaving only the remainder, which form a comparatively small mileage, to be allocated to the nuclear lines. These remaining lines generally have, under the intense competition prevailing for years, operated under most adverse conditions and with uncertain results. The plan proposed would adequately provide for the future of these lines, with better service to the public and more certain financial return to the owners. It will take care of the so-called "weaker lines" and will place them beyond the financial failure and reorganization which have been their experience.

Result Will Be Financially Strong System

The strong lines are always able to provide for their needs, and if the weaker lines are protected the result will be a financially strong transportation system which will be able to serve the public with equal efficiency in all parts of the country. The community located on a "weaker line" is entitled to good service as much as that now served by the stronger roads, and under this plan the weaker lines would be a part of the stronger lines.

The plan as outlined has been developed along practicable and constructive lines and with definiteness, and seems to meet the situation more completely than any other plan respecting this particular feature.

Guarantees—A guarantee of an adequate return to meet the requirements of the railways is recommended in nearly all the plans. Some provide for a guarantee of rates adequate to protect existing investments and attract new capital; others recommend a guarantee of a fixed return upon the capital investment, but leave in doubt the method of determining the investment; others, a minimum fixed return and a division above the minimum between the owners and the Government; one plan provides for a bonus to the employees, by participating in the return.

Whether the country is prepared to guarantee a fixed return upon the capitalization of railways or to establish a level of rates for transportation which will provide a return to meet their financial requirements, the fact remains that unless one or the other means is adopted the transportation industry of the country will languish. Capital will not seek investment in railway securities unless there is some reasonable assurance of an adequate return.

The experience of the past has demonstrated the futility of depending upon a schedule of rates sufficient to meet the needs of the railways, but there is no reason why it would not be entirely practicable so to establish the rates as to meet the situation with equal justice to the public and the security owners.

There are serious objections raised to the Government's guaranteeing a return upon the capitalization of a corporation. If done for the railways, some say, why not for other industries? Others predict that such a policy would lead ultimately to Government ownership. Some have proposed that the Government

guarantee the interest upon the bonded indebtedness of the railway corporations, at the same time fixing a level of rates which will afford an adequate return upon the stock. This plan would at least protect the underlying securities and prevent embarrassment through default and receivership.

The determination of the amount of the capitalization of the railways can only be reached by a valuation of the respective properties. It will not be possible to await the results of the Federal valuation now being made, as it will be some years before that is completed. The situation demands immediate attention. It is not impossible for a fairly constituted commission of reasonable and competent men to fix this valuation in a comparatively short time.

Whichever plan of guarantee is adopted, it must form the most vital element in the problem, and unless the confidence of the public is restored in the investment in railway securities, capital will seek other channels and our transportation facilities will deteriorate.

The most acceptable plan seems to be one that will safeguard first the funded indebtedness and, second, a minimum return upon the remaining securities based upon a fair valuation to be determined in each case, giving due consideration to any expectancy values which may be found to exist. The Government will not necessarily assume any permanent financial obligation in such a plan, as it will have the power to adjust the rates of transportation so as to provide the necessary revenues.

Financial Structure and Rate Regulation

Financial Structure—The various schemes proposed to provide a new financial structure for the railways are interesting, and are mainly as follows: The new financial structure to be adjusted to such plan of rate regulation or Government guarantee as may be adopted; the consolidation of existing railway systems into a number of Federal regional corporations, which shall issue securities in exchange for existing securities, the new securities to be guaranteed from 4% to 4½% on the bonds and from a minimum of 2½% to 6% maximum on the stock, participating with the Government in excess of 6%; the valuation of railways to be ascertained by a joint commission of the Government, owners and shippers, and exchanging the present securities for new securities on an interest-yielding basis and to be guaranteed, first, interest on bonds, second, 4% on par of preferred stock, the balance of equity to accrue to common stock; the exchange of existing stocks at market value for Government bonds, which, in effect, would be Government ownership as proposed by the labor organizations.

If the owners of railway securities expect to receive a Government guarantee of a fixed return, or a guarantee by a level of rates that will produce the necessary revenue to secure that return, they must and should be willing to place their securities on a basis to which they would be entitled by sound financial rules.

This means, of course, a new financial structure for railway securities, and can be accomplished speedily and equitably, if dealt with fairly and honestly.

Three classes of securities would have to be dealt with: First, bonds or funded debt; it has been proposed that these be exchanged for new securities guaranteed by the Government at 4½% par value. The valuation of the outstanding funded debt can be readily determined and be exchanged strictly upon the basis of their actual worth. This will take care of 55% of the total railway capitalization. The owner of railway bonds could not afford to refuse a fixed income bond, even at somewhat lower interest return, for an existing security subject to the vicissitudes of present railway securities.

Second, preferred shares, which, it has been suggested, be exchanged for new 4 to 4½% securities. The preferred shares of some corporations will be found to have a value equal to or greater than the bonds. Where such values are found to exist, they can be readily dealt with on the same basis as the bonds. Preferred shares falling below the value of bonds can be treated with the common shares. The preferred shares represent 7% of the total railway capitalization.

Third, common shares; it has been suggested that these shares be entitled to the equity remaining in the property after the bonds and preferred shares have been protected. This means a valuation of the property, its earning power over a period of years, and other elements of value which may be ascertained. It would not be a difficult task to arrive at a fair and equitable basis for the exchange of these securities on a rate of return which would safeguard the investment. The common shares represent 38% of the total capitalization.

Necessary provision must also be made for existing equipment trusts, unfunded debts, etc.

It has been proposed that a corporation to be called the Interstate Commerce Corporation be organized under Federal charter to act as a clearing house for the exchange of existing securities of the railways into the new securities of the Federal regional railway systems to be organized, of which the total number for the country would be 17. These regional railway systems would arrange to acquire the securities of the various lines allocated to the nuclear roads now embraced in the larger systems, subject to the approval of the Interstate Commerce Corporation. Any railway corporation not electing to join the regional system would, of course, not be subject to the guarantee.

Would Place Securities on Sound Basis

This plan offers no greater difficulties than are usually encountered in the reorganization of any single railway system and would place railway securities upon a sound financial basis.

Rate Regulation—The courts have recognized the principle that "rates should be reasonable and sufficient to provide an adequate return on the capital invested." The Interstate Commerce Commission and the representatives of the shippers also testified before the Senate committee hearings to this effect. The difficulty lies in determining what is a reasonable rate. The burden of proof has been upon the carriers, and in most cases in the past the commission, under its rules, has suspended advances in rates indefinitely, largely because of the impossibility of proving that the rate was reasonable.

The proper solution of the question of rates is the crux of this whole matter; if the public is not prepared to establish a level of rates that will provide the neces-

sary revenue to enable the railways to exist and expand, the whole structure will fall. The people of this country are enjoying the lowest freight rate of any nation on earth—one-third that of England—and the difference between the rates necessary to enable the railways to prosper and those that are inadequate is so slight as to be almost imperceptible to the average person. It has been proposed that regional rate commissions, with proper representation of shippers, the Government and the railways, be created to deal with this question, their duty being to determine definitely the adjustment of rates necessary in any region to produce the required revenues. The final authority in rate matters would be the Federal Railway Board or the Interstate Commerce Commission as reconstituted. The question of intrastate rates now regulated by state commissions would be subject to such restrictions as to prevent discrimination against interstate rates.

The public is willing to pay rates that will provide good service, and the regional rate commissions, with all the facts before them, could readily determine what these rates should be.

Pooling—The pooling of traffic among railways under existing laws is prohibited. During operation under Federal control this restriction has been disregarded, and traffic has been routed with respect to the shortest and most available lines. This has resulted in economy of operation and has been one of the beneficial effects of Federal control. This advantage should be retained by the railways when they are returned to private operation. With a guarantee as to income, it will be immaterial to the railways whether traffic is handled by the shortest or longest route, but the public is interested in having all traffic handled as economically as possible, in order to reduce the rates to a minimum. Legislation should be provided to enable the railways to continue the benefits from pooling of traffic. On the other hand, if the plan of a limited number of regional railways is adopted, the pooling of traffic will be largely effected through the consolidation of the various lines.

Equal in importance to pooling traffic is the common use of facilities, such as terminals, trackage and equipment, which has also been one of the beneficial features of Federal control. If continued under private operation, it will result in economy and prevent the waste of capital in duplicate facilities which obtained under private operation. This can be accomplished only by a Federal control board or agency vested with jurisdiction over such matters. It cannot be and never has been done voluntarily under private control, and the public is entitled, in better service and reduced rates, to the benefits accruing from such a practice.

Labor—The labor organizations have proposed that the Government shall own the railways and operate them in one unified system, labor to reap the benefit of such operation. The defects in this plan are that it ignores the interests of the owners and the public, two vitally interested parties.

Labor is indispensable in any industry, and is entitled to its full reward; so also is the capital which is invested in the railways. Much of the capital now invested was earned by the labor of those who have been provident and put their hard-earned savings into railway securities. These investors are equally entitled to consideration. The public also, which finally pays the bills, earns its money largely by labor and deserves consideration.

Labor on railways is enjoying a higher return today than in any other industry; it should be protected in its wages and working conditions, both of which should be fair and reasonable, just as the rates should be.

The methods of dealing with railway labor organizations in effect under previous private control should be changed and regional labor commissions appointed to deal with all questions of rates of pay and rules and regulations of employment. Their findings and recommendations should be subject to the same authority as finally passes upon the rates which fix the revenue of the carriers.

Conclusions—The eleven points considered above comprise the essential and fundamental elements of the railway problem that is now demanding a solution by Congress.

Congress can solve this problem wisely and constructively and with equal justice to all, provided the various interests coöperate with Congress and approach the subject in a spirit of compromise.

Acceleration of Concrete Hardening

AS THE result of some experiments made by the Bureau of Standards to develop a method to accelerate the rate at which concrete increases in strength with age, it was found that the addition of small quantities of calcium chloride to the mixing water gave the most effective results. A comprehensive series of tests was inaugurated to determine further the amount of acceleration in the strength of concrete obtained in this manner, and to study the effect of such additions on the durability of concrete and the effect of the addition of this salt on the liability to corrosion of iron or steel embedded in mortar or concrete.

The results to date indicate that in concrete at the age of two or three days the addition of calcium chloride up to 10% by weight of water to the mixing water results in an increase in strength, over similar concrete gaged with plain water, of from 30 to 100 per cent., the best results being obtained when the gaging water contains from 4 to 6 per cent. of calcium chloride.

Compressive strength tests of concretes gaged with water containing up to 10% calcium chloride, at the age of one year, give no indication that the addition of this salt has had deleterious effect on the durability of the concrete.

Corrosion tests that have been completed indicate that the presence of calcium chloride, although the amount used is relatively small, in mortar slabs exposed to the weather, causes appreciable corrosion of the metal within a year. This appears to indicate that calcium chloride should not be used in stuccos, and warns against the unrestricted use of this salt in reinforced concrete exposed to weather or water.

The abstract of the results of the tests appear in the recently issued annual report of the Bureau of Standards.

Operation of New York Central's Cleveland Freight Terminal

Mechanical Handling Developed to High Degree of Efficiency—Use of Tractors, Trailers, Lift-Truck Platforms and Hoists

BY W. E. PHELPS

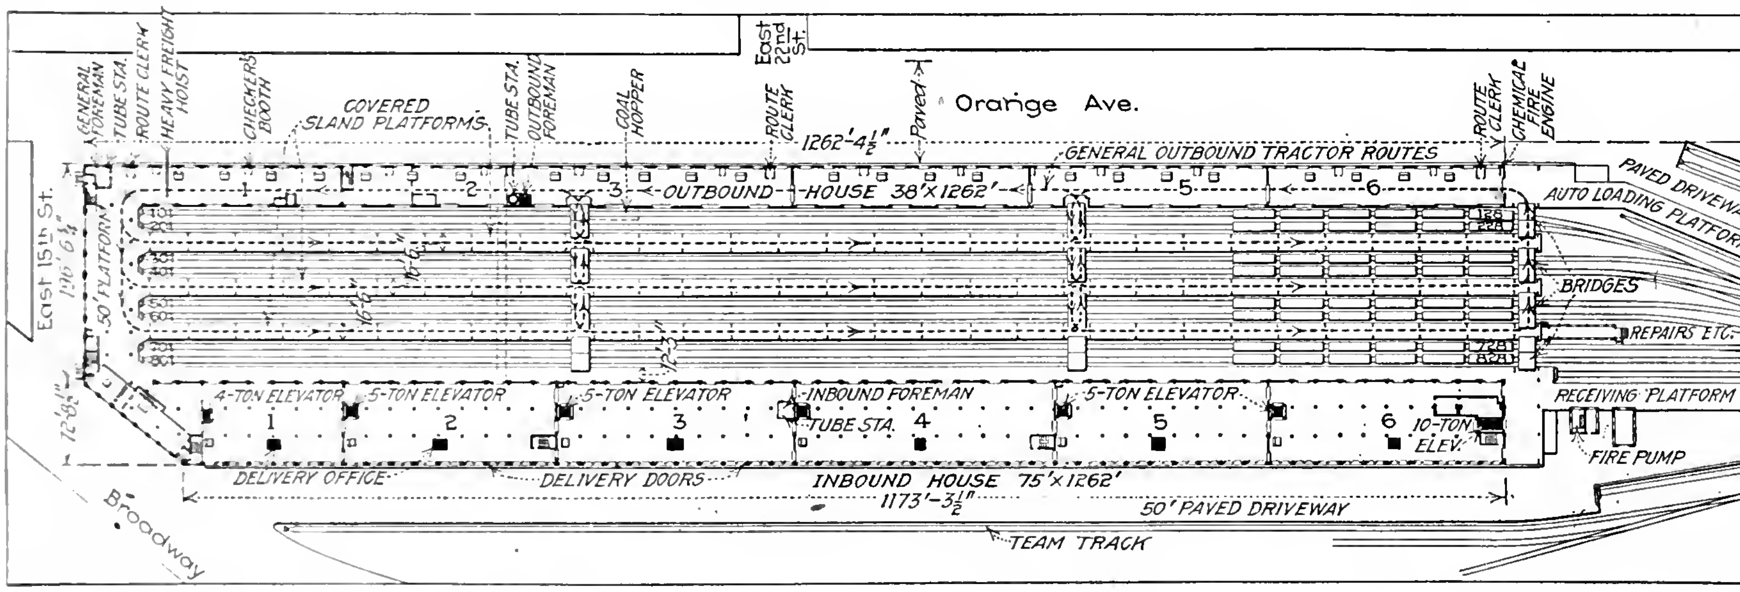
Assistant Engineer, Office of Consulting Engineer, New York Central Railroad, Cleveland

SINCE the opening early in 1918 of the New York Central Railroad's big new Orange Ave. freight terminal at Cleveland (described in *Engineering News-Record* of Mar. 14, 1918, p. 495), the railroad has met the constantly increasing shortage of labor, both unskilled truckers and experienced gang foremen, by the use of an unusual amount of mechanical equipment, and by the constant development, through experience, of highly efficient methods of freight handling. The freight is moved on four-wheel trailers and special equipment drawn in trains by electric storage-battery tractors, and a large part of the inbound freight is held, awaiting delivery, on portable platforms picked up and transported by lift trucks. Special telephone equipment facilitates intercommunication, and pneumatic tubes transmit bills and papers quickly, while the administrative systems that are employed minimize lost motion for both the patron and the railroad.

There are two separate freight houses, each 1262 ft. long, as described in the previous article, with island platforms and trucking bridges as illustrated in the plan reproduced herewith. The double-leaf hand-operated bascule wooden trucking bridges divide each track into three operating sections of nine, ten and nine cars capacity, respectively. The tracks are at street level, with the floors of houses and platforms at the height of the car and the auto truck floors. The basement and upper stories possess no feature that is special, from an operating point of view, and only the operations on the main floor will be described.

Car "spots" are numbered systematically. The first figure of the number denotes the track, and the last two figures the position on the track—as, for instance, 601 to 628 for the 28 cars on track 6. Signboards bearing the numbers are permanently posted opposite the respective positions, and cars are known in the house operations by their "spot" number. Perfectly "green" truckers digest this system of car number layout in a few minutes.

The platforms are well lighted artificially, and plug boxes for extension cords are placed at each car for use when needed; on each platform at each bridge is displayed a prominent yellow marker light to indicate to employees the location of the nearest bridge; blue lights throughout indicate fire-protection equipment; certain circuits control every fifth light on the platforms to provide switching crews and watchmen with some light for night work; the bascule bridges are automatically signalled with red and green lights.



PLAN SHOWING CONNECTIONS BETWEEN INBOUND AND OUTBOUND FREIGHT HOUSES, CLEVELAND TERMINAL

Freight handling here naturally divides itself into the two classifications of (1) outbound freight received for shipment; and (2) inbound freight shipped in for local delivery, each of which will be treated separately, as they differ materially. There is also a small amount of transfer freight handled from inbound cars to outbound cars for forwarding.

The house operating force comprises a general foreman reporting to the agent, and a foreman for each house, each with assistant foremen and clerks, with route clerks, checkers, loaders, trainmen, freight handlers, stowers, etc., handling outbound freight, and deliverymen, tallymen, pilers, callers, freight handlers, etc., handling inbound freight.

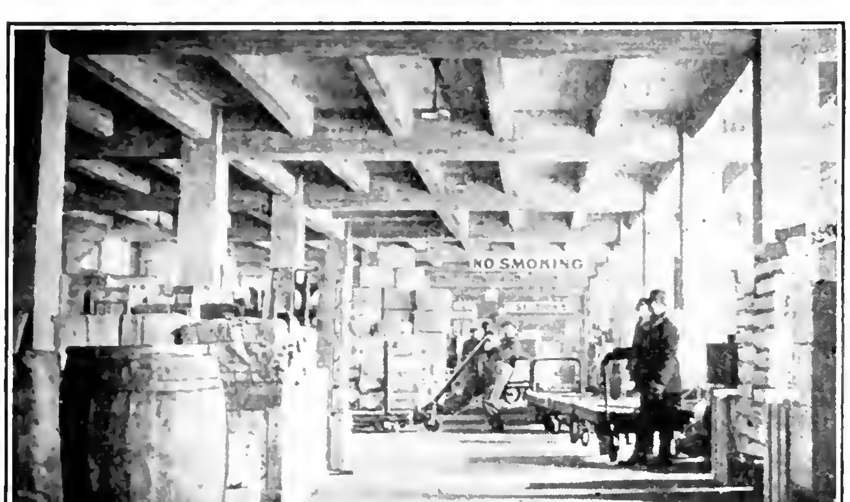
A driver with outbound freight goes first with his shipping bills to any one of three route clerks, located in special booths at the ends and center of the houses. These clerks are experts, and are supplied with all necessary routing information; they mark the shipping bills with the spot numbers of the cars into which the freight is to go, and these numbers govern the checkers in their handling of the freight; this obviates the necessity for each checker or receiving clerk routing the freight he receives (the practice at many houses), and eliminates many errors common with that system.

The spot numbers on the bills also indicate roughly to the teamster the door to which the freight should be taken, as the 56 driveway doors are numbered in groups from 1 to 28, to correspond with the car numbers. The checkers also advise teamsters where to take certain shipments, and compliance with such requests, though not strictly enforced, is fairly general and gradually improving, and results advantageously in shorter trucking hauls and greater consolidation of trailer loads for given cars.

The checker and gang receiving freight loads it generally direct from the wagon onto four-wheeled trailers (loaded for only one car—no "peddling" of freight is permitted), chalks on it the spot number already pencilled on the bills by a route clerk, weighs it on an automatic dial scale adjacent to the doorway, and shoves it out toward the main aisle, where the "despatcher" or "hooker" (one for each of the six sections) shifts the trailers around by hand into trains of six to ten or more, made up if possible with the loads at hand, for one section of one platform, and so grouped that as the tractor-drawn train proceeds the rear trailers are cut off progressively at the proper cars, and when all loaded trailers have been cut off the tractor picks up empties to take back into the house.

The train movement is westwardly in the house and eastwardly on the platforms; this single direction of movement is advantageous in many ways.

In the tractor-train operation it has proved economical to provide, in addition to the motorman, a "brakeman" to couple and uncouple, watch the train to prevent freight falling, etc., thus measurably speeding up the entire operation. Formerly, a gang of three stowers was assigned to each eight cars on the platform to handle the loading of cars, but this method has been superseded by the system, which works much better, of putting all the stowers on one platform in one gang, under the supervision of a head stower, who can intelligently direct the efforts of all the men to prevent

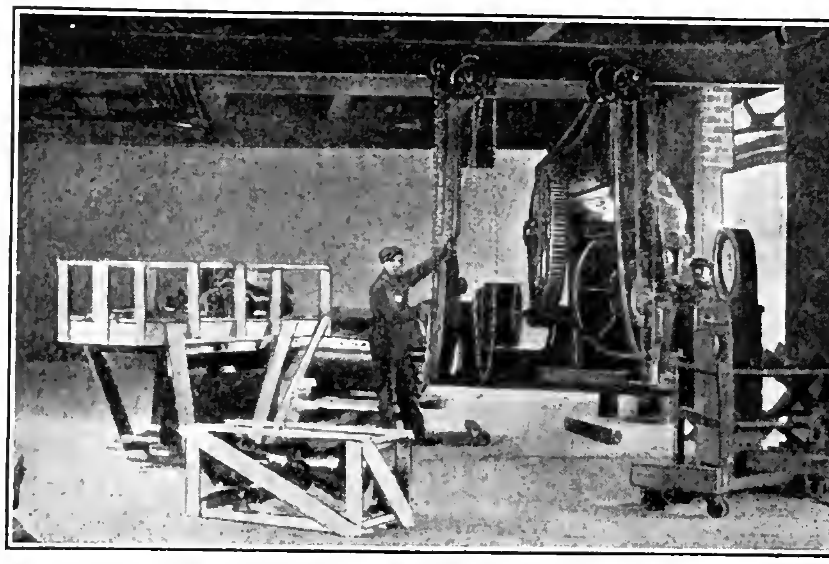


LOADED LIFT TRUCK PLATFORM AND EMPTY TRAILERS

congestion on the platforms, and is responsible for the proper loading of the cars.

The telephone installation by which the head stowers can promptly notify the foreman's office of "full cars," and the foreman's office in turn notifies all route clerks and checkers of the condition, with consequent diversions to other available cars, saves considerable backhauling of freight which would otherwise be marked for cars which would be found full when the freight reached them. This condition naturally occurs just at the peak-load time in the late afternoon, and is a fruitful source of confusion and wrong loading.

A pneumatic tube system for the handling of bills between the "checkers" and the billing department results in a uniform flow of bills into the billing office all day long, permits very prompt billing and reduces the delay in getting out bills for cars after the house is closed; this permits prompter dispatch of outbound trains.



HOIST FOR HANDLING MACHINE TOOLS, SHAFTING AND OTHER HEAVY FREIGHT

Checkers do not "shoot" their bills until the tractor has taken the freight off the floor.

The "sailing date" plan is in effect in Cleveland, and to meet this condition, with its prescribed daily change of "regular" cars which would seriously affect a "permanent set-up," a modified set-up is used, in which certain grouped spot numbers are assigned permanently to each group, consisting of cars to be set out at one certain main station or yard, with the groups arranged to meet the road operating requirements, but the arrangement within each group entirely flexible and at the option of the house forces, who may arrange it at will to meet the varying exigencies of the business.

Trains, under this arrangement, are made ready for road movement by pulling whole tracks at a time and simply kicking out the "set-backs" and switching any outbound team track cars into the groups. The westbound train, given the preference, leaves about 45 min. after the cars are sealed, the eastbound train leaving soon after. In resetting the house with empties after the outbound freight leaves, set-backs are switched back only into their proper groups, and not onto a designated "spot."

Due to the exceptionally heavy class of freight handled, consisting largely of manufactured metal goods, paints, oils, etc., the trailer loads are believed to average heavier than at any other house in the country. A week's check recently showed an average load of 1329 lb. per trailer per trip, each trailer in service averaging about six trips per day, while figures obtained from other stations have indicated an average trailer loading of 1000 lb. to 1100 lb. per trip.

The trailers used are of reinforced wooden construction, with 36 x 72-in. platforms 20 in. above the floor, with inverted U-shape removable "gates" of 1-in. pipe fitting into numerous stake pockets at sides and ends, and interchangeable on the different makes of trailers used. The main wheels are roller-bearing, of 18-in.

diameter and with 4-in. face, and the ball-bearing casters have 9-in. plain bearing wheels. These wheel sizes were selected after the undoubted merits of lower wheels as effecting easier loading conditions had been carefully considered, because of the greater difficulty of moving low-wheel trailers by hand to switch them into trains, move them into cars, etc., and the choice seems to be justified by results, as even the 18-in. wheel trailers are difficult to push around when unusually heavily loaded.

But there is some freight, notably oil and paint in barrels, which is hard to handle on and off trailers with 20-in. platforms, and for handling this class of goods

TRACTOR AND TRAILERS ON TRANSVERSE TRUCKING BRIDGE

an all-steel underslung trailer with the same wheel sizes, but with platform only 8¾ in. above the floor, is provided. A number of old two-wheel hand trucks have been converted into very serviceable trailers for barrel freight by substituting heavy double 5½-in. casters for the original rests or "feet," and equipping them with necessary chains and eye-bolts for couplers. Otherwise, the use of two-wheel trucks in handling outbound freight has been practically eliminated. The couplers on the standard trailers consist of a hook on the caster end, fitting into an eye on the main-wheel end of the trailer ahead.

Many types of dollies and similar special equipment, some of which are illustrated, are in use to handle the large number of heavy machines, etc., received; experiments are being made toward further development of equipment, for handling these heavy loads, which, among other things, will give better load distribution on the floors.

Short sections of gravity-roll carriers, mounted in frames with casters to bring one end to trailer-floor height, while the other end is placed on a discharging wagon or truck, to assist in a quick and easy transfer from wagon to trailers, are under order and are expected to help with certain classes of freight.

A hoist has been provided to handle economically heavy freight like machine tools, etc., from auto or wagon to trailers or dollies. This consists of a suspended I-beam runway extending out about 8 ft. over the driveway, and back 16 ft. into the house, with two three-ton geared trolley hoists operating independently of each other, giving a combined capacity of six tons, which can be concentrated or applied at different points on a load, as necessary; this has a clearance of 10 ft. from the floor to the hook in highest position.

Three-wheel tractors, with 30 cells of Edison A-6 battery, developing approximately 450-lb. drawbar pull, and, with a load of three or four tons, capable of a speed of five or six miles per hour, are used. Loads higher than 11 tons, including weight of trailer, are sometimes pulled, but with material reduction in speed. One load of 25 tons gross, with 21 trailers, was recently pulled 600 ft. and around two 90° turns; however, "freak" loads like this are frowned upon. This three-wheel type has a very small turning radius, and is surprisingly facile in operation. Batteries are charged at night through a motor-generator charging set, and are boosted at noon to stimulate them for the afternoon.

Inbound freight requires quite different handling, and the peculiarities of the plant have made possible more or less radical departures from usual practices. The 1262-ft. house is divided by firewalls into six sections, each in charge of a delivery foreman, under whom are two pilers and a clerk. Sections 1 to 4 are allotted to freight for firms whose business is regularly large enough to justify assignment of regular space in the house; such spaces are permanently marked by appropriate signboards. The "alphabet" sections, 5 and 6, handle freight for smaller and miscellaneous consignees. Freight for any given shipper thus goes to one designated spot in the house.

Inbound freight arrives in cars containing many and various shipments, consequently it is impracticable to place them in the house for unloading in any predetermined order to facilitate their unloading; and, as a result, the hauls on individual shipments to designated locations in the house are often long, sometimes the full length of the plant; under these conditions hand trucking proved expensive, and tractors and trailers have been substituted with markedly good results.

Trailers are loaded to capacity at the cars, with freight for one consignee if possible, otherwise with freight for one section. They are put in trains and pulled into the house by tractors and dropped off in the main aisle nearest the proper pile for unloading. All main and cross aisles in the house are plainly marked with painted 4-in. white lines, frequently renewed.

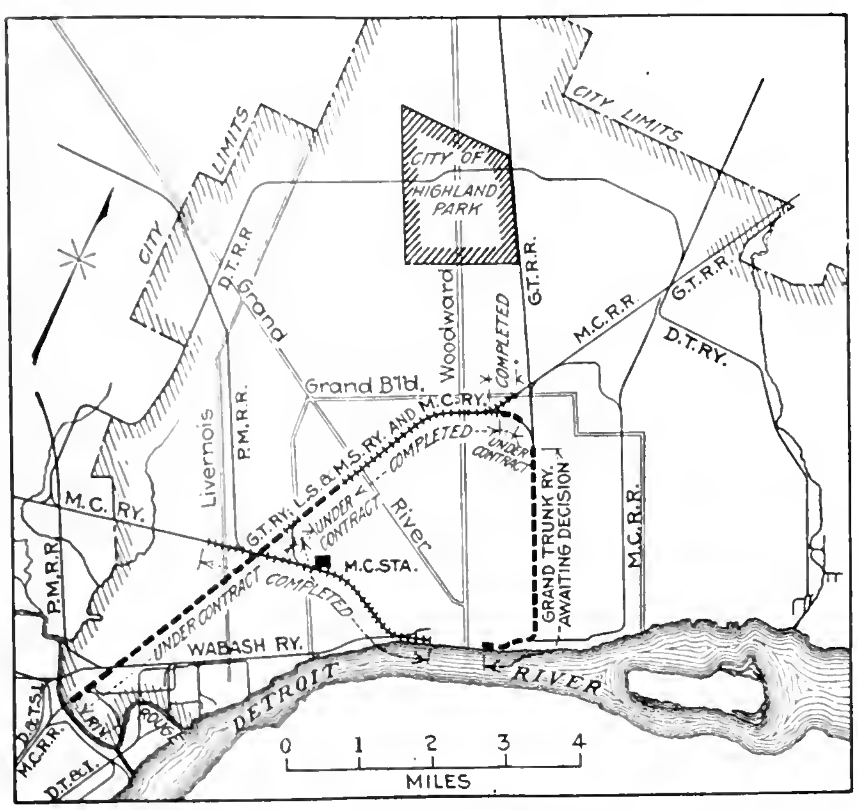
When the size of a shipment, or those of several shipments for one consignee, justify it, the freight is unloaded from the trailers directly onto a 42 x 60-in. lift-truck platform (of which there are about 60 in each section); otherwise, it is unloaded directly on the floor. These platforms are sturdily built, with stake pockets for use when needed, and a large proportion of the inbound freight is handled on them. They permit quick delivery of large loads of freight without second handling, saving labor and damage, and are enthusiastically indorsed by the operating forces. They also add to the general neatness of the house, and prevent freight from getting lost. One lift truck with 9-in. wheels, 2½-in. lift and 48-in. frame is used in each section. These trucks and platforms are used practically only for delivery of freight as above and for occasional transfer of freight to storage, etc.

Transfer of freight by trap-car from this plant to city stations of other roads for forwarding has been abandoned, and this transferring is now done by truck. Fire drills are carried out regularly by the house forces, organized into regular fire companies under the direction of a fire warden. Car-repair facilities permit light repairs and testing and cleaning of brake valves as the cars stand at the platforms, also the charging of train lines before the house is closed, thus saving time after the train is switched up ready for the road.

Detroit Plans Comprehensive Scheme For Grade Crossing Removal

City Engineers Study Problem as a Whole and Recommend Program for Next Fifteen Years — Prepare Standards of Design and Study City Planning, Freight Yards and Industry Tracks

GRADE crossing elimination at Detroit, Mich., is viewed as a single problem by a city engineering commission which has just reported. The needs of the city for the next 15 years have been carefully studied, and a progressive program has been laid out for the completion of all the necessary work in that time. Other important factors of the problem discussed are the relative advantages of full and partial elevation, the clearance and design of subways, the relation to industry facilities, the relation to streets in outlying districts of the present and future, the city-planning aspect and the apportionment of cost.



PLANS FOR GRADE CROSSING ELIMINATION AT DETROIT INCLUDE ENTIRE CITY

The report was made by the city's Division of Grade Separation and Bridges, under the direction of the Department of Public Works. This division was established in January, 1917, with John W. Reid as engineer in charge and Prof. Henry E. Riggs, of the University of Michigan, as consulting engineer. Its report was submitted in September to Clarence W. Hubbell, city engineer, and passed with his approval to H. H. Esselstyn, commissioner of public works, who in turn transmitted it to the city council. It was referred to the council committee on grade separation and it is expected that early action will be taken by the new council.

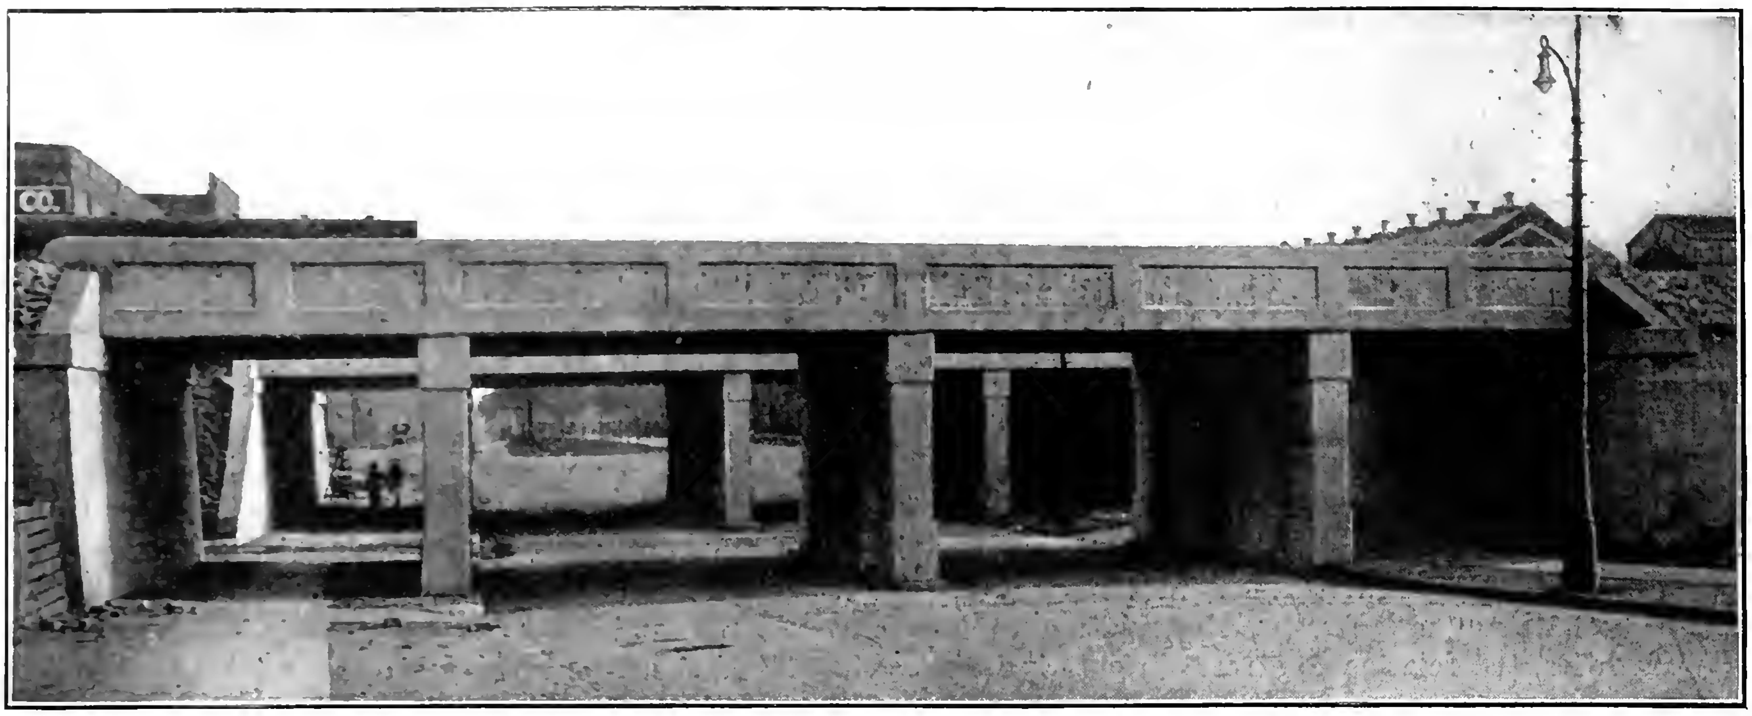
Modern grade-crossing elimination in Detroit dates from 1900, and in 1903 an agreement was made by which the annual expenditure was to be not over $200,000. This was amended slightly in 1906, and additional agreements were made up to 1917. Work which was to have been commenced by the New York Central Railroad and the Wabash Railroad in 1917 was deferred owing to war conditions, by permission of the city council. Since 1900 there have been 43 grade crossings eliminated.

Present conditions are as follows: On 64½ miles of line, considering parallel railways as one line, there are 289 street crossings, at 58 of which the grades are separated, 43 having the tracks carried over and 15 having them under the streets, while 20 more crossings are covered by existing contracts. There remain 211 grade crossings on main lines and 34 on industrial spurs, while 37 of the former carry street-car tracks. Counts made at 147 crossings in 1917 showed an average traffic of 1011 street vehicles and 41 train movements per crossing per day. Street-car movements over crossings were about 250,000 for the year, or probably more than 1,000,000 movements over tracks. Grade separation demands attention urgently as a part of the city's traffic problem. It appears that with the growth of the city the increase in number of grade crossings has been greater than the decrease by grade separation.

Early completion of plans for a comprehensive scheme of eliminating grade crossings, together with a definite program of construction, is recommended by the report. No such program has been prepared, as yet, but the railway system of the city has been divided into sections which may be handled successively. Determination of the grades of streets and railways will permit the making of provision for these ultimate grades in the design and construction of new buildings and industries. With a complete scheme for the entire city the streets of heaviest traffic may be handled first and work carried on at different points and on different properties at the same time, so that no railway will be unduly burdened in any one year.

A program of work must take into account the fact that as it progresses the city will increase in population and area, and that there will be an increase in miles of railway and number of streets. Such a program, it is explained, would cover all railways within the city limits, all existing crossings and all additional crossings which may be necessary to furnish traffic connections with new industrial or residential sections of the city.

The cost of work to be provided for by a comprehensive plan is estimated at from $30,000,000 to $50,000,000. For the completion of such work by 1935 or 1940 the annual expenditure must be very much larger than the limit of $200,000 provided in existing contracts with the railways. To carry out the program it is recommended that the contracts should fix an annual amount, increasing with each year, so as to place the heavier share of the burden on the later years of the period. It is suggested that $2,000,000 for the first year is the minimum to be considered in view of the work urgently needed, and that this should increase about $200,000 per year until it reaches $4,000,000 in 11 or 12 years.



CONCRETE SUBWAY ON DETROIT TRACK ELEVATION: SECOND AVENUE AT NEW YORK CENTRAL LINES AND GRAND TRUNK RAILWAY

Street 80 feet wide has two 21-foot roadways, 13-foot headway and 3—18 per cent. grades

Elevation of tracks as the main principle, in combination with depression of streets as a secondary consideration, is the method advocated in the report. All the work done so far at Detroit has been based on the compromise system of elevating tracks from 6 to 10 ft. and lowering streets from 6 to 14 ft., the comparatively slight elevation being due largely to the fear of owners of industries that a greater elevation would harm them seriously. Another reason, probably, was the belief that greater elevation would lead to excessive cost, but the report states that the total cost is no more for 15 to 17 ft. than for 6 to 8 ft. elevation. Adjustment of tracks in industrial plants may be more expensive, but can usually be made without difficulty, and in close quarters the loading and unloading may be handled at platforms on the second-floor level.

Public interest must dominate in fixing grades of the main traffic streets, since this interest is so overwhelmingly large. For these reasons the following recommendations are made in the report: On all main arteries the maximum street depression should not exceed 2 to 3 ft., with approach grades not exceeding 2½%; on other important streets the maximum street depression should be 5 ft. and grades 3%; in purely industrial districts, especially where the streets carry little through traffic, considerably greater depression may be permitted, but in no case should the grades exceed 3½ to 4 per cent.

Track elevation is shown to be the logical method of eliminating grade crossings at Detroit, since the flat topography, as at Chicago, would prohibit depression on some lines, while complications from sewers and water mains would either prevent it or make it expensive on most lines. For clearance at subways 14 ft. has been adopted in the past at Detroit, but 15 ft. is provided for on some work, and this figure is recommended for streets that have or are likely to have street-railway line. For streets without car lines a clearance of 13 or 14 ft. is considered ample.

Track depression is recommended, however, for that part of the Grand Trunk Railroad on De Quindre St. from Jefferson Ave. to Hale St., 1.3 miles, beyond which there would be track elevation to Clay Ave., two miles. It is explained that this case is exceptional. While the tracks are now on the street level they already pass under three important streets, no large industries are served and there are no complications due to sewers or other underground utilities, as the road was built some 60 years ago. The railway has proposed elevation of its tracks for the entire distance and has submitted two projects, but the report considers one of these open to strong objections, and both of them inferior to track depression on the first section of the line, so far as public interest is concerned. This matter is now awaiting the decision of the Michigan State Railway Commission.

Taking up the design of subways, the report advocates concrete structures, properly waterproofed and having ballasted floors, and the flat-slab type is preferred to arch designs. It is pointed out that extra expense for appearance should be avoided in view of the great total cost and the large number of structures, although some expenditure for this purpose may be warranted at structures crossing boulevards and main thoroughfares. It is recommended that no intermediate supports be permitted in streets of widths up to 50 ft. Where the width is greater or the crossing is at an angle, supports at the curb lines may be necessary to avoid excessive height of elevation, but a support in the middle of the street should not be considered when the width between curbs is less than 60 ft. Shorter spans may be permissible for driveways and streets serving industries only.

An adequate city plan of streets and roads should be made in advance of agreements for grade-separation work, and the report suggests that the city plan commission should coöperate in this respect. Proposed changes in streets should be considered in their relation to grade-crossing elimination, and it is recommended that in general long through streets should be maintained at full width. Opening of new streets and widening of existing streets should be considered as part of the grade-separation project when traffic can be improved in such ways. Closing of streets, it is suggested,

should be considered only in order to improve a subway approach or where the streets are very short or very near the river, where traffic will always be limited. In industrial districts, however, the closing or changing of streets may be of benefit to the railways, the city and the industries.

Location of large railway yards in the outlying districts is a special condition noted, as in some of these cases opened streets are several thousand feet apart, and subsequent plotting of lands adjacent to the right-of-way has been made without reference to the possible opening of streets across the railway. The report urges a careful study of railway right-of-way within the city limits, and the location of a sufficient number of cross streets connecting with main thoroughfares. These should be of ample width, 66 ft. country roads being opened at least across the right-of-way for future avenues of 80 to 100 ft. width. Plans for grade separation on these outlying thoroughfares, it is pointed out, should not be made without full consideration of their future effect upon the city.

The effect of grade separation on industries is discussed as an important consideration. At 880 industries there are 1600 private sidings with a capacity of 15,635 cars, while 159 industries which are located on the railways use team tracks instead of private sidings.

Some industries—large and small—will not be affected seriously, while others will be subjected to considerable trouble and expense. In general, however, track elevation to approximately full height is the cheapest method for the railroad and also brings the tracks near to second-story factory levels, so as to involve less change and reconstruction and to give better spur track grades than an elevation of only 6 to 8 ft. Furthermore, many industries such as coal yards and warehouses can handle a larger volume of business with tracks at the higher level.

Relative Cost and Its Apportionment

Cost of track elevation, says the report, is largely in grading and masonry, and in carrying traffic during construction. For a railway fill made by trains, the cost of steam-shovel loading, train haul and unloading will average less than half the cost per cubic yard of removing the clay soil in Detroit streets, hauling it by wagon to scows and then dumping. Masonry walls for such a fill are of uniform height and standard section, while street retaining walls having approximately 10% more material are irregular in height and section and consequently of greater cost per cubic yard. The cost of permanent bridges and that of carrying railway traffic during construction are substantially the same in either case, while the cost of carrying street traffic during construction is said to be less with railway elevation than with street depression. The cost of track construction and readjustment of industry tracks for elevation is considered to be more than offset in track depression by the cost of rebuilding sewers, water mains, paving, sidewalks and street-railway tracks, in addition to the property damages.

Full elevation of the railway, without change of street grades, is the cheaper solution of the problem, according to the study made at Detroit. The report states that this holds fairly true for all railway right-of-way of 60 to 100 ft. width, with eight or nine streets per mile. It will not hold true, however, where there are only a few streets per mile and where the railways have large yards, nor where the elevation of the railroad involves that of a large mileage of industrial spur tracks or extensive rearrangement of numerous factory buildings.

The apportionment of the cost of grade separation at Detroit has been usually on the basis that the railways

STEEL SUBWAY ON DETROIT TRACK ELEVATION; WABASH AVENUE AT NEW YORK CENTRAL LINES AND GRAND TRUNK RAILWAY

Street 65 feet wide has 26-foot roadway, 13-foot headway and three per cent. grades

have paid the entire cost of construction on their land and on the streets, while the city has paid all property damages, and the street railway has paid for all temporary work needed to maintain its traffic and for all new track and overhead equipment. No adequate or uniform records of cost have been kept, but it is generally understood that the city's share has been 20 to 25% of the total cost. The report considers it probable that with greater elevation of tracks the cost of property damages will be reduced, thus decreasing the city's share of the total. It is considered reasonable, however, that the city should pay from 20 to 25% of the cost of a well designed public improvement and should assume the entire maintenance of the streets. On the other hand, the report points out, the new city charter appears to contemplate payment of nothing more than property damages, so that any plan imposing upon the city a definite percentage of cost probably would have to be passed upon by the courts. As to street railways, the report considers that the company should build its own tracks and pay more than its past share of 2 to 3% of the total cost. Municipal utilities should pay for changing their underground properties to conform to the street changes.

Road Funds Available in Wisconsin

For construction and maintenance on the Wisconsin trunk-highway system and the county systems of prospective state highways, about $11,000,000 will be available for 1919, according to the estimate of A. R. Hirst, state highway engineer. This includes $3,800,000 for state-aid construction, $3,200,000 for Federal-aid construction, $1,500,000 for county construction and $2,500,000 for state and county maintenance work. In addition, the towns will spend about $3,000,000 on township roads.

Governors' and Mayors' Reconstruction Conference Fails to Get Action

Officials at Meeting in Washington Do More Listening Than Talking and Adopt Prepared Resolutions, but Recommend No Comprehensive Program

(Editorial Correspondence)

TWENTY GOVERNORS, 135 mayors, and the representatives of many more executives, met at the White House last week at the invitation of the President to discuss the problems of unemployment and business resumption. They listened to many set addresses by Federal officials, told one another generally of the conditions in their home communities, received a vague program of action from the representative of the Department of Labor, passed reluctantly a wordy and innocuous document prepared for them by a committee on resolutions, and broke up in disorder with an evident feeling of the futility of the conference. Possibly some of the delegates got a thought or two from the discussions which they may put to use when they get home, but no definite, beneficial suggestions materialized on the floor.

The conference was called by the President at the request of the Department of Labor, and was apparently planned and directed entirely by that department. In the light of the proceedings of the three days, it is now very apparent that there was too much direction. A full program was laid out, made up of addresses by men of such national distinction as to make it impossible for the floor to do other than to hear them. These gentlemen all delivered inspiring and stirring addresses, but it soon was evident that the Governors possibly, and the mayors certainly, had come to Washington not to listen but to talk, and the program did not permit such talk. As an ending to the conference, the mayors got together in a more or less informal organization for future meetings, in the hope of establishing something similar to the present House of Governors.

What the Meeting Was For

According to the President's own announcement, the meeting was "to discuss the proper method of restoring all the labor conditions of the country to a normal basis as soon as possible and to effect any such fresh allocations of labor and endeavor as the circumstances may make necessary." This was the extent of the President's reference to the conference itself. His mind, as evidenced in all of his addresses in this country during his brief stay, was on the matters of international relations, which he soon reached in his speech to the conference. He was followed by Secretary of Labor Wilson, who in a remarkable address clearly indicated the serious possibilities in the labor situation in this country and the decided necessity for immediate resumption of business. Then, after brief addresses by the Secretaries of War and the Navy, the Governors of the various states were called on alphabetically. Here the conference met a surprise, because, with only two exceptions, every Governor arose and stated that there were no labor or industrial troubles in his state. Arizona admitted some difficulties in the copper-mining districts and West Virginia in the coal-mining.

The best part of two sessions was taken up by the Governors' speeches, some of which were direct and to the point. Confidence in conditions, however, was soon shattered when the mayors were given the floor. Unfortunately, the program was so full that only a few of the mayors could be heard. Those who did speak, however, definitely stated that the Governors did not know what they were talking about, that labor and industrial conditions were bad, and that there was no immediate indication of relief.

Through all of the reports there was no sign of any great revival of public work. Here and there an executive announced that his state or city was going ahead with a certain amount of work, in general very much less than normal, but many of them repeated the same statement; that is, that so long as material prices kept up not even a public body could be expected to engage in work. Several of them, Governor Cox of Ohio in particular, definitely demanded that the water be squeezed out of present material prices.

The Plan of the Labor Department

Meantime, a representative of the Department of Labor announced what he called not the plan, but the suggestion, of the department as to a program of reconstruction. He laid down seven items in this program: First, begin all public work, especially public buildings and schoolhouses; second, get behind the Build-a-Home movement; third, get the state to build its full quota of Federal roads on the fifty-fifty basis and appropriate large sums for state roads; fourth, see that traction properties of the state and city receive fair treatment; fifth, urge labor to give a greater service for its wage; sixth, get the state councils of defense to advertise as much now to get people to buy as they advertised during the war to get people to economize; and seventh, help the cabinet officers in their efforts to extend opportunities and provide not only employment but a strong United States Employment Service.

Following more addresses, one on building by a representative of the construction industries and one on roads by a representative of the highway industries, and one by Secretary Lane on his various reconstruction policies, the Resolutions Committee, composed of Governor Cox of Ohio, as chairman, and Governors Sproul of Pennsylvania, Bilbo of Mississippi, and G. F. Peabody, representing Governor Smith of New York, together with Mayor Peters of Boston and Mayor Baker of Portland, Ore., brought in the report of the committee on resolutions. Contrary to the expectations of most of those in attendance who had hoped for a series of definite resolutions which could be voted upon one by one, this document was a well prepared essay of the type common to party platforms, and was so tied together as to make it impossible of paragraph acceptance. It was read with considerable oratorical effect by Governor Cox, and was accepted, after a great deal of opposition, by a two to one vote of those present. Only one clause

was added, recommending to the states that they consider means of releasing natural resources from controllers who, for the purpose of speculation, are holding them. There was also a squabble over the public utilities clause noted below, but that was finally adopted by another two to one vote.

Abstract of the Resolutions

The committee's report, which was supposed to embody the findings of the conference, starts with well-rounded phrases, such as, "We are living in the most thrilling time in all history," "We must progress from the fundamental base of American ideals," "The principles of government must change through the evolutions and processes of calm human intelligence," etc., etc. It has clauses condemning any doctrine which inveighs against both God and government. While admitting that it was not the purpose of the conference to discuss the underlying principles of the question of government ownership, it recommends that the national Government in its present conduct of the railways should continue in the purchase of rolling stock, making added betterments, etc., so as to guarantee at least that much of the purchasing of material which should be started at once. It recommends that the Government make a careful analysis of all economic elements underlying costs, and that it establish a fair price for materials, which price is to be followed by the Government itself, with the idea that if the Government in fairness to all interests concerned approves price schedules on materials, public opinion will accomplish the rest in the needed reduction of prices. Indeed, the one definite part in the resolution is, "Prices must change. There may be an economic justifition for some schedules but not many, and if the Government through the operation of a committee or commission such as we have suggested will invite industry to go forward in the work before us, revealing facts and figures upon which earnest calculation can be made, it can, then, in any given line announce to the public what prices it finds to be fair and equitable."

The resolution then definitely recommends that freight rates on all road material, possibly on all building material, be radically reduced. It recommends that there be no present anticipation of an adjustment in the wage scale. It recommends "that the Federal Government continue its helpful offices, with the view to averting serious consequences in the financial affairs of public utilities." It urges that the informal contract act be put in effect as soon as possible and that announcement be made equally soon as to the disposal of Government surplus materials. It regards the discontinuance of Federal aid and maintenance of public employment agencies as both untimely and harmful, and, finally, urges a change in the method of military demobilization by which the soldiers are turned loose in the vast districts from which they came.

Some definite conclusions can be drawn from this conference. First, there is as yet no general unemployment distress, although there is certainly unemployment, growing, as the mayors recognize, but not yet to such a stage as to have come to the attention of the Governors. There is a wide appreciation of the soundness of the build-now policy of public work, but there is an equally wide distribution of the reluctance to start, on account of high prices. There is no indication of a general going ahead in public or private building in spite of the high prices existing. There is a general demand that the railroads, which it was stated many times purchased 30% of all materials bought in the United States, start buying immediately, though, as Director General Hines told the conference, the failure to provide funds by the late Congress complicates the financial situation of the Railroad Administration to a point where it can promise nothing. There is a demand that freight rates on building materials be lowered, and lowered immediately. To this Director Hines promised his immediate attention. There is an appreciation of what is generally called the Bolshevik menace, but a confidence in the American people and its ability to meet it. There is a pronounced expectation of lowering in prices and no hope of a lowering in wages.

These are the impressions derived from the conference of representative men from all parts of the United States. That men holding pretty generally the same views could not get together and coördinate those views and specify remedies or expected remedies is undoubtedly due to the failure of the Department of Labor to provide the proper mechanism for the conference. These men came from all over the country with very little idea of what they were expected to do. They were made to put in three days listening to a number of things which they already knew, and were at the end hurried to a conclusion by lack of time. The resolutions prepared by some of the shrewdest politicians in the United States, and presented on the floor by a master of debate and oratory, were carefully calculated to avoid any controversial subject or to set down in good, round terms any definite program of action. Because the resolutions were adopted there should not be the impression abroad that they represent the feelings of the floor. Those who had hoped that the gathering together of so many men intimate with local conditions would develop a national policy of reconstruction must be disappointed.

F. C. W.

Guatemala Rebuilds After Earthquakes

That reinforced-concrete is the only safe type of construction for earthquake countries has been proved by the earthquakes of Guatemala and Salvador, in the opinion of Lee F. Whitbeck, chief engineer of the International Rys. of Central America. He points out that unfortunately this type of construction is expensive in these countries, as all materials have to be imported.

Reconstruction of the buildings of Guatemala City, the capital of Guatemala, after the earthquakes of December and January, 1917-18, is making slow progress, according to Mr. Whitbeck. This condition is due to scarcity of labor and materials, and apparently to a great lack of confidence on the part of property owners, as a result of the continuance of slight quakes. This fear is evidenced by a reluctance to start rebuilding and by the false economies that are being attempted in the work. The tendency is to adopt the cheapest possible method, and if there is any chance of patching a shattered wall, this is done usually, in preference to tearing down and rebuilding.

Reinforced-mud or "bajareque" is a common type of construction, which consists of a wood frame covered with lath, the wall space being then filled with mud and plastered. The effects that an artistic plasterer can obtain are said to be both surprising and deceiving.

Pennsylvania Has Emergency Public Works Commission

Body Provided For Two Years Ago To Tide Over Expected Periods of Depression Is Now Stimulating Construction

PENNSYLVANIA was particularly forehanded in providing against a possible industrial depression which might follow the war. By an act of the legislature, July 25, 1917, it established the Emergency Public Works Commission, "to provide for the expansion of the public works of the commonwealth during periods of extraordinary unemployment caused by temporary industrial depression." While the commission has not as yet done anything other than to stimulate various kinds of public work by the cities and counties of the state, it has a well considered program which, it is hoped, will help to ward off any actual depression in the next few months.

The act provides an emergency public-works fund, starting at $50,000 in the first appropriation, and constitutes a commission composed of the Governor, the auditor general, the state treasurer, and the commissioner of labor and industry of the state. The Department of Labor and Industry has the duty of ascertaining the existence of periods of extraordinary unemployment within the state and of notifying the commission. Then it is the duty of the commission to proceed to ascertain and obtain, from various departments, bureaus, boards and commissions, tentative plans for such expansion of the public works of the state as shall be best adapted to supply increased opportunities for advantageous public labor during periods of temporary unemployment. The industrial branch of the Department of Labor and Industry is also ordered, under the same act, to conduct an employment bureau for the use of the state departments which are engaged in such public work as the emergency calls for. When an industrial depression period does not exist the emergency public works fund is to be distributed among the various departments of the state, for such expansion of public works as are best adapted to advance public interests by providing the maximum of employment for the relief of existing conditions of extraordinary unemployment.

In November, 1918, a few days after the armistice was signed, the commission began to stimulate the public works of the cities and counties of the state through correspondence. Soon after, the commission requested the various departments of the state Government to report what useful necessary public work they could do during the demobilization period, provided the necessary appropriation and organization were forthcoming. Upon receiving this information, the commission made a report to the present legislature on the method of expanding public works in the state in the existing emergency. This report is now before the legislature for action.

The report takes up in order highways, forestry, factories, and public works in cities and counties. Under highways it recommends that the legislature should assign a percentage of the usual highway appropriation directly to the emergency public works fund, for emergency expenditure only during periods of unemployment, and that a percentage of all state bonds issued for highway construction should be held out of the market and sold only when a period of unemployment occurs, in order that the work may be done at that time. Emphasis is laid on the fact that the demobilization and transition period—from April to October, 1919—should be regarded as a possible period of temporary unemployment, and highway work concentrated then if necessary.

Under forestry, the report notes that the department of forestry of the state is contemplating certain forest work that could well be carried on at the present time, with the employment of 5000 unskilled laborers for three months. It is also noted that the water supply commission is prepared to undertake public works and stream conservation and flood control if a million-dollar appropriation is made. The investigations of this department are quite necessary for the continuance of a number of other public works.

The department of health has possibilities as an employer of labor at the present time, both in the construction of certain necessary sanitariums and in the work in destroying the mosquito. Notice is also made of the fact that for some years past the department of health has ordered certain boroughs to put in sewage-disposal plants, in order to relieve a menace to the public health. Some of these boroughs have not complied with the order, the reason given being that they have reached their debt limit. The report says that the question arises whether a part of the emergency public works fund could not be let to such boroughs in order that they may comply with the health department orders and also provide necessary public work at this time.

Certain taxes, notably the inheritance tax, could well be diverted toward the public works fund, according to the report. At any rate, the whole question of taxation in relation to this kind of work needs to be investigated. Finally, the report to the legislature emphasizes the publicity work that the commission can do in urging the minor political subdivisions of the state to enter into construction work at the present critical time.

The office of the commission is at the capitol at Harrisburg, and Otto T. Mallery is acting as executive secretary.

Standardizing Concrete Pipe

That design of concrete pipe should be standardized to the extent of adopting a certain range of diameters and five classes of varying strength, was the suggestion made in a paper read at the annual meeting of the American Concrete Pipe Association by C. F. Buente, of the Concrete Products Co., Pittsburgh, Penn. Length of pipe and type of joint are matters that, he thought, should be left to the judgment of the manufacturer. To obtain pipe of high quality and strength, he advocated the use of concrete made with a low proportion of water, but he did not know whether such concrete had been used for reinforced-concrete pipe. The meeting was held at Chicago Feb. 14-15. Officers of the association were elected as follows; President, W. E. Goodman, Saginaw, Mich.; secretary, G. E. Warren, Universal Portland Cement Co., Chicago.

Old-Fashioned Methods Reduce Cost of Dam Repairs

Contractor Met Local Conditions and Avoided Expensive Operations Without Interrupting City's Water Supply

By Charles F. Dingman
Assoc. M. Am. Soc. C. E., Engineer, Flynt Building & Construction Co., Palmer, Mass., and New York City

TEN thousand dollars was appropriated by the City of Willimantic, Conn., to preserve the dam in the Natchaug River on which the water-supply and fire protection of the city depended. The contract was awarded for $7000 and the contractor, by the application of old-fashioned but economical methods that conformed to local conditions did the work for less than $4000, although estimates ran up to $39,000.

The dam is about three miles from the city and is of heavy stone-masonry construction, built in 1884. It provides a head of 21 feet, which is utilized to drive two Hunt-Smith hydraulic turbines, operating in turn two Worthington plunger-type pumps. These work at a normal speed of 80 strokes per minute and pump the water through a 12-in. cast-iron main to the reservoir near the city. A steam pumping plant has been provided for auxiliary purposes, but the expense of getting coal to the pumping station makes it necessary to use the auxiliary pumps only for emergency.

VIEW OF DOWNSTREAM SIDE OF DAM, TAKEN FROM SOUTH BANK

For some time past it had been noticed that the front, or downstream, face of the dam showed an appreciable bulge, extending for somewhat over 100 ft. of its total length of 280 ft. During the past summer this bulge reached such proportions as to cause fears for the safety of the entire structure, and an appropriation of $10,000 was obtained to defray the cost of repairs.

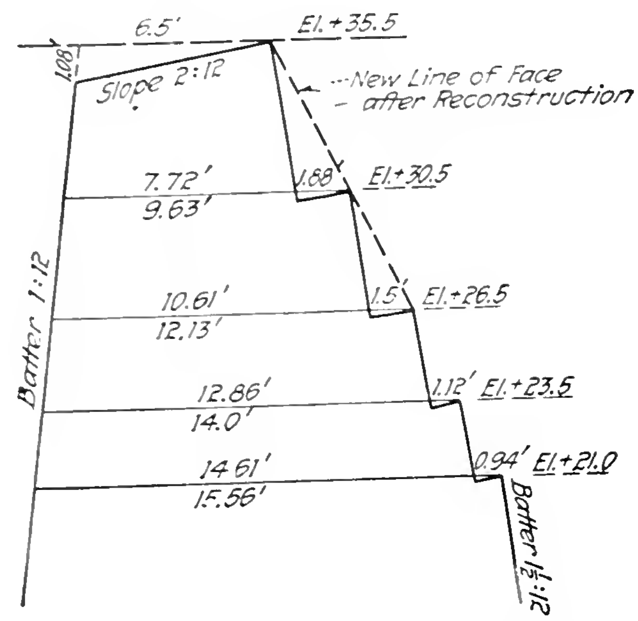
Water overtops the dam during a great part of the season, and, owing to the fact that the waste gates had not been opened for over a quarter of a century, some doubt was entertained as to the possibility of opening them at all so that the water could be drawn down to a point which would permit repairs without the use of expensive cofferdams and other temporary work. Doubts were increased when a diver found the stems of the two iron gates badly corroded and likely to twist off at the first attempt to turn them. The iron gates are 3 x 3 ft., and similar in design to modern sluice gates. In addition two wooden waste gates were provided. The stems of these, however, do not come up to the top of the dam.

The work of lowering the water apparently presented the greatest problem in the entire operation, and until this was done no inspection or plans could be made. The superintendent placed in charge of the work avoided the use of a diver in opening the gates by slinging a chain around the stem of one of the wooden gates, drawing it up and opening it. One of the iron gates was opened by making a new socket wrench sufficiently large to engage the end of the stem, and operating it in the usual manner. There was then some doubt of closing them again, but it was done without difficulty.

As soon as the water was drawn down below the top course of stone the coping was removed, and a large crevice was found. This crevice extended down for 10 or 15 ft. into the body of the dam, and was entirely filled with disintegrated mortar, decayed vegetation, etc. The crevice was undoubtedly caused by the action of water which found its way into the joints of the stone work, the successive freezing each winter causing it to become larger and larger. Although the masonry in the dam is composed entirely of large and heavy stones, there was no bonding between the face and the body of the dam, thus accounting for the facility of the frost action. This made it possible, however, to leave the rear or upstream portion of the dam in place while the front of the dam was removed. The profile of the dam, shown on the sketch (see next page), made it entirely feasible to do this, there being sufficient bulk remaining to make the use of a cofferdam unnecessary.

After the coping and front stone were removed and the disintegrated mortar, decayed vegetation and other

CONDITION OF DAM EXPOSED ON REMOVING COPING, AND SHOWING CRACK



CROSS-SECTION OF THE DAM

foreign matter were thoroughly cleaned out, the joints, wherever possible, were filled with grout, and the face was rebuilt to the new profile, shown in dotted lines on the diagram. The coping was then reset in cement mortar.

The stone was handled bv a hand derrick, as shown in the photograph; this was the interesting feature of the work. Many who saw the work thought this method old-fashioned and inefficient, but it was adopted after much thought had been given to the relative cost of a steam and a hand derrick. The cost of moving a boiler and engine to the work, setting it in place, removing it, and returning it to the equipment yard would have greatly offset the probable cost of all the labor of operating the derrick by hand, and it would not have been possible to raise the stones in sufficiently rapid succession to pay for the higher cost of having an engineer constantly on duty. It is particularly difficult to get coal in this locality.

The various estimates for the cost of rebuilding the dam ranged as high as $39,000, this, of course, including the cost of building a cofferdam and other temporary structures. The Flynt Building and Construction Co., which obtained the contract, estimated the work at approximately $7000, with the stipulation that it be allowed to use its own judgment as to methods. The entire work was handled for a sum considerably less than $4000, and at no time was the water-supply interfered with in any way, nor was it necessary to use the emergency steam pumping system to maintain a sufficient pressure for the water-supply.

The City of Willimantic was represented in the operation by Charles A. Gates, mayor, Henderson S. Moulton, superintendent of water-works, R. E. Mitchell, city engineer, and William A. King, corporation counsel. The Flynt Building organization, which did the work, was represented by L. H. Bogue, general superintendent, and Nelson M. Baldwin, division superintendent.

Concrete Sewer-Pipe Specifications Adopted by Los Angeles

Draft of 1919 Provides for One-to-Three Mix—Dimension Variations Fixed — Imperfections That Will Cause Rejections

Los Angeles in the spring of 1918 adopted pipe specifications for sanitary sewers whereby concrete pipe (called "cement pipe" in the specifications) might be used in place of clay pipe. The use of cement pipe caused a material lowering in the price of clay pipe. At the present time there is very little difference between the costs of the two. The latest specifications for the construction of sanitary sewers in Los Angeles were adopted by the council on Jan. 3, 1919. The main features of these specifications, as regards cement pipe, are as follows:

The cement pipe must be socket pipe of first quality, dense, tough, free from cracks. It must have a smooth interior finish and when struck with a hammer must give a metallic ring. The mixture used must not be less than one part of cement by measure to three parts of aggregate. No materials other than water, cement, sand and stone are permitted in the manufacture of the pipe. This prevents the use of waterproofing compounds. The cement and aggregate are subject to rigid inspection and test before use. The gravel or broken stone must not exceed one-half the thickness of the pipe for which it is used.

It is required that the pipe be made under cover, and the material used is machine mixed, molded and tamped. The city engineer has the right to inspect all materials, method of manufacture and finished pipe at all times. The pipe after manufacture must be kept thoroughly wet for a period of seven days, and not laid until it has cured at least 30 days. The date of making, the name of the manufacturer and the location of the plant must be stenciled on the outside of each length.

TABLE I. DIMENSIONS FOR CEMENT SEWER PIPE, LOS ANGELES, CAL.

	Thickness of Shell, In.		Depth of Socket, In.		Minimum Annular Space, In.	
Size	Standard	Deep and Wide Socket	Standard	Deep and Wide Standard	Standard	Deep and Wide Socket
6	¾	¾	2	2½	⅜	⅝
8	⅞	⅞	2¼	2¾	⅜	⅝
10	1	1	2½	2¾	⅜	⅝
12	1⅛	1⅛	2½	3	½	⅝
15	1⅜	1⅜	2¾	3	½	⅝
18	1½	1½	3	3¼	½	⅝
21	1¾	1¾	3¼	3¾	½	¾
24	2⅛	2⅛	3½	4	½	¾

Limits of Permissible Variation in Inches

Per Ft. (—)	Depth of Socket (—)	Thickness of Shell (—)	Inside Diameter of Bore, In. (+ —)
½	¼	1/16	3/16
½	¼	1/16	¼
½	¼	1/16	¼
½	¼	1/16	¼
½	¼	⅛	¼
½	¼	⅛	⅜
⅝	¼	⅛	7/16
⅝	¼	⅛	½

Note. The minus sign (—) alone indicates that the plus variation is not limited; the plus and minus sign (+ —) indicates variation in both excess and deficiency in dimension.

Pipe 30 days old must appear, when broken, homogeneous, free from voids and generally uniform; and if containing stone must show pieces of fractured stone firmly embedded in the mortar.

All pipe over 6 in. is made in 2½-ft. lengths exclusive of sockets and 6-in. pipe may be either 2 or 2½ ft. in length. The thickness of the shell, the depth of socket and the annular space are given in Table I.

The following imperfections are considered injurious and cause for rejection:

1. When the bore or socket of the pipe varies from a true circle more than 3% of its nominal diameter.
2. A pipe or special designed to be straight, exhibiting a deviation from a straight line of more than ⅜ inch.
3. A single crack in the body of the pipe extending through the entire thickness, regardless of the length of such crack.
4. A single crack which extends through one-half of the thickness and over 3 in. in length.
5. Two or more cracks in the body of the pipe of a less length than 3 in., and extending through one-half the thickness.
6. Any crack which is more than $\frac{1}{16}$ in. wide at its widest point.
7. A piece broken from the spigot end deeper than the socket or longer than one-third of the diameter of the pipe; or a piece broken from the bell if the fracture extends into the body of the pipe or is longer than one-third of the diameter of the pipe.
8. Two or more breaks in the socket or spigot, unless they can be placed in the upper half of the sewer.

The tests for cured cement pipe are the same as for clay pipe and include: (1) Sand bearing crushing test; (2) hydrostatic pressure; (3) absorption test.

Table II gives the minimum strength that samples of cement pipe must develop in order to pass the crushing and hydrostatic tests.

Sanitary sewers are constructed within specified districts, by assessment. In order that sewer contractors may know in advance what their pipe will cost them, the city engineer's office calls for bids from manufacturers of cement and clay pipe for the amount of pipe required in the district before the ordinance of intention is passed by the council. The manufacturers are required to furnish bonds and guarantee the price for one year from the date when bids are received. Residents of the district may specify whether they desire cement or clay pipe used, by obtaining the signatures of more than 50% of the property owners. **A. C. Hansen** is city engineer of Los Angeles.

TABLE II

Size, In.	Minimum Crushing Strength (Lb. per Lin.Ft.)	Fracture at Not Less Than (Lb. per Sq.In.)
6	1430	40
8	1430	35
10	1570	30

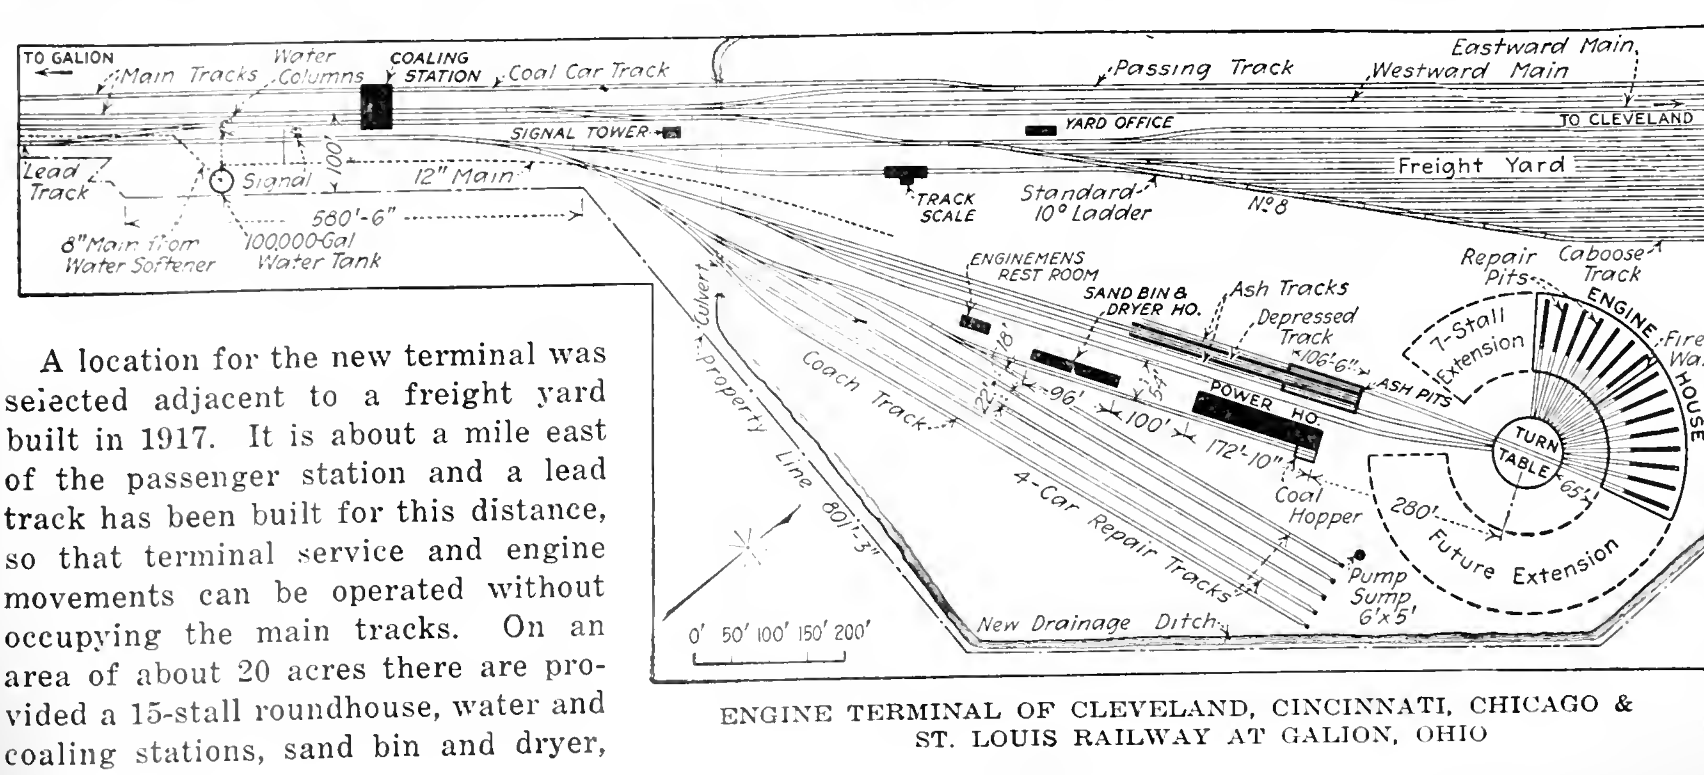
New Engine Terminal Outside City Avoids Congestion

Crowded Site Replaced by Facilities in Open Country—Water Stored and Treated—Standard Designs Employed—Engines Coaled on Three Tracks

REMOVAL of its engine terminals at Galion, Ohio, to a site in open country, beyond the city limits, has enabled the Cleveland, Cincinnati, Chicago & St. Louis Railway to design a new plant layout unhampered by existing facilities. Growth of the city around the old terminal, built in 1878, has made it impossible to extend this so as to provide the accommodation demanded by present traffic conditions, while damage by fire in 1917 necessitated hastening the construction of the new plant during 1918. About 20 engines daily have to be handled, cleaned and made ready for service, besides the train engines which take coal and water while standing on the main tracks.

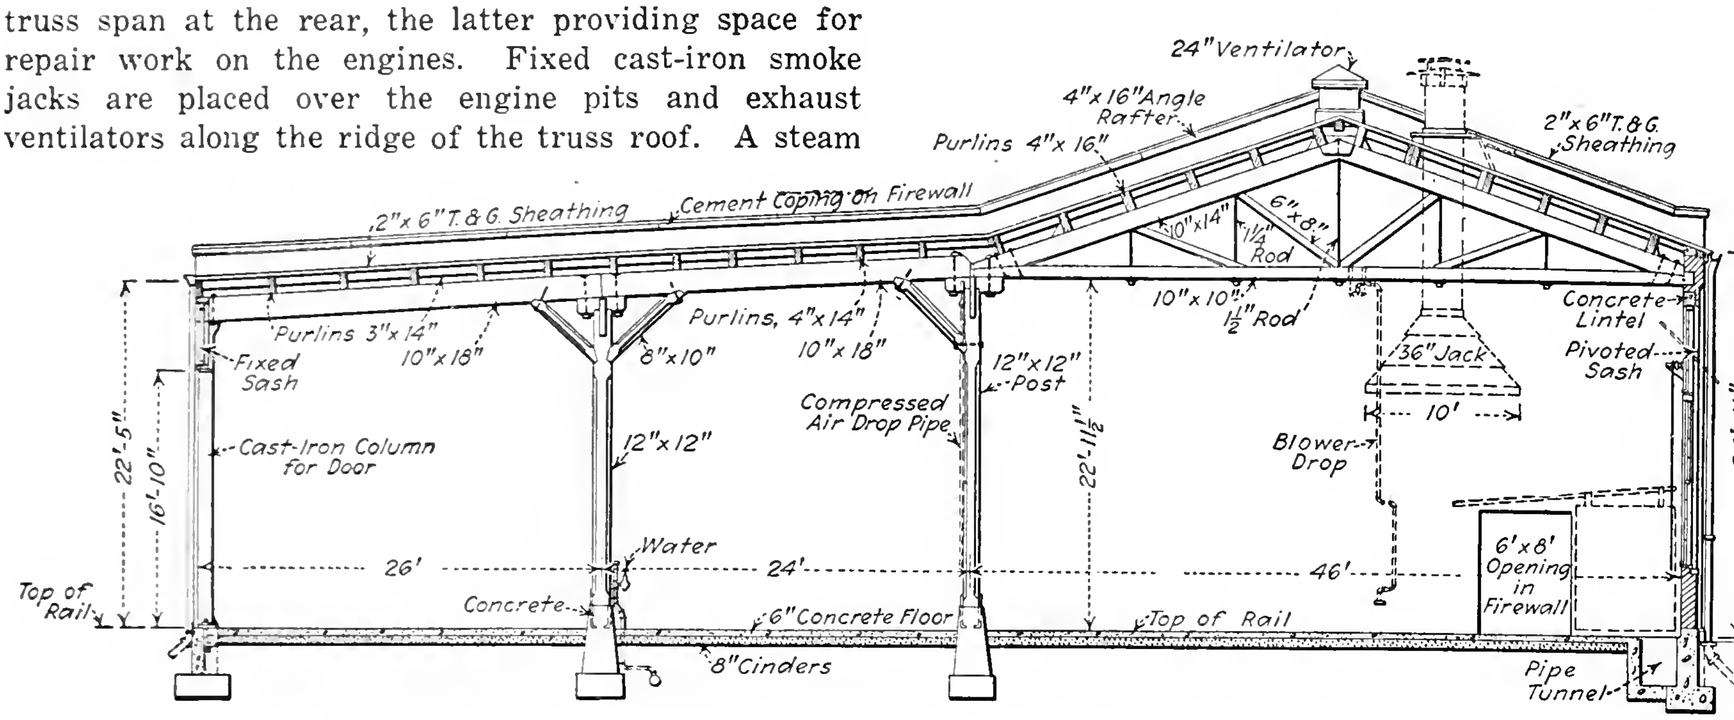


ENGINE TERMINAL OF CLEVELAND, CINCINNATI, CHICAGO & ST. LOUIS RAILWAY AT GALION, OHIO

A location for the new terminal was selected adjacent to a freight yard built in 1917. It is about a mile east of the passenger station and a lead track has been built for this distance, so that terminal service and engine movements can be operated without occupying the main tracks. On an area of about 20 acres there are provided a 15-stall roundhouse, water and coaling stations, sand bin and dryer, two cinder pits, four car repair tracks for 53 cars, a coach storage track for 10 cars, a power house with shop and storeroom, and a rest house for the enginemen. Electrically operated machine tools for light repair work are installed in an annex of the power house.

The engine-house construction follows a general building design which was adopted as standard on this road a few years ago, and which provides for brick walls and timber roof, with cast-iron columns in the front wall for the attachment of swinging doors. Lintels over the wide window spaces in the rear wall were to have been of steel, but, owing to shortage of supply, they

were made of reinforced concrete. Their span is reduced by two intermediate posts of 6-in. channels, resting on the concrete footings. A firewall divides the building into two sections. Two rows of wood posts on concrete pedestals support the roof framing, which consists of two beam spans at the front and a 46-ft. truss span at the rear, the latter providing space for repair work on the engines. Fixed cast-iron smoke jacks are placed over the engine pits and exhaust ventilators along the ridge of the truss roof. A steam pipe resting on the truss chords has vertical branches or drop pipes for use as blowers in engines which are having the fires started.



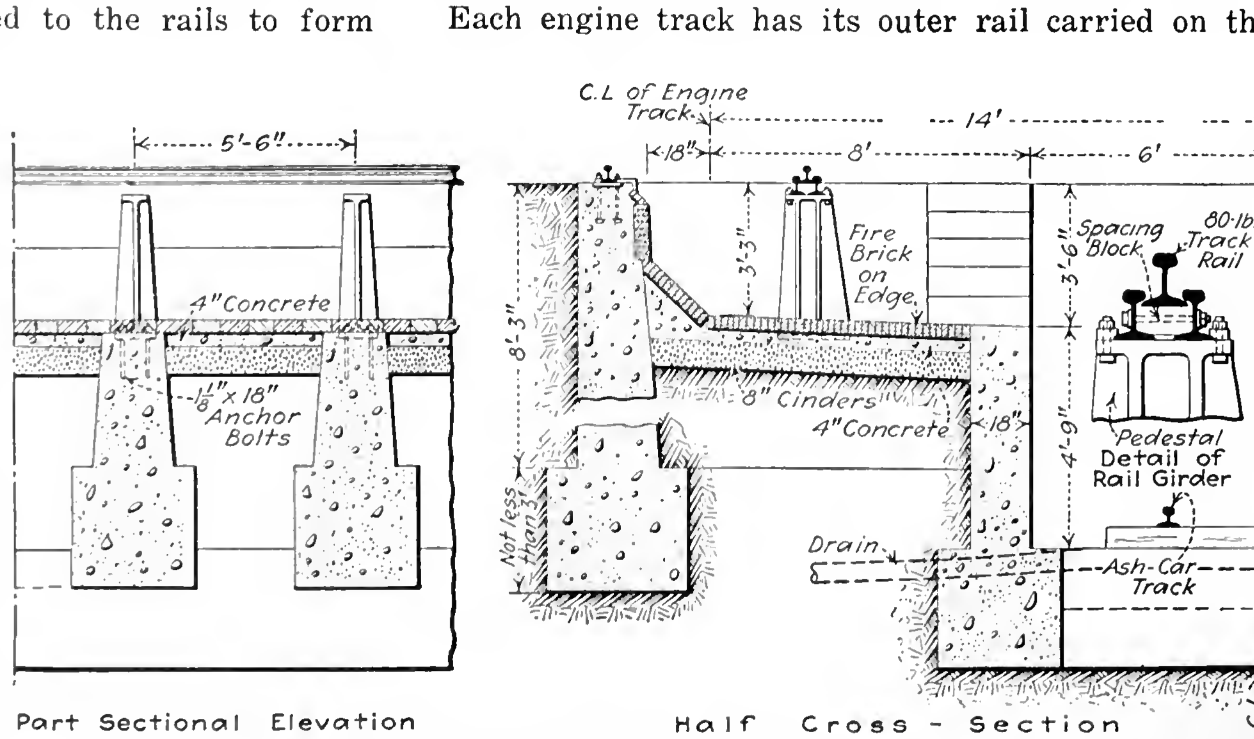
TIMBER FRAMING FOR ROUNDHOUSE ROOF, GALION, OHIO, ENGINE TERMINAL

At present the engine house is built for 15 stalls, but there is provision for a seven-stall extension. The angle between the radial tracks is 7½ degrees. Concrete pits 65 ft. long provide for inspection and repair, and have convex bottoms so that the floor will be dry for the men working under the engines. The side walls have corbeled projections on the inside to protect the water and steam pipes carried along the sides of the pit, while heavy projections on the outside provide supports for engine jacks. Track rails rest on steel plates and are fastened by clips and nuts on anchor bolts embedded in the walls of the pits. No drop pit is provided for taking out wheels and axles, the engines being raised by a jacking hoist with power-driven screw jacks to permit of such removal. The floor is of concrete, steel guards being bolted to the rails to form the flangeways. Pipes and electric cables are laid in a 3-ft. tunnel against the rear wall. In the 90-ft. center-bearing plate-girder turntable the pivot is a 20-in. flat disk with a device for securing a central bearing, this being a standard design on this road. The circular rail is laid on ¾-in. plates on a bench of the concrete wall and is secured by anchor bolts. At main entrance points, where there is impact as the entering load tilts the table, this rail is carried by a segmental 12-in. I-beam resting on short pieces of rail, all embedded in the concrete. Coupled to one corner of the table is a tractor with a 30-hp. motor driving a wheel which rides on the circular rail.

Steel bents with H-beam posts are embedded in the wall of the pit to support the ends of the tracks and thus prevent their depression due to the impact of engines passing off the turntable. There are three approach tracks, two of these being the ashpit tracks and the third a running track which permits of direct movements to and from the turntable. A 65-ft. open space extends between the roundhouse and the turntable.

Mechanical equipment is not provided for removal of ashes from the pits where the engines have their fires cleaned or dropped, the reason given being that such equipment has been found unsatisfactory in operation and expensive in maintenance. The ashpits are of the depressed-track type, 100 ft. long, with two engine tracks spaced 28 ft. on centers and having between them an ash-car track at a lower level but rising to the surface on a grade of 4 per cent. Side-dump cars are used, having A-shaped floors and being of such height that the ashes can be shoveled into them readily from the floors of the ashpits.

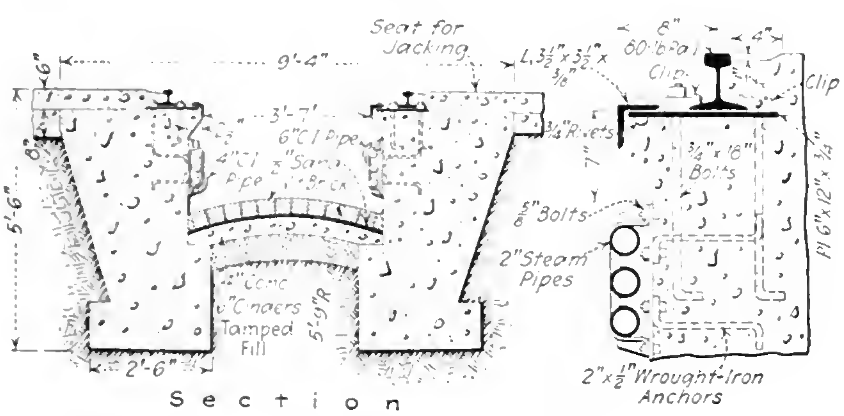
Each engine track has its outer rail carried on the



ENGINE ASHPITS HAVE DEPRESED TRACK FOR ASH CARS

side wall of the pit and its inner rail on a girder supported by cast-iron pedestals, as shown in one of the drawings. This girder consists of a pair of 80-lb. rails bolted together through spacing blocks upon which the track rail rests. Thus the heads of the former fit over the base of the latter and grip it firmly when the bolts are tightened. Spacing blocks 22 in. apart and 6 in. long are used; except that 18-in. blocks with four bolts are used under the rail joints. The track rail on the wall has the inner side of its base gripped by a continuous angle which protects the corner of the wall and is secured by anchor bolts. On the outer side the base is held by clips on similar bolts.

Water-supply for the locomotives and for the service of the terminal is taken from a small creek; a dam forms a pump pit. An electric pump delivers the water to a 17,000,000-gal. reservoir formed by an embankment across low ground alongside the creek and providing storage for low-water periods. From this the water is pumped to a water-softening plant, whence it flows to a 100,000-gal. wood tank placed at such an elevation as to give a gravity flow to a similar tank at the entrance to the engine terminal. The latter distributes a gravity supply to the buildings and to two water columns at the coaling station and two at the cinder pits. An 8-in. main connects the two tanks and a 12-in. main leads from the yard tank to the 10-in. water columns and to the buildings.

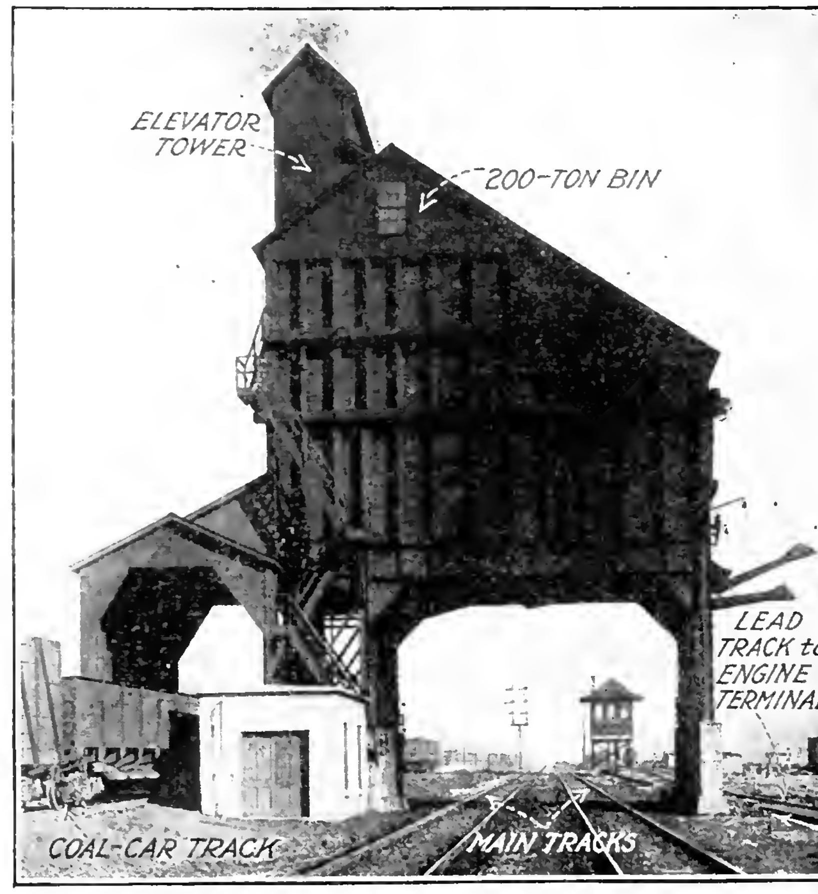


DETAILS OF ENGINE PITS

Engines on three tracks are served by the coaling station, which has a 400-ton bin spanning the two main tracks, with chutes on one side for delivery to engines on the lead track. On the other side is the coal-car track, with a receiving hopper from which the coal flows to a single 1½-ton bucket working automatically in an elevator tower. The bin is of timber and is supported by steel girders which span the tracks and are carried by steel bents, the lower portions of these being inclosed in concrete walls as a protection against blows from derailed engines and cars. Sand is screened and dried in a separate building and is delivered to the engines through pipes by compressed air.

In the power house are two 200-hp. marine boilers and a compressor. This plant furnishes steam for heating and for the engine-house blowers, compressed air for operating tools and testing brakes, and hot water for washing out the engine boilers.

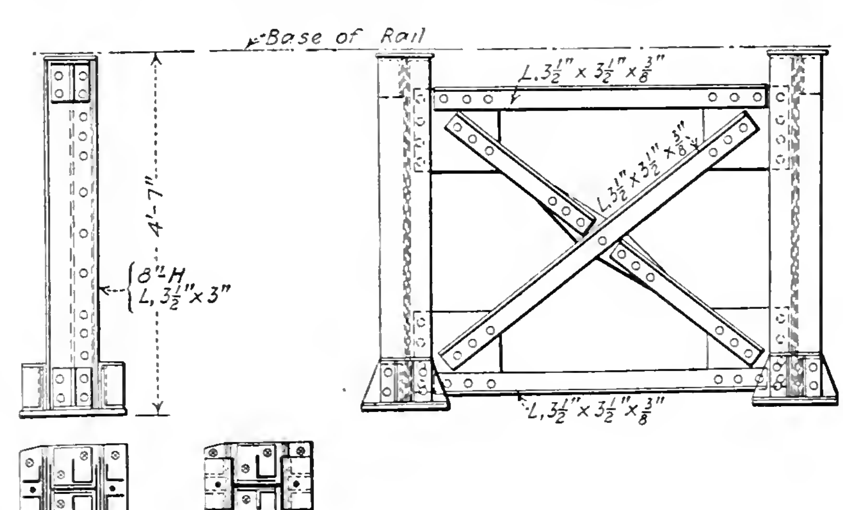
Some grading was required to prepare the site, and a drainage ditch crossing it was replaced by a ditch excavated along the boundary line and carried under the tracks in a 36-in. sectional cast-iron culvert. Drainage and sewage from the buildings, yard, turntable pit



COALING STATION SERVES MAIN TRACKS AND LEAD TRACK TO TERMINAL

and other points are carried by a system of clay pipe and concrete pipe drains to a manhole or sump, where a float-controlled electric pump raises the water about 8 ft. to an outfall pipe discharging into the ditch. The soil is a yellow clay, changing to a stiff blue clay which makes a good foundation. Piles are used only under the footing for the turntable center. Woven-wire fencing which incloses the site is carried by concrete posts designed and made by the railway.

Plans for this engine terminal plant were made under the direction of C. A. Paquette, chief engineer of the railway, and the work was in charge of W. C. Kegler, district engineer at Galion (and W. S. Burnett



STEEL BENTS IN WALL OF TURNTABLE PIT SUPPORT ENDS OF TRACKS

during the illness of Mr. Kegler), with J. Humphries as assistant engineer. The Walsh Construction Co., Davenport, Iowa, has the contract for the buildings, turntable pit and cinder pit. The coaling station was built by the Ogle Construction Co., Chicago, and the turntable by the American Bridge Co. Laying the 8-in. and 12-in. water mains from the water-softening plant to the terminal tank and water columns was done by the railway forces.

Hydraulic Efficiency of a Drainage Ditch for Five Different Channel Conditions

Photographic Views and Tabular Data for Varying Channels Show Effect of Straight and Curved and Clear and Obstructed Courses

By C. E. Ramser
Senior Drainage Engineer, United States Bureau of Public Roads

Experiments to determine the values of n in Kutter's formula

$$C = \frac{\frac{1.811}{n} + 41.66 + \frac{0.00281}{s}}{1 + \frac{n}{\sqrt{r}}\left(41.66 + \frac{0.00281}{s}\right)}$$

were made on five courses of the South Forked Deer River between Jackson and Roberts, Tenn. The channel along these courses varied from a newly dredged channel, in excellent condition, to a very crooked course of the old river channel, in very bad condition. Views of these courses of channel are shown in Figs. 1 to 5. In Tables I to V are given the values of n obtained for each of the courses for stages ranging from low to high, and a full description of the conditions existing along each of the courses.

As may be seen from the tables, the lowest values of n were obtained for the course of channel near Roberts (Fig. 1). Values of n were determined for this course from four to six months after the dredging of the channel had been completed. The low values of n obtained for this course as compared with the values for the other courses may be attributed to the comparatively smooth and regular side slopes and bottom, the uniformity of cross-section, and the freedom from growth or obstructions in the channel.

The effect of roughness and irregularities in the lower portion of the channel is revealed in the results obtained for the course near Jackson (Fig. 2 and Table II.) Although the channel was practically free from vegetation or obstructions of any sort, yet the values of n are considerably higher than those obtained for the course near Roberts. The irregularities in the lower portion of this channel were left at the time of construction, the bottom and sides of the channel never having been smoothed properly. The values of n for this course were determined from nine to 12 months after the construction of the channel.

FIVE COURSES OF THE SOUTH FORKED DEER RIVER, TENNESSEE, SHOWING DIFFERENT CHANNEL CONDITIONS

Fig. 1—Straight and uniform. Fig. 2—Straight and rather poor. Fig. 3—Straight and irregular. Fig. 4—Fairly straight but irregular. Fig. 5—Irregular and obstructed

The numbering of the views corresponds with that of the tables. Fig. 1 is a view taken near Roberts; Fig. 2, near Jackson; Figs. 3 to 5 near Campbell's levee road.

TABLE VI. RELATIVE CAPACITIES FOR THREE COURSES OF CHANNEL

Cross section area = 315.6 sq.ft.
Hydraulic radius = 5.45 ft.
Slope = 0.0003

Courses of Channel	n	c	Mean Velocity Ft. Sec.	Discharge Sec.-Ft.	Relative Capacities of Courses Per Cent.
Dredged	0.0367	56.2	2.27	715.1	100.0
Old straight	0.0619	34.8	1.40	443.5	62.1
Old crooked	0.1460	15.1	0.61	192.7	27.0

Figs. 3, 4 and 5 represent three consecutive courses of channel located near the Campbell's levee road below Jackson. The different courses of channel are a straight course of the old river channel, a very irregular and crooked course of the old river channel, and a straight course of a newly dredged channel with irregular cross-section. Gagings of the flow were made at the upper end of the course of the dredged channel, and were used in the computations of values of n for all three courses. The advantage of this practice lies in the fact that an error in discharge would not materially affect the relative values of n, so a ready comparison can be made of the hydraulic efficiency for the three courses of channel. The values of n obtained and a careful description of the three courses are given in Tables III, IV and V. The conditions found in the two courses of old river channel are typical of old channel conditions in this section of the country. The dredged course of channel is considerably more irregular in cross-section than the courses near Jackson and Roberts, shown in Figs. 1 and 2, which accounts for the higher values of n obtained.

Referring to Tables III, IV and V, it is seen that the values of n for the discharge of 715.1 sec.-ft. are 0.0367, 0.0619 and 0.146 for the dredged, old straight, and old crooked channels, respectively, and that the slope of the water surface required for this discharge was over three times as much for the old straight as for the dredged channel. In order to show the relative capacities for these three course of channel for the values of n given above, Table VI was prepared, in which the slope, the hydraulic radius, and the cross-section area of the last set of measurements in Table III were used.

The difference in the relative capacities of the old straight and the old crooked channels is not due entirely to the curves in the latter, since the accumulation of trees, logs and other drift was greater in the crooked channel. However, the difference in the condition of the two channels may be directly attributed to the presence of the curves, since there is a greater tendency for drift and obstructions to accumulate in a curved than in a straight course of channel.

Wood-Block Pavement Has Spread Two Inches

The wood-block pavement on Market St., Chattanooga, Tenn., was 70 ft. wide and has increased in width 2 in. during the three years which this pavement has been in place, according to Robert Hooke, city engineer. This expansion has been taken up, by a reduction of the expansion joint on either side of the pavement, to one-half of its original size. Mr. Hooke attributes the spreading of the pavement to the working of solid particles of grit into the spaces between the blocks at times when the pavement was fully contracted.

Day Labor Does Municipal Work at Flint, Michigan

Engineer Favors Direct Employment for Cities of Moderate Size and Contract System for Small and Large Cities

CONSTRUCTION of sewers, paving and sidewalks, and cleaning of streets, are done at Flint, Mich., by day labor under the direction of the city engineering department. Consequently, the department must have men who are capable of directing work and handling labor, but this is a difficult problem, because men thus qualified are much in demand by contractors and others. In a paper read at the annual meeting of the Michigan Engineering Society Ezra C. Shoecraft, city engineer, said that during and since 1915 all sewer and paving work have been done in this way, except a small amount of asphalt-block paving laid in 1917. Sidewalks have been built by day labor since 1912. In the past four years the work has amounted to about 83 miles of sewers, 27½ miles of paving and 54 miles of sidewalk.

Costs and results have been satisfactory, compared with those in other cities, according to Mr. Shoecraft, who also states that the work is as good as, and generally better than, that done by contract, that it is done more expeditiously, that more consideration is given to the property owners affected by the improvements, and that urgent work receives first attention.

Good equipment is largely responsible for the success of the system. The equipment is put on each separate job on a per diem basis and is entirely self supporting, including allowance for depreciation. The original cost of the plant, including small tools, was $15,000. All machines are of a class that is generally applicable; thus those which can be used only on special jobs are avoided.

The pavement plant includes two revolving steam shovels; two concrete mixers for curbs; two mixers of 14-ft. capacity for foundation work; a 10-ton roller; an eight-ton gasoline tandem roller for asphalt; an asphalt plant capable of producing material for 1500 sq.yd. of 2-in. surface in 10 hours; five asphalt wagons of 2½ yd. each; four 5-ton dump trucks; six dump wagons; a two-ton truck; a wagon loader; an auto crane, and a dragline excavator at the gravel pit. For sewer construction there are two trench excavators for 5 x 20 and 3 x 15-ft. trenches; a backfiller; a trestle and bucket machine for large sewers, and two 600-gal. trench pumps. For sidewalk work there are eight wheeled scrapers and two concrete mixers.

Street cleaning was turned over to the engineering department about July, 1917. The equipment includes two power-operated flushers with 1200- and 1800-gal. tanks. The annual cost of street cleaning and snow removal approximates 4c. per square yard. Mr. Shoecraft believes that still greater efficiency may be secured and that the ideal street-cleaning machine has not been invented.

The day-labor system is not recommended for small cities, Mr. Shoecraft says, as it would be too expensive for them to maintain a trained force for their relatively small needs. Flint has about 90,000 inhabitants.

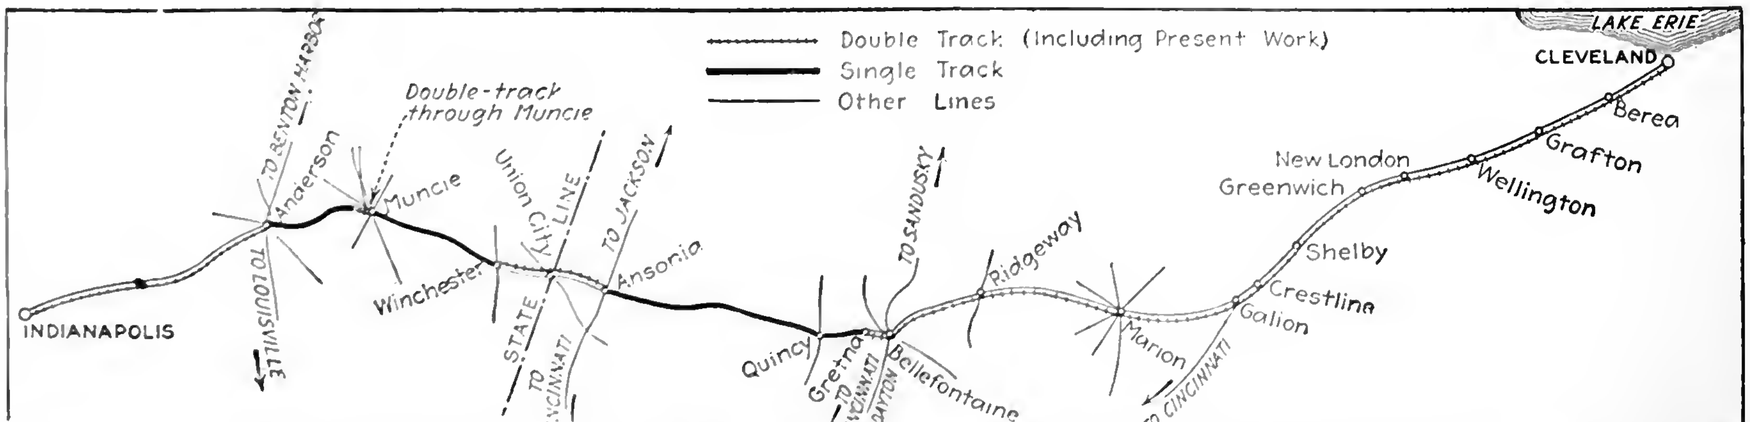
Double-Track Improvement on Big Four Railroad

Study of Operating Conditions for Heavy Traffic Leads to Extending Second Track and Reducing Grades

INCREASE in traffic capacity, more rapid forwarding of freight, and eventually—on some parts of the territory—an increase of train loads from 2200 to 4000 tons, are operating advantages which will be effected by the double-tracking and grade-reduction work and other improvements on the Cleveland and Indianapolis division of the Cleveland, Cincinnati, Chicago & St. Louis Ry. This 283-mile line is the busiest division of the "Big Four" system. It has about six passenger trains and seven scheduled freight trains each way daily, but the traffic density is much greater than would be indicated by the number of scheduled trains. The actual total number of trains during the war period, with the heavy traffic in munitions and supplies, has been as high as 40 to 50 daily.

In this distance there are 150 miles of double track, which the work in progress will increase to 200 miles. This includes the 20-mile stretch between Galion and Marion, Ohio, where the parallel and adjacent single-track lines of the "Big Four" and the Erie railways are operated jointly as a double-track line. Other improvements include an extension of the west-bound yard at Bellefontaine and new engine terminals at Galion and Ansonia, Ohio. At present the maximum grades are 0.8 per cent., in short stretches, but with the completion of the improvements this will be reduced to 0.3 per cent., with some temporary exceptions, as noted below.

The economic and operating phases of the work are



DOUBLE-TRACKING ON 283-MILE HEAVY-TRAFFIC LINE OF CLEVELAND, CHICAGO, CINCINNATI & ST. LOUIS RAILWAY

of primary importance, the construction phase involving no great difficulty. The improvement thus far authorized is not expected to permit of hauling heavier train loads, but it will permit the handling of trains with a great saving in time, due to the elimination of delays from side-track detentions and congested conditions at various points.

Two engine districts compose this division: One is 135 miles, from Indianapolis to Bellefontaine, and the other is 140 miles, from Bellefontaine to Cleveland. Hitherto the maximum train loads permissible over the ruling grades have not been handled through these districts, because of the great distance and the fact that the delays and congestion attending the dense traffic would make it impracticable to handle such trains within the time limits for working hours of train crews, as imposed by law. Changes in the engine districts were considered, but the other methods of meeting the difficulty were considered preferable. In this connection, reference may be made to the rearrangement of a 309-mile division on the Great Northern Ry. into three engine districts instead of two, in order to keep within these time limits, as described in *Engineering News-Record* of Sept. 5, 1918, p. 439. In this case, however, the traffic was very much lighter than that on the Indianapolis and Cleveland line.

Ruling Grades Not All Eliminated

While grade reduction is included in the present improvement, it does not eliminate all the ruling grades in either of the two train districts, but at certain points these ruling grades will still remain on single-track sections outside of the double-track construction now authorized. The new double track, as built for some distance both east and west from Bellefontaine, and, therefore, including both the train districts, is also laid at the old grades, of 0.8 per cent., which are ruling grades, except that east-bound from Bellefontaine the ruling grade is 0.5 per cent. If the two districts were so improved as to reduce the grades at all other points, it would be possible to increase the train loads correspondingly, using pusher engines on the Bellefontaine grades. On the remaining portions of the districts, therefore, the maximum grades on the new double-track work are 0.3 per cent. These portions are being thus treated with a view to their becoming parts of a low-grade line between Indianapolis and Cleveland, such as will be attained eventually either by the reduction of present grades, by the construction of low-grade detours around the heavy-grade sections, or by the application of helper service.

In the case of this division, the need of immediate relief—at least to the extent attainable by double tracking both ways from Bellefontaine and at certain other places, as now in progress—was so pressing as to leave no alternative. Previous experience of this railway as to benefits from double tracking elsewhere under approximately similar conditions left no doubt as to the economy of this particular improvement, which was undertaken, therefore, without making such close study and estimates as would have been necessary to demonstrate the full measure of the benefits which will be derived.

Work now in progress includes the widening of present fills and also the construction of new and higher fills on the present location, in order to substitute long unbroken grade lines for the original irregular profile. It includes three sections, as shown on the accompanying map. From Marion, Ohio, west to Harper, 33 miles, the work is mainly in widening the old fills, and requires relatively light grading. From Ansonia, Ohio, to Union City, eight miles, the subgrade elevation is raised considerably, in order to reduce grades by taking out existing sags. From Union City to Winchester, Ind., 10 miles, there are both widening and raising of fills. The estimated cost is $1,180,000 for the work from Marion to Harper, and $820,000 for that from Ansonia to Winchester. As this line traverses mainly an elevated plateau there are few cuts of importance and few structures other than culverts.

Double Tracking and Passing Tracks

In double tracking, the new second track is in some places on the north and in other places on the south of the old track, which arrangement permits of some improvement in curvature and also permits of taking advantage of the best location for grading and other local conditions. Present passing tracks, which are about six miles apart, are linked into the double track, being ballasted to standard section and relaid with new rails. Passing tracks are required also on the double-track sections, where they are spaced about 10 miles apart, their location being determined more by the occurrence of yards, towns and road crossings than by any specific interval or spacing. These new passing tracks are made long enough to take 100-car trains.

Train movements will be facilitated greatly by the installation of automatic block signals, which it is expected to install later. With this system the block sections will be about one mile in length, as compared with six to seven miles under the present manual-block system, which has towers at the passing track connections.

Rails for the new tracks are of the A. S. C. E. 90-lb. section with four-bolt joints, laid on ties of red oak and similar woods which are creosoted at the railway's plant. Main tracks are spaced 13 ft. on centers and the spacing of main and passing tracks is 16 ft. on centers. Concrete posts of the railway's design and manufacture carry the woven-wire fencing, special braced posts being used at corners and end panels. Mile posts and rests for spare rails are also of concrete.

These improvements are under the direction of C. A. Paquette, chief engineer of the Cleveland, Cincinnati, Chicago & St. Louis Ry. W. C. Kegler is district engineer for all the present work, with F. N. Johnson as resident engineer on the section from Marion to Bellefontaine and T. E. Earle as resident engineer from Ansonia to Winchester.

Railways Should Report Road Crossings

Legislation requiring railways to obtain the approval of the Wisconsin Railway Commission for all new road crossings and abandonment or change of existing crossings is suggested by the commission. Discovery of new crossings established without any report of the fact by the railway to the commission is the reason for this suggestion.

Smooth, Dustless Roads Maintained by Gang System

Bituminous Carpet Placed on Macadam Highways in Michigan Fruit District —Slag Has Proved Satisfactory for the Metal on These Roads

BITUMINOUS carpets maintained by the gang system, as distinguished from the patrol system, are used to cover the slag and stone macadam roads in the Berrien County, Michigan, fruit district. Thus smooth and dustless highways for the hauling of perishable fruit to market are produced. While stone has been used generally for these roads, slag is coming into favor and is said to be giving excellent results. Reports indicate that stone is preferred when bituminous treatment is not contemplated, while many favor slag when such treatment is to be applied.

BITUMINOUS CARPET PROTECTS EIGHTEEN-YEAR-OLD MACADAM ROAD IN BERRIEN COUNTY, MICHIGAN

As stated above, an important factor in deciding road questions in this county is the fruit industry. Peaches, grapes and berries in large motor-truck loads will not reach the shipping point in good condition if bumped over rough roads and covered with dust. Therefore, farmers in this district insist on having the roads maintained in first-class shape. Furthermore, the elimination of dust is of great value to fruit growers whose farms border the highways. One of the accompanying views shows the West Michigan Pike—an 18-year-old water-bound macadam which has received a bituminous treatment.

While slag has been used extensively in Michigan for several years as the base course for stone and gravel surfaces, only in recent years has it been employed for the top course. It is a little more troublesome to compact slag than stone in thin courses, and, according to Frank F. Rogers, state highway commissioner, stone is preferable for the wearing course in water-bound macadam, as the lower cementing property of slag causes it to ravel more quickly under automobile traffic. Where a bituminous carpet is to be applied, however, slag is said to make a very satisfactory surface on which to place the coating. In fact, it is said to be superior to gravel and stone, since it not only is sharp and irregular, but has minute cells which receive the bituminous material, thus causing the carpet to adhere.

Slag has proved satisfactory for two miles of macadam in Berrien County, it is stated, and is now being used quite extensively. An example of this is found in Benton Township, which is now building 22 miles of slag-macadam road under a bond issue of $100,000. As this sum was not sufficient to construct the roads under conditions of increased material and labor cost, the township board adopted a policy of building the slag base on all the roads and utilizing it for traffic until funds for surfacing are available. One of the views shows the township unloading and distributing plant at Benton Harbor, which, with a force of only three men, keeps 16 teams and two motor trucks busy.

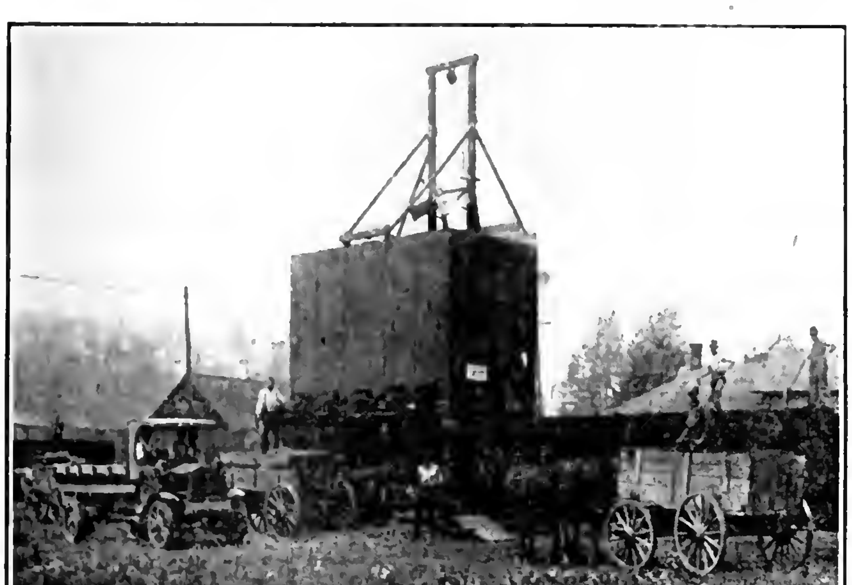
Macadam county roads for which state aid is desired must be built in conformity with the specifications of the state highway department, under whose instructions and specifications the county engineer works. Township roads are also built according to the state specifications under the supervision of a highway commissioner, the county engineer being generally employed to make road surveys, check the grade and do some inspection work. The state specifications, with few exceptions, follow those used elsewhere for macadam roads. The stone, whether limestone or slag is used, must be well graded and of sizes from 1½ to 3½ in. This grading is the same for both the top and bottom courses. Screenings are described as that portion of the crushed material passing a ¾-in. screen, including the chips, but with all but 25% of the dust removed. Dust is described as that portion passing a No. 8 sieve. The engi-

neer for the company supplying the slag maintains that this dust should be left in the screenings for the top course, as it would give better cementing properties.

Side boards, supported by iron pins driven into the subgrade, are used as forms and to insure proper thickness of material. These forms are used for both the top and bottom courses. To obtain adequate rolling, the county specifications require that, before starting to lay stone, the contractor shall have one roller on the work for each 100 cu. yd. of material which he expects to deliver per 10-hour day; also the necessary pumps and sprinkling outfits. Rollers shall weigh from 10 to 15 tons. The compacted thickness of the bottom course is required to be 4 in., while that of the top course is such as will give a final thickness of not less than 7 in. at the edges and 8 in. at the center, for 9 to 16 ft. paved width.

As a rule, the bituminous carpet cannot be applied immediately after the completion of the top course, as the road is then covered with more or less loose screenings, which prevent proper adherence. In general, it is thought best to permit the use of the top course by traffic until it has become thoroughly compacted and bound by the cementing action of the material. Experience in some cases indicates that water-bound slag macadam can carry traffic for a longer period than stone before the carpet is applied.

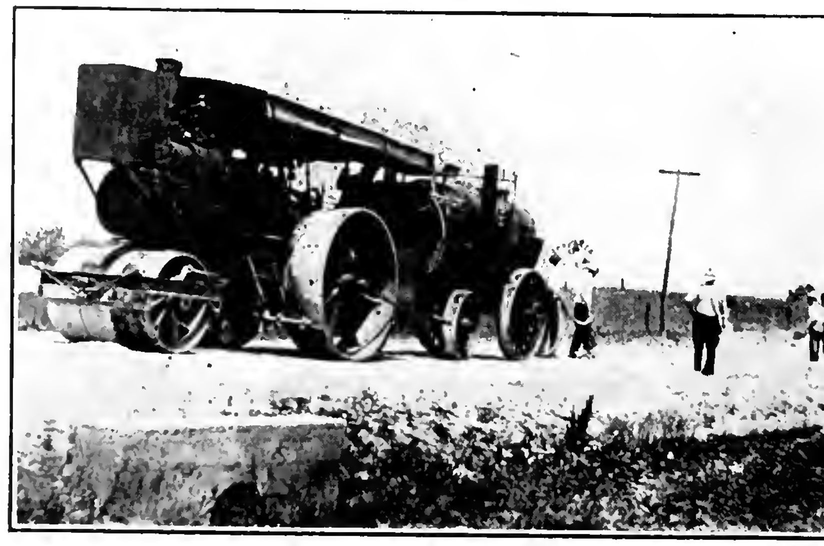
For the bituminous carpet the county uses asphalt with both stone and slag screenings from ¼ to ½ in. in



THIS UNLOADING PLANT KEEPS SIXTEEN TEAMS AND TWO MOTOR TRUCKS BUSY

size. After the surface has been swept thoroughly, the asphalt is applied at the rate of ¼ to ½ gal. per square yard, by means of a 700-gal. tank wagon having a heater to keep the contents at about 320° F., and an air pump to maintain a pressure of from 30 to 60 lb. per square inch. An illustration shows one of these outfits at work. The asphalt is usually applied with a hose fitted with a ⅝-in. nozzle, which sprays the material downward, in conical form. This enables the man in charge to vary the quantity according to the condition of the road. Screenings averaging from 18 to 25 lb. per square yard are then spread and rolled, and the road is immediately opened to traffic. The carpet is said to stand up well under heavy motor-truck traffic; what wear occurs is usually in the form of holes of varying size, rather than in long ruts.

The width of roadway is 24 ft. between ditches, and the paved width is from 9 to 18 ft., according to the importance of the road. Shoulders are built before the stone or slag is deposited, the earth being filled against the side forms. In the final rolling, after the side forms have been removed and the space has been filled, the shoulders as well as the macadam are rolled. Main county roads passing through villages are paved for the full width of the street, the village paying for the extra width over the standard 16 ft. This system has greatly



ROLLER HAULS HOT ASPHALT SPRAYING OUTFIT WHILE LAYING BITUMINOUS CARPET

facilitated the construction of through routes. In such cases the village can specify the kind of paving to be used within its limits.

Drainage of the subgrade in the country sections is provided by lateral drains of coarse stone or slag laid through the earth shoulders to the ditches. These are about 100 ft. apart on both sides of the road, and are staggered so as to give one drain for every 50 ft., with one on each side at all low points. Storm-water drainage on grades is provided for by wide concrete gutters ending in an apron or spillway at the foot of the grade, which discharges the water clear of the roadway. On high fills a similar gutter is used, with a concrete spillway down the slope to prevent washing. Under the cross roads, which are paved similarly to the main roads for a distance of 33 ft., side ditches are carried by 10- or 12-in. sewer pipe cased in 3 in. of concrete where the covering is shallow. Bridges have their decks placed 6 in. below grade to allow for the carrying of the macadam surfacing over them.

There are about 150 miles of road in Berrien County, of which 135 miles are of macadam with bituminous carpet. These are generally built by contract and are maintained by the county with state aid. The work is supervised by three county road commissioners appointed for six-year terms by the board of supervisors, and they appoint an engineer. Recently the state has created the position of county superintendent of maintenance, the incumbent, to be appointed by the road commissioners, to be, preferably, an engineer skilled in road work. In addition to the above there is a total of about 50 miles of township road, 40 miles of which are stone macadam. Some of the townships have their own rollers and other complete equipment, and take care of both the construction and maintenance, and, as mentioned above for Benton Township, the roads are frequently used for two years before receiving the bituminous-carpet treatment.

Road maintenance on the intensive or continuous plan, as practiced in Berrien County, is done by traveling gangs, as distinguished from the patrol system. From early spring to late fall the county operates three gangs, one under each of the three commissioners. They travel over routes laid out according to the traffic density and the condition of the roads, looking for and repairing incipient holes, ruts and general wear, and cleaning ditches and drainage structures. In this way heavy, periodical repair work is avoided, and the roads are maintained in good condition. The engineer states that the average cost is $250 per mile per year.

Each gang consists of a foreman and three or four helpers. The plant consists of a motor truck, a 110-gal. heating kettle and the necessary shovels and other tools. The daily pay averages $3.50 for the foreman and $3 for the laborers. The foreman receives daily instructions from the commissioner, and the distances are such that with a 10-hour working day the men can go home at night, riding to and fro on the truck.

How the Repair Work Is Done

When work is begun in the spring, the first thing is to clean out the ditches and culverts and trim the shoulders. Patching of holes and worn spots in the macadam begins with warm weather. Road asphalt, heated to about 300° F., is used for this work. Where the holes appear the surface is loosened with picks, and the dirt and loose material are swept from the road; stone screenings or slag chips are then filled in, hot asphalt or tar is poured over them, and, after a top dressing of screenings has been applied, the patch is tamped to a smooth surface. Unless the patches are large, no attempt is made to keep off the traffic. One gang will patch from one-half mile to two miles of road per day, depending on its condition.

Weekly reports are sent by the foreman to the superintendent of maintenance, who is one of the commissioners. The roads are named and numbered, while each road is divided into lettered sections. The foremen keep account of the labor and material used on each section and enter the figures on their reports; thus the bookkeeper for the commissioners can keep an accurate account for each section.

Maintenance funds for county road work are derived from road rewards and repair rewards paid by the state, supplemented by one-half the automobile license tax of the county. There is also an annual property tax of two mils for road construction and maintenance.

The county road engineer for Berrien County is James Hampton, of St. Joseph. L. Snyder, one of the commissioners, is superintendent of maintenance. The engineer is appointed by the commissioners for a two-year term, and has one office assistant and one field engineer. His main duties are to make surveys, plans and profiles for new roads, and supervise the construction. During the working season he spends about two-thirds of his time supervising the work being done on the roads.

Chicago Union Station to Spend $5,300,000 in 1919

Work Includes Deep Foundations for Head-House, Street-Approach Viaducts and Partial Rearrangement of Tracks

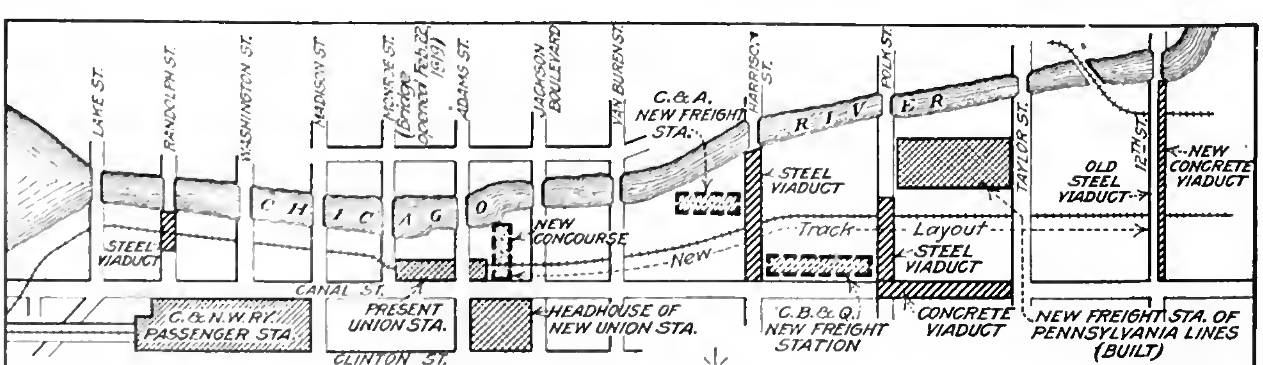
VIADUCTS of steel and reinforced concrete, foundations for head-house and concourse, and construction of a part of the permanent track layout, constitute the principal work to be done this year on the new union station, Chicago. This is estimated to cost $5,300,000 out of the total cost of nearly $60,000,000, which included $30,000,000 for land. The location of this work is shown on the accompanying plan.

Canal St., running parallel with the tracks and along the boundary of the railway property, will be elevated about 10 ft. and from Harrison St. to Taylor St. it will be carried on a viaduct, the space beneath this structure being utilized for tracks. This viaduct will be of reinforced concrete. Its construction this year will be confined to the one block between Taylor and Polk Streets.

Transverse viaducts will extend from Canal St. across the railway property to connect with the river bridges. The 12th St. viaduct will be of reinforced concrete and its south half is to be built this year. Steel will be used for the viaducts at Taylor, Polk, Harrison and Randolph Streets.

At the passenger station, old freight houses between the present station and the river will be torn down, and some of the permanent tracks will be laid in this space, thus increasing the facilities and reducing the present congestion, which results from the limited number of station tracks. Foundations of part of the concourse will be put in at the same time. This concourse will extend between the ends of two groups of stub tracks, which in the new station will take the place of the present through tracks. In other words, the station will be converted from one of the through type to one of a double-end stub type. At the same time it is expected to build four tracks of the permanent six-track approach on the south, extending from the station as far as 12th Street.

Foundations for the head-house can be put in without interfering with existing facilities, as the site is entirely outside of the present station property, and occupies an entire city block. Concrete piers built in wells or open caissons, sunk about 70 ft. to hardpan, will support the steel-frame superstructure. The site was cleared some time ago, and is now being excavated to the basement level, preparatory to sinking the wells.

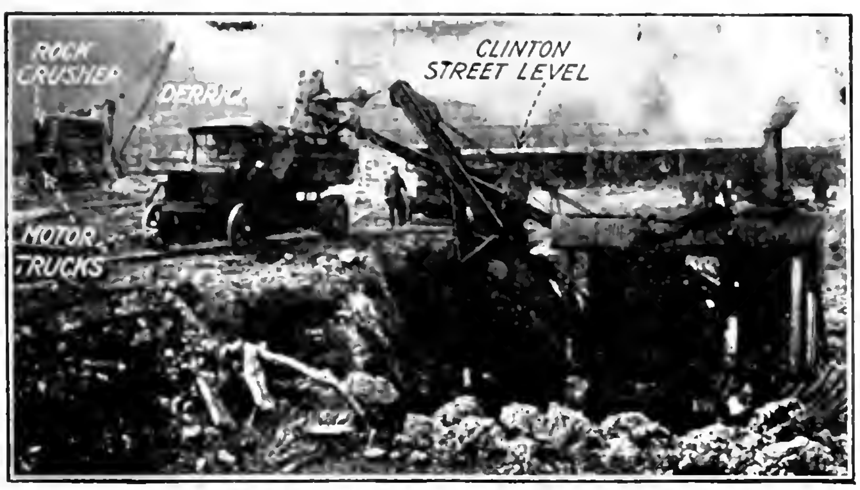


PLAN SHOWS 1919 WORK FOR CHICAGO UNION STATION

Steam shovels are used on this work, useless material being removed in motor trucks, while stone from old footings is crushed and screened on the ground and stored for use in the concrete.

In the steel viaduct construction the steel framing will be covered with concrete or gunite applied by the cement gun over wire mesh wrapping and having a minimum thickness of 1½ in. In general, the design consists of three-post bents carrying cross-girders for a 38-ft. roadway, while cantilever brackets carry 14-ft. sidewalks. Ten lines of plate-girder stringers are framed between the cross-girders, four of the stringers being directly under the rails of the street-car tracks. The roadway deck is a reinforced-concrete slab resting on the steel frame, with wood-block paving laid directly upon this. The 6-in. sidewalk slabs are carried above the girders, being supported by concrete beams at each end.

The bents are spaced longitudinally at varying distances to suit the track layout, and will be embedded



CLEARING SITE FOR HEADHOUSE

in concrete curtains or piers to form a protection against derailed trains. The columns are of H-section, built up of two channels, a web plate and four angles, with batten plates over the flanges of the channels. All viaducts are figured for a live load of two lines of 50-ton street cars on tracks spaced 10 ft. on centers in the middle of the roadway, with 100 lb. per square foot on the unoccupied parts of the roadway and on the sidewalks.

Two-post bents are required at certain points on account of track clearances. In such cases the posts are spaced about 54½ ft. on centers, coming under the sidewalks and carrying heavy cross-girders whose ends have a cantilever projection of 5 ft. 3 in. Where the viaduct is adjacent to the buildings and driveways of the new freight stations, longitudinal expansion joints are provided along the edge of the sidewalk. These are made with deep 1½-in. copper troughs or flashing, filled with asphalt mastic.

All work for the Chicago Union Station Co. is under the direction of Thomas Rodd, chief engineer; J. D'Esposito, assistant chief engineer, and A. J. Hammond, principal assistant engineer. Viaduct designs must be approved by the city authorities. All track work is done by railway forces. Contracts for the 1919 work already let are as follows: Head-house foundations, John Griffith & Sons; steel superstructures for the Polk St. and Taylor St. viaducts, American Bridge Co.; substructure for the Harrison St. viaduct, the W. J. Newman Company.

Other work which is independent of the union station, but is necessitated by the rearrangement of the terminal, includes two large freight stations for the Chicago, Burlington & Quincy R.R. and the Chicago & Alton R.R.

The former station has the foundations partly built, and it is expected that about $3,000,000 will be spent this year on foundation work and superstructure. It is expected also that work will be commenced on the latter station, which is to cost nearly $2,000,000.

Residual Strains in Cast-Iron Car Wheels

During the investigation of a railway accident caused by the breakage of a freight-car wheel, the Interstate Commerce Commission recently made measurements of the residual strains in the metal of chilled cast-iron wheels. Relatively high strains were found, of such a nature as to be readily explained by the contraction during cooling in manufacture. In spite of these high strains, the investigation showed that the wheel did not break from internal causes, but was undoubtedly damaged through external violence, probably the impact of a fallen part of the brake rigging, which cracked off part of the wheel flange, this in turn causing the wheel to break apart by its pounding on the rail. Because it represents a further application of the method of studying internal strains which J. E. Howard of the commission's Bureau of Safety has used in rail studies for some years, the investigation is of general value.

Through the cutting rings from a car wheel at six different radial distances from the center, and measuring the shortening of gage-lines on these successive rings, it was found that compressive stresses existed in the rim and the hub of the wheel, and tensile stresses in the web or plate. The hub stresses were high, ranging to more than 25,000 lb. per square inch compression; the rim stresses did not materially exceed 2500 lb. compression. In the plate there were tensile stresses in the neighborhood of 2000 lb. per square inch. These stresses were computed from the measured shortenings and extensions by multiplying by 17,000,000 lb. per square inch, the modulus of elasticity.

While these stresses are of some importance, they are not large enough to suggest danger. In the wheel which broke under the train, moreover, the investigators found clear evidence of the fracture having started at the rim and grown toward the center. There were no defects in the fracture, and the rim of the wheel showed no burned or otherwise damaged spots. The wheel had been in service only two months, having been placed on the axle in December, 1916. It broke while running in a New York Central freight train near Waterloo, Ind., on March 25, 1917. It was evident that the fracturing process had proceeded rather slowly after the piece of flange was broken off; the train ran nearly 1000 ft. before the last fragment of the wheel left the axle. While no direct proof was obtainable that a piece of the brake rigging started the breakage, the commission's report, published in a bulletin just issued, states that no other explanation of the facts of the accident was found to be tenable.

Move Bridge Spans 136 Feet Endwise on Car Trucks

Two Lines of Steel Trucks on Falsework Carry Hydraulic Jacks Which Raise Three Spans Together and Support Them While Hauled by Cables

RECONSTRUCTION of the combined railway and highway bridge of the Union Pacific Ry. across the Missouri River at St. Joseph, Mo., in 1917-18, included as its principal features the building of new piers, the shifting of three 300-ft. truss spans longitudinally into new position, and the building of a new drawspan. The bridge had to be kept in service during the work, except for the short time required to shift the spans. Traffic averaged about 75 trains and 400 teams and automobiles daily. River traffic also had to be provided for until the close of the navigation season. Indications of weakness in the old piers having made a new substructure necessary, it was proposed to build new piers on the downstream side and move the bridge laterally into its new position. The War Department, however, required that in connection with the alterations a longer drawspan should be provided. This new condition led to the plan of locating the new piers between the old ones and moving the spans longitudinally into position. The superstructure work included the following, in the order given; Rolling three spans lengthwise; building a new 465-ft. swing span; rolling an 80-ft. girder span lengthwise 28 ft. and building a new 60-ft. girder approach span; removing the old 358-ft. swing span. The alignment is straight and unchanged, but the new rail level is 18 in. higher than the original. Construction of the new piers was described in *Engineering News-Record* of Oct. 25, 1917, p. 781, while the moving of the fixed spans was noted in the issue of Nov. 22, 1917, p. 989.

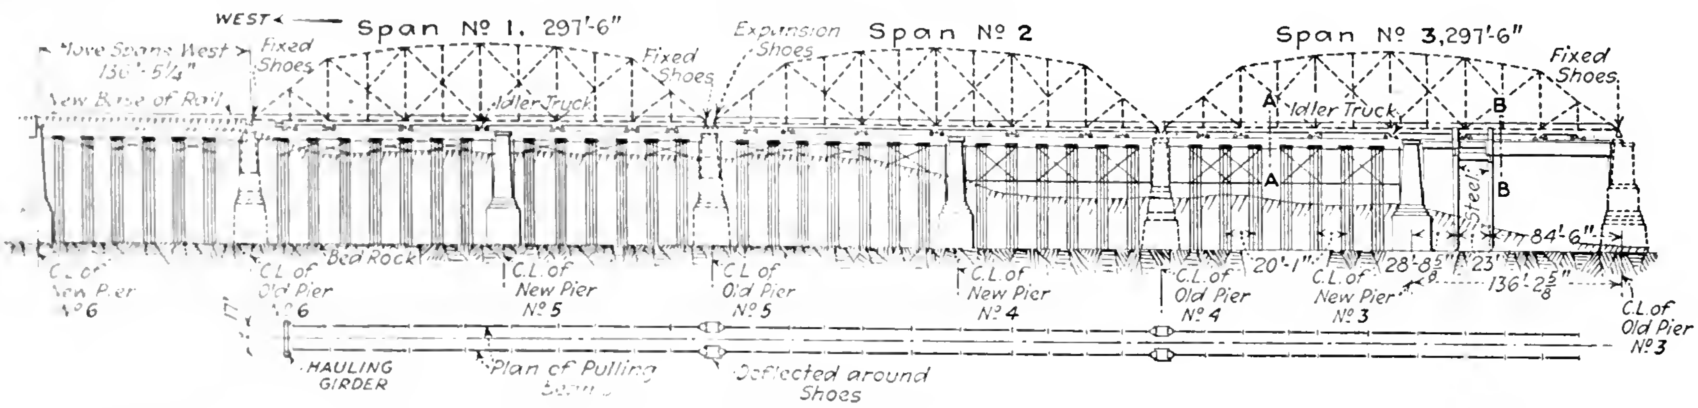
After the new piers had been built, the first stage of work on the superstructure was the shifting of the three through spans of 300 ft. each. This consisted in moving them 136 ft., to land them on the new piers. They have trusses of the Pettit type, 50 ft. high and spaced 17 ft. on centers, with a single track between them. Floorbeam brackets 48 ft. long carry 15-ft. roadways outside of the trusses.

BRIDGE SPANS ARE HAULED BY CABLES

Car trucks traveling on falsework and carrying hydraulic jacks were used for moving the 300-ft. spans. They were mounted on two tracks directly under the trusses, with the jacks at the panel points. There were 14 trucks to each span, but the two under the middle panel points carried only blocking, which was built up close to but not in contact with the trusses. This arrangement provided a rigid support in case failure of any one jack should throw excessive load on the other jacks. Semicircular shims were built up around the plunger of each jack and kept within a short distance of the plunger head, so that in case of loss of pressure or the failure of a jack while the bridge was being moved the span would come to a solid bearing with very slight settlement. No such failure occurred, however. For operation the jacks were arranged in two groups, each with its own steam pump, this arrangement being necessitated by the difference in the diameters of the jack plungers. For the west span there was a group of 12 jacks of 500-ton capacity with 12½-in. plungers. The other two spans had a group of 24 jacks of 300-ton capacity with 10-in. plungers. All jacks had strokes of 9 in. The heavier jacks were used because they were on hand. The average load on the jacks being only about 70 tons, the pressure on the jacks, piping and pumps was only 2500 lb., while the capacity pressure was 10,000 pounds.

To equalize the load on the jacks, every jack in each group was connected by ¼-in. flexible copper tubing to a pressure line of ¾-in. extra-strong steel pipe with forged fittings. The steel pipes were laid on the floor beams, outside of the track ties. A shut-off valve and bleeder valve were placed at each connection to these pipes, for convenience in changing the packing if leaks should develop, but this precaution was not required.

A denatured alcohol mixture was used in the jacks on account of the cold weather, about 400 gal. being sufficient for the raising of the spans 30 in. by the 36 jacks,



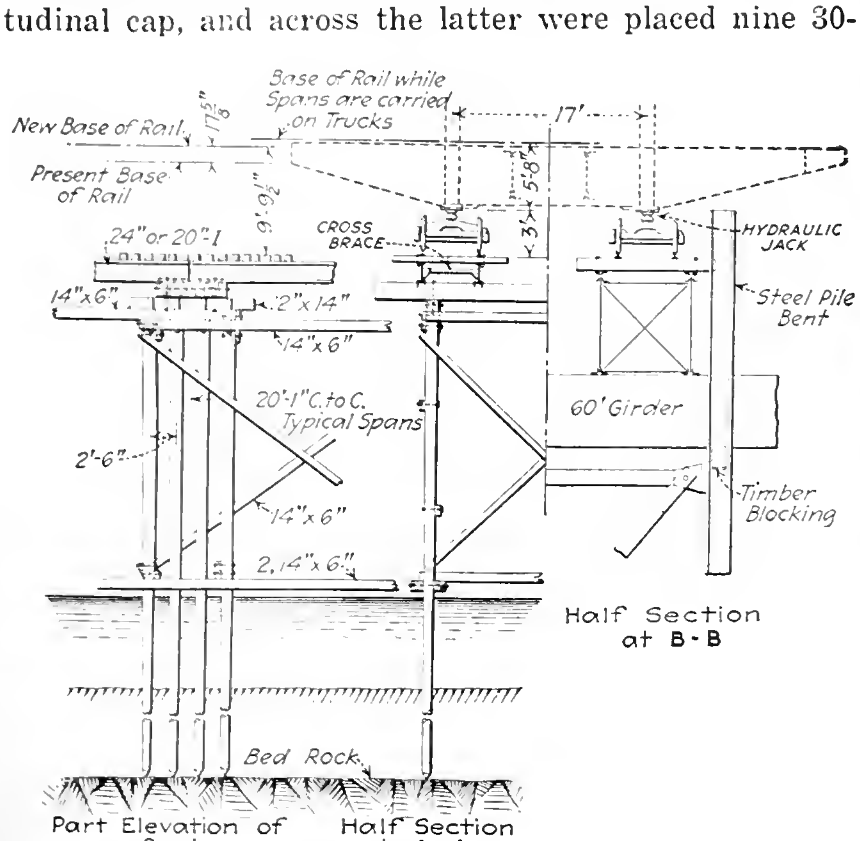
THREE 300-FOOT BRIDGE SPANS ARE MOUNTED ON TRUCKS AND SHIFTED 136 FEET TO NEW PIERS

and then for supplying them during the moving of the spans. Readings were taken at regular intervals. Static loads registered 1700 and 2200 lb. per square inch for the 500-ton and 300-ton jacks respectively, these readings being taken after the pumps were shut down. Surge loads, with the pumps in action, registered from 2300 to 2500 lb. per square inch for the heavier and 2700 to 2800 lb. for the lighter jacks.

Maximum working load for the 300-ton jacks was calculated at 2450 lb. per square inch, which was taken as the static load after the bridge was raised and the pumps were stopped. Raising the bridge 18 in. to its new grade was done with eight jacks per span. These were placed on the piers and operated gradually between trains, so as to maintain the proper run-off or incline in track on the fixed spans and the swing span. This jacking extended over a period of several days.

The falsework for the rolling track consisted of piles supporting 24-in. I-beam stringers, except that an 80-ft. girder span was used at the east end, where the water was deep and swift. Framed bents were seated on the footings of the old and the new piers, being secured by cables and fox bolts. Piles were arranged in two rows, one outside each line of trusses. They were in groups of four, those of each group spaced 30 in. on centers while the groups were 20 ft. on centers, connected by horizontal and diagonal bracing in two directions.

At each group, four cross caps carried a 12-ft. longitudinal cap, and across the latter were placed nine 30-ft. timbers 8 x 17 in. These were laid solid to form a bearing for the I-beam stringers, which were in pairs, with riveted connections between the webs. Across them were the 8 x 8-in. ties, 4 in. apart, to which were spiked the 75-lb. track rails.

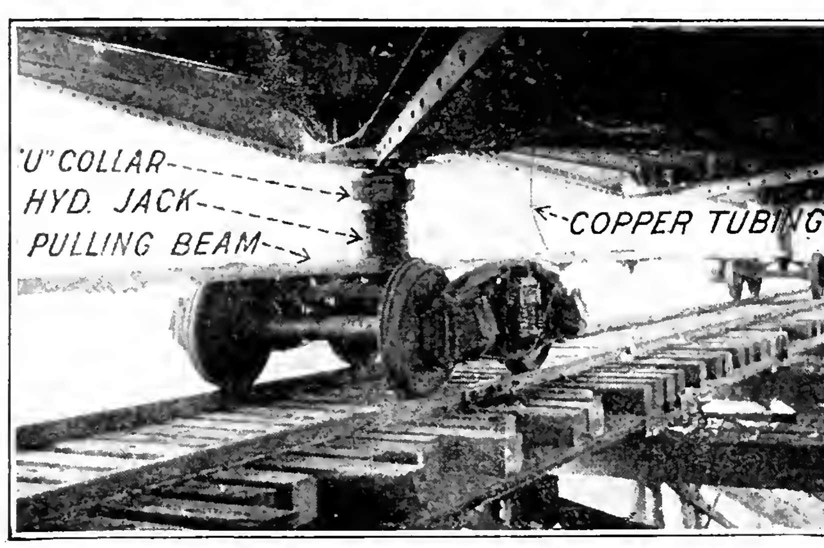


FALSEWORK CARRIES TWO LINES OF TRACKS WITH HYDRAULIC JACKS UNDER THE BRIDGE CHORDS

Piles were of longleaf yellow pine, 40 to 70 ft. long, driven to rock or to absolute refusal, and having an average penetration of 25 to 30 ft. They were driven by a steam pile-hammer in swinging leads which were suspended either from the boom of a locomotive crane or from the projecting ends of a heavy timber laid across the top chords of the trusses.

Steel trucks used for rolling the spans were of the standard type for 50-ton freight cars. They had cast-steel frames and bolsters and were rated at 160-ton capacity. The jack on each truck was seated over the king-pin and anchored rigidly by bolts passing through the flanges of its base and through timber blocks inserted in openings in the bolster. To provide against failure of some detail part every truck was tested to 100-ton load at the site, a special testing frame equipped with hydraulic jacks being constructed for this purpose.

A rigid pulling beam connected the 21 trucks on each side, this beam being composed of a pair of angles bolted to plates which fitted over the heads of the king-pins of the trucks. The upstanding legs of the angles were cut away to admit of seating the base of the jack on the truck bolster.



CAR TRUCKS WITH HYDRAULIC JACKS MOVE SPANS

Across the forward end of the two front trucks was a girder composed of a pair of heavy I-beams laid flat and connected to the two pulling beams. To this girder were attached the blocks of the hauling tackles. To transmit the pull from the girder directly to the spans as well as to the trucks, steel cables were run from the girder to one of the floor-beams of the first span, these lines being drawn tight by steamboat ratchets.

Hook bolts held the end shoes to the trusses when the spans were raised.

The hauling was done by four sets of 4-sheave blocks, each rove up with a nine-part tackle of 1½-in. manila rope. Two of these sets were handled by an 85-hp. steam hoist and the other by a 200-hp. electric hoist, these hoists being placed just back of the new west abutment. The load pulled was about 2760 tons, including the three spans, 42 trucks, 36 jacks and the pulling attachments. Of this total, the three spans represented 2520 tons.

Preparations for moving the spans were begun in August. Traffic was not interrupted until the day of the moving, Nov. 14, when the railway and the highway were closed from 8 a.m. to 5:40 p.m. The rolling of the spans a distance of 136 ft. consumed only 13 min., the remainder of the time being occupied in getting ready and in closing the 136-ft. gap left at the east end. For this latter purpose pony bents were set on blocking on the falsework used for the rolling tracks. These carried timber stringers for the track and roadway decks. Construction of the new drawspan, which was done while keeping the bridge open for traffic, will be the subject of a separate article.

The above work was done for the St. Joseph & Grand Island Railway Co., under the direction of R. L. Huntley, chief engineer of the Union Pacific System, with H. M. Stone as resident engineer, the entire project being under the general supervision of E. E. Adams, consulting engineer of the Union Pacific System. The American Bridge Co. was the contractor, and the work was carried on under the personal supervision of K. L. Strickland, division erecting manager, T. S. Melton, foreman, and A. F. McLane, resident engineer.

Transverse Fissures in Rails and Phosphorus Segregation

Longitudinal Streaks Attributed to Phosphorus Are Found at Nucleus of Rail Fracture by Copper-Chloride Etching

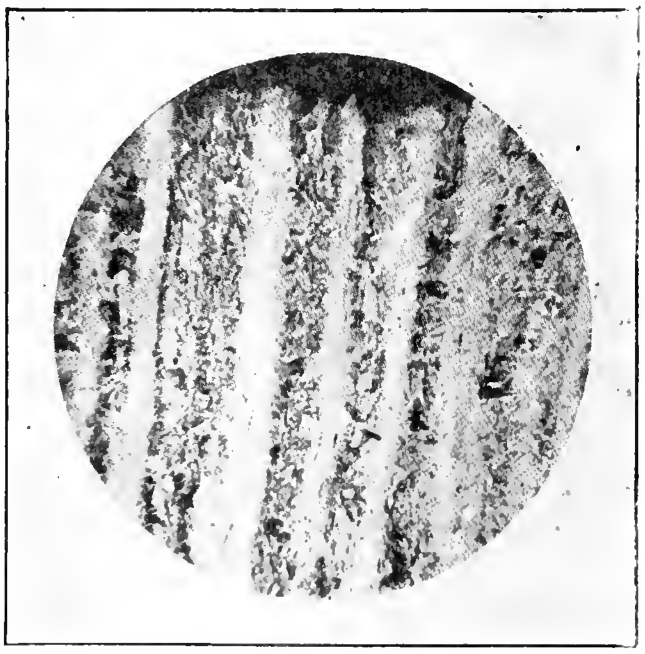
NEW micrographic studies of broken rails have recently led G. F. Comstock, metallographist of the Titanium Alloy Manufacturing Co., Niagara Falls, N. Y., to suggest an explanation of transverse fissures that in a measure bridges the gap between the opposing views current for some years past. According to his findings, brittle streaks of high-phosphorus steel in the rail head constitute the initial weakness from which a transverse fissure starts.

J. E. Howard, of the Interstate Commerce Commission's Bureau of Safety, has maintained that excessive stress in service in the track is responsible for transverse fissures, and that the only cure is the adoption of a heavier rail section. His experimental proof of high residual stresses in the center of the rail head, and his discovery of large compressive stress along the running surface from the rolling action of the wheels, which shifts the zone of maximum tension to the interior of the head and adds the effects of service stress and residual stress, supported the overstress theory. Transverse fissures are generally conceded to be detail or "fatigue" fractures, but in most cases it has been impossible to discover chemical or structural defects in the steel at the center or nucleus of these fractures, so that it seemed necessary to conclude that overstress initiated the fracture.

Railway men, on the other hand, adhered to the belief that defective quality of rail steel is at the root of the fissure trouble. Mr. Comstock presents evidence of a minute defect at the nucleus of transverse fissures, namely, streaks of steel abnormally high in phosphorus content. He has concluded that the initial crack or check in the rail head occurs in such a brittle streak and that progressive detail fracture follows. Further, he found from the records of 36 rails that long soaking of the steel in the furnace before rolling prevents fissuring, presumably by allowing the phosphorus to diffuse through the mass, and thus preventing the formation of the brittle streaks. This fact, if confirmed, provides a method of combating the fissure trouble in rails.

In these investigations, failed rails were sawed apart longitudinally at the fracture, and the surfaces so prepared were polished and then were etched with copper chloride. This reagent deposits a film of copper on normal steel, while certain special constituents, among them steel of high phosphorus content, remains bright. The inverse effect could be obtained by picric-acid etching, which darkens high-phosphorus areas.

A typical microphotograph of such an etched section is reproduced herewith, from an illustration in a paper read by Mr. Comstock before the American Institute of



HIGH-PHOSPHORUS STREAKS IN LONGITUDINAL SECTION OF RAIL AT TRANSVERSE FISSURE, ETCHED WITH COPPER CHLORIDE (× 16)

Mining Engineers at its annual meeting, Feb. 19, 1919, under the title "Metallographic Investigation of Transverse-Fissure Rails with Special Reference to High-Phosphorus Streaks." The broken line near the top of the picture is the face of a transverse fissure. The light bands extending vertically are believed to be high-phosphorus streaks. A prominent streak extends directly to the point where the nucleus of the transverse fissure was located. Closely similar conditions were found in many other rails that had failed by fissure.

Studying all the available rail material—namely, 24 transverse-fissure rails and 12 good rails—all were graded for various different defects in steel quality, including segregation (as shown by sulphur print), presence of slag and similar impurities, segregation of

sulphides, amount of free ferrite, amount of cementite, and finally phosphorus streaking. It appeared that no distinct differences of grading between the failed rails and good rails appeared under any head except that of phosphorus streaks, and under this latter head the majority of the transverse fissure rails were unsatisfactory, while the majority of the good rails were slightly above average quality.

Taking this as indicating the causal relation between the high-phosphorus streaks and fissuring, Mr. Comstock studied the same rails as to origin. So far as data could be obtained, it was found that all the failed rails had been rolled direct from the ingot, while all but two of the good rails had been rolled from reheated blooms. Since the length of time the ingot is hot suffices for carbon diffusion but probably not for phosphorus diffusion, this result appears to confirm the conclusion reached.

Concrete Is Handled in Several Ways on Bridge Abutment Job

HOPPER cars, derrick skips, elevator buckets and inclined chutes were combined in placing 3360 cu.yd. of concrete in abutments and approach retaining walls for a steel highway bridge across the Chicago & Northwestern Ry. at Wheaton, Ill. To give increased headway the bridge is at a higher elevation than the old span parallel to it, so that long inclined approaches were required, practically at right angles to the bridge, as shown by the accompanying plan. Each approach has a retaining wall on one side, and the wall on the south side of the railway is 600 ft. long.

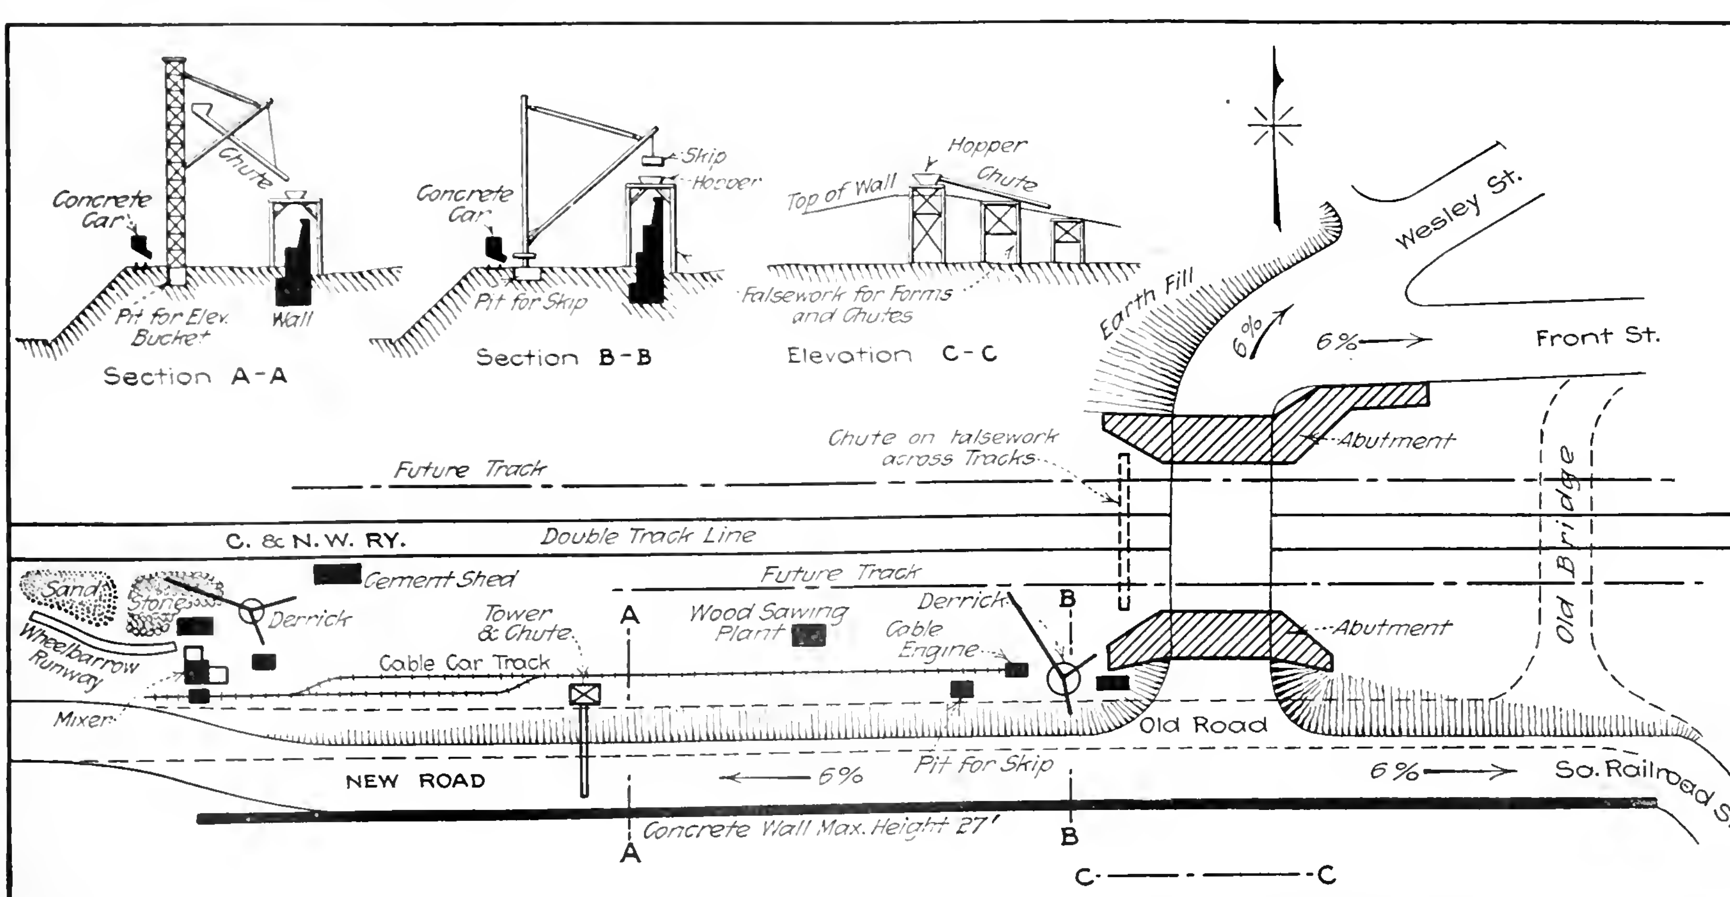
A concrete-mixing plant was located beyond the end of the cut. Sand and gravel were unloaded from cars into stock piles on the side of the adjacent fill, and the stone was loaded into an elevated bin by a derrick with a grab-bucket. The sand was wheeled to the loading chute. The mixer discharged the concrete into a side-gate hopper car.

Between this plant and the bridge site an elevator tower with a chute was erected, while beyond this and close to the abutment was a guyed derrick, both tower and derrick being on the narrow strip between the old road and the top of the cut. A narrow-gage track with one automatic siding extended from the mixer plant to the tower and derrick. This was operated by an endless cable with a hoisting engine placed near the derrick, and on it the concrete was handled in the hopper cars mentioned above.

At first the concrete was delivered to the elevator bucket and spouted to the forms. The tower chute or spout extended across the road and delivered the concrete into lateral chutes supported directly above the forms by falsework. This sufficed for about half the length of the wall.

For the remainder of the work the cars ran up to the derrick and discharged the concrete into a home-made wooden skip which was placed in a pit at the side of the cable track and was handled by the derrick. A movable gate was fitted to one end of the skip, with inclined boards on the inside to guide the concrete to the opening and prevent it from being pocketed in the corners. The skip was dumped into a feed hopper at the summit of inclined chutes carried along and above the forms for falsework.

Concrete for the abutment on this side of the railway was placed directly by the derrick and skip. For the abutment and short wall on the opposite side an inclined chute was extended across the tracks, having a feed hopper at its upper end within reach of the derrick. At its lower end was a vertical drop pipe leading to the head of the chutes over the abutment form, these being



LAYOUT OF CONCRETING PLANT FOR BRIDGE ABUTMENTS AND RETAINING WALL

shifted to deliver the concrete in the desired portions of the form.

Baffles were used at the discharge ends of the long chutes to prevent segregation of the concrete as it was deposited in place. In some cases these were short troughs secured to the trench bracing or form struts, being placed opposite the end of the chute and sloping in the opposite direction, so that the direction of the concrete was reversed just before its final discharge.

This work was done by the Widell Co., Mankato, Minn., under the general direction of O. F. Dalstrom, engineer of bridges, Chicago & Northwestern Railway.

Approximate Formulas Useful in Structural Design

A Few Serve Well When Handbooks Are Not Available—Limits of Reliability, However, Should Be Well Understood

By R. Fleming

American Bridge Co., New York City

FREQUENTLY the designer of steel structures is called upon for information when handbooks and textbooks are not at hand. It is surprising how much may be furnished at such times with a few well chosen approximate formulas. Some approximations are suggested. It is essential, however, that before they are used they be tried out and their degree of approximation well understood.

Radii of Gyration—If d = depth and b = breadth of section, for standard I-beams the radius of gyration, r, = $0.375d$ and $0.20b$. For Bethlehem girder beams $r = 0.42d$ and $0.23b$. In standard I-beams the breadth varies from 55% of the depth for a 6-in. I 12.25 lb. to 29% for a 24-in. I 80 lb. In Bethlehem girder beams the breadth varies from 100% of the depth for an 8-in. I 32.5 lb. to 50% for a 30-in. I 200 lb.

For equal-leg angles $r = 0.3$ of the width of leg when the neutral axis is parallel to either leg. For unequal leg angles $r = 0.3$ of the width of the leg to which the neutral axis is at right angles.

For well-designed columns, if of four angles latticed, $r = 0.4d$ and $0.2b$. If of one plate and four angles, $r = 0.375d$ and $0.2b$. If of one plate, four angles and two cover plates, $r = 0.4d$ and $0.25b$. If of 2 channels latticed, $r = 0.35d$ and 0.6 of the distance back to back of channels when this distance is not less than 0.6 the depth of channels used. If of 2 channels and 2 cover plates $r = 0.4d$ and $0.3b$. (In this connection see an article, "Approximate Radii of Gyration," by O. von Voigtlander, in *Engineering News* of May 23, 1912, p. 991.)

Section Moduli—If W = weight of beam per linear foot, and d = depth; for standard beams 10 in. or less in depth the section modulus, S, $= Wd/10$; for standard beams deeper than 10 in., $S = Wd/11$; for Bethlehem girder beams, $S = Wd/10$.

Safe Load in thousands of pounds for standard beams equals weight of beam per linear foot multiplied by depth in inches and divided by span in feet. (See an article, "Approximate Design in Structural Steel," by George A. Merrill, in *Engineering News* of Mar. 21, 1912, p. 540.) It may be noted that for a uniform load, $M = WL/8$; for a concentrated load $\frac{1}{2}W$ at center of span, $M = WL/8$; for two concentrated loads of $\frac{1}{3}W$ at the third points, $M = WL/9$; for three concentrated loads of $\frac{1}{4}W$ at the quarter points, $M = WL/8$, and for four concentrated loads of $\frac{1}{5}W$ at the fifth points, $M = 3WL/25$.

Area of Cross Section in square inches of all steel sections is 0.3 weight per linear foot. (Error 2%.)

Weight in pounds per linear foot of all steel sections is $3\frac{1}{3}$ times area of cross section in square inches. (Error 2%.)

Weight of Angles—Derive the weight of an angle from the cross-sectional area of a plate having the same thickness as the angle and a width equal to the sum of the legs.

Weight of Roof Trusses—The many empirical formulas that have been given for determining the weights of roof trusses fail to take into account so many varying factors that their usefulness is very limited. It is better to make deductions from the known weights of a few trusses than from inadequate formulas. The estimated weights of a series of Fink trusses for a roof sloping 6 in. per foot, carrying a uniformly distributed load of 800 lb. per linear foot of top chord, for spans of 30, 40, 50, 60, 70 and 80 ft., are 1000, 1700, 2400, 3200, 4400 and 5600 lb., respectively. Warren trusses, for a roof sloping 1 in. per foot, and for the same load and spans, weigh approximately 1200, 1800, 2700, 3400, 4600 and 6100 lb., respectively. The weight of details in ordinary roof trusses is from one-tenth to one-sixth of the total weight. This is equivalent to an addition of from 11 to 20% to the weights of main members.

Weight of Columns is approximately weight of main material, or stem of the column, plus 20% for details. The theoretical weight per linear foot of the stem of a column in a many-storied building is approximately $\frac{\text{Load in pounds}}{12{,}000} \times \frac{10}{3}$. In determining the total weight, 25% of this should be added for details and excess of actual over theoretical section. As columns are usually fabricated in two-story lengths, the load on the lower-story portion should be used for the whole length.

Weight of Plate Girders is weight of web plate and flanges plus 20% for details. Plate girders may be approximately designed by considering the depth of web plate to be the depth of girder and neglecting the $\frac{1}{6}$ web area in proportioning the flanges.

Weights of Buildings—No reliable formula can be evolved for the weight of structural steel in buildings. Neither should the weight per square foot of area nor cubic foot of volume of a structure already built be assumed as the weight of a proposed structure, unless the conditions which govern the one are found in the other. The trusses, purlins and bracing of a roof covered with corrugated metal usually weigh from 5 to 8 lb. per square foot of ground area. In a one-story building, with both siding and covering of corrugated metal, and without traveling cranes, the weight of structural steel will average between 10 and 15 lb. per square foot. Plank, tile or concrete covering will add to this weight 2 or 3 lb. per square foot. If traveling cranes are used the weight will be increased from 2 to 5 lb. per square foot.

Floors in mill buildings vary from 10 lb. per square

foot for the floor of a light machine shop to 40 lb. for a heavy charging floor in a foundry.

Office buildings not more than 12 stories high in which the exterior walls are carried by steel framing will average about 1.9 lb. per cubic foot of volume; hotels and apartment houses about 1.5 per cubic foot of volume.

SOCIETY SERVICE

A Section Dealing with the Results of Teamwork by Technical Men

Engineers to Educate the Public

On the bottom of the stationery of the Iowa Engineering Society is the slogan "Write; talk; why not? It will help. Consult the committee on publicity." Iowa is in need of more good engineers than ever before, for she is on the eve of an immense road-building program. The society realizes that engineers in the war have made a lasting impression on the layman by doing the "far-off" task in winning the war, but real work is at hand to educate the home folk that engineering of even greater importance exists right at home.

An Example of Society Disservice

An illustration of the sort of professional friendship which engineers sometimes show to one another was recently given at Cheyenne. The Wyoming Society of Engineers, at the close of a two-day meeting, gave a dinner and held an informal meeting at the Plains Hotel on the evening of Jan. 28.

There were at the hotel at that time five engineers from various states, all of whom have been identified with Government work in Wyoming. The State Engineer, who is a prominent member of the state society, invited the visiting engineers to attend the after-dinner meeting. The invitation was later recalled, with sincere regrets on the part of the State Engineer, because some of the society members objected to having outsiders among them.

Such an incident seems incredible, but it is reported on good authority.

State Society Issues Bulletins to Members

As attendance at annual meetings of the Illinois Society of Engineers averages only 20 to 30% of the total membership, the society has issued a bulletin giving a summary of the proceedings of its recent meeting, with new officers elected, resolutions passed, etc. In this way absent members are informed as to the doings of the society. Similar bulletins are issued during the year, giving information as to the society's activities, important legislation, public meetings relative to engineering, and other matters of interest, thus keeping the members in touch with the society's work and engineering developments in general and involving no great expense. This is of particular advantage in regard to members in rural districts, who usually have little opportunity of obtaining information of this kind. As a refutation of the argument that resolutions do no good, this society has the pleasure at least of seeing some Chicago newspapers mention it as among the indorsers of the new Illinois housing bill, which aims at rigid control of future building construction.

LETTERS TO THE EDITOR

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Why Not Engineers for Federal Rural Health-Protective Work?

Sir—In your issue of Feb. 13 you review the bill introduced in Congress by Mr. Lever, to provide means for the control and mitigation of the diseases of our people living in the country and in towns of not more than 5000 persons. You say that "the United States Public Health Service is designated as the agency of the Federal Government in the work, and the states to be represented by their health department or officers." This puts the work into the hands of the doctors and absolutely cuts out the engineers, particularly in this State of New York, where engineers are not eligible as health officers. Now, the duties contemplated by this bill are such as belong to the sanitary engineer and for which very few doctors are qualified. Why is not this a case where the interests of the engineering profession should be looked after and an engineering board be made the agent of both Federal and State Governments?

H. C. HODGKINS.

Syracuse, N. Y.

Ignoring Findings of Board of Engineers on Deep Waterways

Sir—Along with many others, I am wondering why Congress is passing a bill for studies of a deep waterway canal from the Great Lakes to Atlantic tidewater, and whether it is possible that the very thorough and conclusive report in the year 1900 by the Board of Engineers on Deep Waterways between the Great Lakes is so soon forgotten. This board, authorized by Congress, had as its members C. W. Raymond, colonel of engineers; Alfred Noble and George Y. Wisner. Their study and report were an elaboration of the work of the United States Deep Waterway Commission of 1897, of which James B. Angell, John E. Russell and Lyman E. Cooley were members. The board of 1900, after thorough studies of a 21-ft. and a 30-ft. channel over various possible routes, recommended a 21-ft. canal via the Lake Ontario, Oswego, Mohawk Valley, Hudson River route, at a cost of $206,358,000.

Their advice was ignored by New York State for a barge canal limited to 12-ft. depth over the lock sills, because of the opposition of the Cities of Buffalo and New York to any canal that would give through service and thus avoid their rake-off in terminal charges. It would now seem just retribution for an economic crime if the United States should build a canal for ocean steamships to protect the Central West against this extortion mentioned in the recent debate in Congress. The New York Barge Canal, conceived with such a

purposes and in defiance of economic principle, was doomed to failure as a financial burden.

Unfortunately, it is not generally known that small oceangoing steamers have for many years been going direct to the Great Lakes up the St. Lawrence River and the Lachine and Welland Canals of Canada, in spite of the statement of Lewis Nixon, superintendent of public works for New York state, that such a route would be impracticable. This information was very definitely brought to the writer's attention in 1903 while making the preliminary engineering studies for the railroad crossing at Detroit, when a record was kept of the characteristics of all steamers using Detroit River.

Your comments on the above would undoubtedly be much appreciated. BOYD EHLE,

Tulsa, Okla. Mem. Am. Soc. C. E.

Possibilities of the Fabricated Ship

Sir—I was very much interested in the editorial on the fabricated ship printed in your issue of Feb. 20. This is timely and appropriate, and the argument is sound.

As the fabricated ship yards were built and operated under abnormal conditions, the data as to time required for assembling steel of hulls and the cost cannot be used as a basis of comparison with the records in the old, established yards. There is little doubt, however, that under normal conditions the fabricated ship will be a real competitor. While the method involves extra handling of material, this handicap should be more than offset by the advantage of quantity fabrication of each item. The great importance of this principle in shop management is well known. L. G. FISHACH.

Leetsdale, Penn.

Guarantee Profit Sharing by Law

Sir—*Engineering News-Record* at different times since the entrance of the United States into the great war has published editorials setting forth the idea that the war marked the passing of the old and the ushering in of a new order in our social relations.

There is a general call for fair dealing; a call for the employer to treat the employed as he would be treated were their positions reversed; a call for profit sharing and the apportioning of dividends.

This is good, but not sufficient. The employee should not, in so fundamental a matter, be left to the nobler sentiments or higher aspirations of his employer, be he ever so highminded, for many there are who will not be so animated. Capitalists do not so trust their wealth to other capitalists. Their every interest is safeguarded by all the legal guarantees that it has been possible for able jurists to devise.

Cannot some similar legislation be worked out to guarantee to the man in the ranks a fair share in the profits in the making of which his industry has contributed so material a part? Here is a plan, and it might be styled "An Act to Compel Profit Sharing and to Regulate the Same."

The United States Government now demands an accounting from every corporation, and appropriates to itself as "excess profits" a certain portion of the income above a stipulated return on the investment. This law might well be repealed, or amended to operate after a larger income had been allowed, and in its place legislation enacted that would demand an accounting as at present, but providing that the profits above a certain stipulated return shall be divided in a certain fixed and graduated ratio between the employer and each employee. Similar legislation would necessarily have to be enacted by the various states.

By this it is not intended that every individual who works a day here or a day there will, at the end of the year, draw "dividends" from a half dozen different concerns. That can all be regulated so that an employee will not become a "stockholder," or "member of the firm" until he shall have worked a month, or two, or three months, as experience with the plan may indicate to be best, and varied to suit different industries. At first it might possibly best be limited to manufacturing plants, continuing industries, and transportation, but as rapidly as possible it should be extended so as to include, in the end, practically all activities.

The directing of the work, except in the matter of employing and discharging men, in which a committee of the employees should have the right of review, in the future as in the past should be in the hands of the owners. Some may object to this, and argue that the employee should have a hand in the managing of affairs. As a matter of fact, he would have. For as time went on the competent employee, as opportunity offered, would withdraw his "capital"—that is, his "labor"—from the concern paying small dividends and place it with the concern paying large.

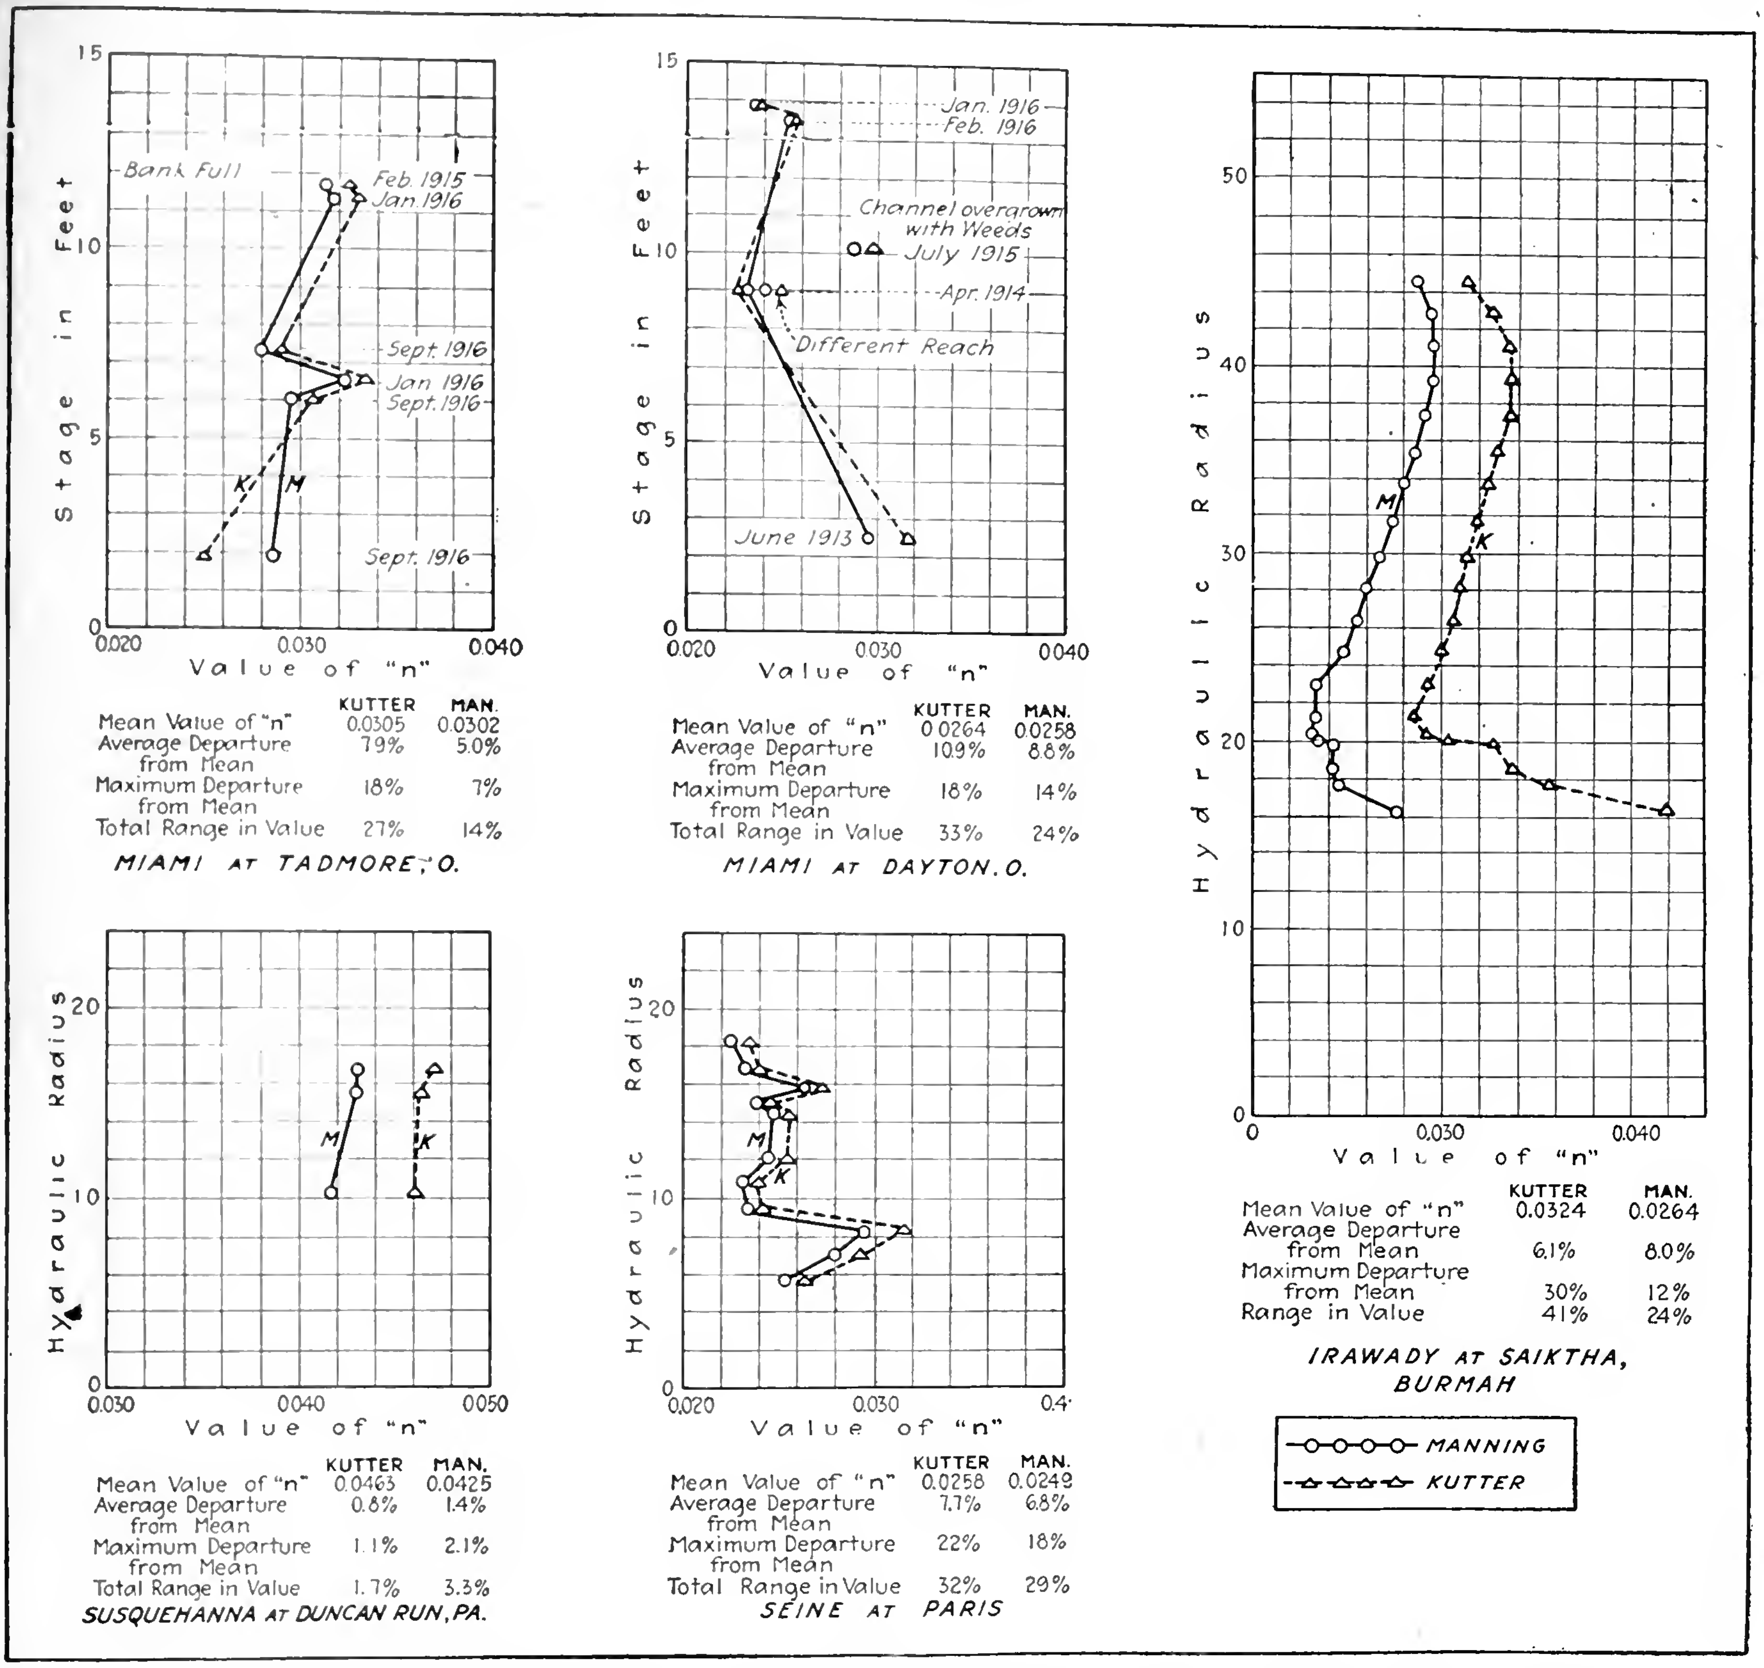
The engineers of the country represent trained intellects; to them more than to any other class has been due the wonderful progress in invention and industry, resulting in enormous increase in material wealth. With them rests in great measure the working out of measures that will make all this material progress work to the advancement of mankind. H. A. RANDS.

Portland, Ore.

Variation of Roughness Coefficient in Manning and Kutter Formulas

Sir—Robert E. Horton's review of Ivan E. Houk's excellent report on the "Calculation of Flow in Open Channels," in *Engineering News-Record* of Jan. 20, 1919, p. 149, prompts the following remarks concerning the relative variability of the roughness coefficients in the Manning and Kutter formulas. These two formulas are compared in Mr. Houk's report, and while the report is especially commendable because of the unprejudiced care with which different formulas are compared, the writer believes that Manning's formula has not received quite all of the credit to which it is entitled. The writer is strongly in favor of this formula as against the more complicated Kutter formula, not only because of its much greater simplicity, but also because the use of Kutter's n in this formula gives results practically identical in a large percentage of cases with those found by using the Kutter formula with the same value of n. This is well shown by a comparison of the two in over 250 experiments listed in King's "Handbook of Hydraulics," which Mr. Horton mentions.

In applying either of these formulas to natural streams, however, a question that has troubled the writer on several occasions is the question of the



DIAGRAMS SHOWING VARIATION OF KUTTER'S AND MANNING'S n WITH CHANGE IN RIVER STAGE

variation of n with change in the stage of the stream. Having assumed or determined by actual measurement the value of n at some given stage of a certain stream under investigation, can this same coefficient be used for others stages of the stream, and, if not, what will be the direction and probable amount of the departure from this known value? To answer this question in a small way, the writer plotted corresponding values of Kutter's n and Manning's n for various stages for a few of the streams on which the experimental data cover a fairly wide range in stage. The few examples presented above do not include all of the available material by any means, although it may be noted in this connection that experiments on natural channels which cover a large range in stage are not plentiful. Of those which do exist, not all can be used, because some minor change in conditions during the series introduces a disturbing factor which renders comparison of the different experiments uncertain.

The five examples given cover a wide range in natural channel conditions. Of these the series on the Miami River at Tadmore seem to the writer to deserve the greatest weight. Conditions on the reach selected were very favorable to good results, and the work appears to have been carefully done in all respects. The experiments cover the entire range from low water to bank-full stage. Zero of the gage is apparently about a foot above the stage of no flow. The work on the same stream at Dayton does not seem to have been done under such favorable circumstances, as the condition of the channel was not the same in all experiments. These experiments do not cover such a wide range in stage as those at Tadmore. Zero of the gage is probably about 5 ft. above the stage of no flow, while bank-full stage is given as 18.0 in the Weather Bureau description of the gage. In the other three examples given, it was necessary to plot n against the hydraulic radius, as the stage was not given. This,

however, closely indicates the change with stage. The Susquehanna experiments made at McCall's Ferry by Anderson, when compared with the Miami work, are only fair. The fourth experiment was not plotted, as a different section from that used in the first three was taken. The Irawady and Seine experiments are taken from Hering and Trautwine's translation of Kutter and are given because of the wide range in the value of r which the experiments cover. The original data on these experiments were not available to the writer, and therefore he could not form a personal opinion as to their relative weight. He well recognizes the danger of blindly presenting data without a careful examination of the original material, for often in abridging experiments for quotation the facts essential to a proper comparison of the experiments are of necessity omitted.

In referring to the diagrams, it should be noted that the lines joining the plotted points are for the purpose of bringing out their relationship, and they do not indicate values of n for intermediate stages between the points. The variability in each series is shown by the maximum, average, and range of departure of the individual points from the mean value for the series. These are expressed as a percentage of the mean value.

The results on the diagrams indicate—at least for these few streams—a greater stability on the part of Manning's n than is shown in Kutter's. It shows less variation as the stage changes and can, therefore, be used with greater reliance over a range of stage. Needless to say, the coefficient which comes the nearest to remaining constant over a range of stage is the more desirable, and Manning's n shows this property to a greater extent than Kutter's. Aside from the question of variation, it will be seen that the absolute values of the two n's are not widely different, both lying within the range of values commonly considered in connection with natural streams. The random assumption of some value of n for a given stream is at best subject to more or less doubt. A single experiment on the stream is much to be preferred, and the data obtained in this way is as easily reduced to Manning's as to Kutter's n. The engineer then has a coefficient which he can apply with greater assurance to a greater range in stage than he would be justified in doing with Kutter's n. H. R. LEACH.

Saginaw, Mich.

[On Mr. Leach's comments Mr. Horton writes as follows:—EDITOR.]

Sir—Mr. Leach calls attention to an important matter in relation to river hydraulics.

While his conclusion is undoubtedly correct, that the formula which gives the least variation of coefficient with varying stage is, other things being equal, the one to be preferred, yet it seems desirable to go a little farther and call attention to the fact that the coefficient of roughness in these and other similar formulas includes some things beside the effect of roughness itself.

The coefficient of roughness as ordinarily determined, especially in the case of low water on streams, includes ineffective fall and ineffective cross-section as well as roughness. At flood stages of a stream, practically the total fall and the total cross-section in a stream of even quite irregular channel width and depth are effective in producing velocity and transporting water. At low stages a considerable part of the fall may be lost in ripples and eddies, and if there are deep pools, numerous bends or wide shallow reaches there may be stagnant water, and the portion of the cross-section which it occupies, if included in the measured cross-sections used in calculating the coefficient of roughness, will result in an apparent coefficient of roughness larger than that for the same stream at higher stages.

The writer has seen instances where the banks of a stream were unquestionably rougher than the bed, and yet the coefficient of roughness almost invariably decreased as the stream stage increased, the coefficient being calculated, as is the usual practice, from the actual cross-section and measured slope, whether effective or not. This simply emphasizes the fact that slope formulas, like most other engineering methods, are neither automatic in their operation nor fool-proof.

In general, if a coefficient of roughness has been determined at a certain stage of a stream, its value should be somewhat decreased when applied to higher stages, and increased when applied to lower stages.

Mr. Leach's letter gives some valuable information indicative of the character and amount of the change in coefficient of roughness with changing stage.

Albany, N. Y. ROBERT E. HORTON.

Utilize the Topical Index for Reference

Sir—Your average reader probably observes the topical index on the front page for the purpose of noting the articles pertinent to his particular line of work, and then forgets it. It has been my practice to utilize this topical index in a very concrete manner by clipping the items in which I am more particularly interested, and pasting the same on a 3 x 5 card. This card is filed in a suitable card index file, which is kept on my desk for immediate reference. After the article is read carefully it is readily referred to at any future time by inspection of my card index.

In this manner I have a working index to the live articles published weekly in *Engineering News-Record*, and it is not a study to remember where and in which number a desired article is published.

F. L. BIXBY,
Reno, Nev. Senior Irrigation Engineer.

Locations for Improved Public Highways

Sir—From *Engineering News-Record* of Dec. 19, 1918, just received, I am pleased to learn of the extensive interest being shown in the United States in permanent good roads.

Having had many years of road experience both as engineer and contractor in New York State and New England, in addition to nearly a year of road work with the A. E. F., I venture to suggest that when permanent roads are constructed they be built on permanent locations. By permanent locations I mean those that will not necessitate change through any condition now foreseen. Make the location as well as the road surface permanent.

Trucks will be the most important users of good highways. Experience here and elsewhere has proved to my satisfaction that grades requiring a loaded truck to go into intermediate gear, or curves that require a material reduction of speed, are much more serious matters than I had previously believed. The capacity of an otherwise good road under heavy summer traffic

is materially decreased by even one grade requiring the use of intermediate gear, and that capacity suffers a further very material decrease during periods when snow and ice are encountered.

Location is part of the road, and a good location is an absolute necessity in order to get 100% efficiency from any given road surface. The better the surface, the more important the location. The saving in maintenance charges by a proper location, together with the saving in operating expenses of motor vehicles, will be of benefit to all generations, including the present, which must soon decide the question of permanent locations. The cost of a proper location is as proper a charge against the total cost of a permanent highway as the cost of right-of-way is against the cost of a railroad.

I believe that in many cases it is not economy to build a modern permanent road on a location made years ago under entirely different conditions. Railroad engineers have shown the wisdom and economy of expending large sums of money in order to obtain better locations. With the advent of the large, heavily loaded motor truck, the principles controlling highway and railroad location have become more closely associated, and the principles governing railroad location should be more closely followed.

HORATIO L. BAKER,
First Lieutenant, D Company, Twenty-third Engineers.
U. S. A., P. O. 903, American Expeditionary Forces.

Correction of Level Notes for Personal Equation and Other Errors

Sir—The writer had occasion last summer to work out a method of eliminating errors and personal equations in leveling which, to the best of his belief, is new and most promising. It is as follows:

In adding to the distribution system served by the Elephant Butte dam below El Paso, Tex., under the United States Reclamation Service, topography was to be taken over a strip of valley some 45 miles long. A transit control line was run, and at every sixth station a special hub was set for a benchmark. Levels were then run on these hubs, with readings to thousandths, by three level parties, working one after the other but absolutely independently. Set-ups were made at the station stake midway between the hubs, thus eliminating instrumental errors as much as possible. The three chiefs of party were not allowed to compare notes on elevations.

When the results came in, the values of the final point all checked within a foot, and considerable discussion ensued as to the proper method of evaluating them. The first levelman was a very experienced man, while the second and third were much younger, one being still graded as a rodman. The tendency of the office force was to discard the results of the two less experienced men, but the writer argued against this and won.

In order to present the matter graphically, as the chief had to be "shown" and his time was limited, the writer devised this scheme: Upon a sheet of profile paper were plotted the differences between each pair of notes for each hub. Thus, if the three sets of levels are designated A, B and C, at each point A-B, B-C and A-C were plotted, and all A-B values joined, etc. If for a given point A gave 3597.077, B gave 3597.032 and C 3597.859, A-B was plotted at plus 0.045, A-C at minus 0.782 and B-C at minus 0.827, care being taken to observe algebraic signs. These points were then joined with the corresponding points for the preceding hub, which were plotted on the preceding vertical subdivision. The result was three surprisingly regular curves, often crossing and recrossing the zero line, and with a few noticeable irregularities. These breaks, of course, were the significant features and were investigated carefully. Where all lines were running comparatively parallel and two lines dropped or rose over a certain hub and returned to the former relative positions at the next hub, it indicated a disturbed point, or dirt on the hub. However, if the two lines, after jumping, failed to return but continued parallel to the previous course an error in rod reading was thereby indicated in the set of notes common to the two lines, and the amount was evident.

Thus, if B-C and A-C lines jumped two hundredths at one hub and continued parallel afterward, it showed that C was out two hundredths from that point on. The scale was made such that thousandths were easily read. Numerous errors were detected in this way, and the notes of each party were corrected accordingly and the differential values once more plotted. This last plat showed one set of levels to be less reliable, as two of the lines were quite irregular, while the third ran smoothly throughout. The two sets of notes represented by the third line were then averaged, and the values obtained tabulated for permanent use.

A curious feature aroused some discussion regarding the third, or smoothest, curve. The digressions from the zero line were regular, nearly equal, and recurred at strikingly regular intervals, almost following a sine curve. The most plausible theory advanced to explain this was that the parties did not work at the same speed, one being noticeably slower. Therefore, one stretch would be traversed by both at the same time of day on different days, and other stretches would be covered by one party in the morning of a certain day and by the other in the afternoon. Since the daily range of temperature was high at that time, it is thought that the increased mutual discrepancies occurred at points where readings were made at opposite hours of the day, and were due to expansion and contraction of the earth's crust during the day.

It also appeared that the more experienced levelman had fully his share of errors in rod readings, while the "greenest" man had the least, showing that results should not be entirely discarded, no matter what the ability of the observer. Also, the use of the third set enabled the writer to place each error positively and correct it without another trip in the field.

All persons who inspected the curves and the results agreed that the method was novel and extremely useful, as the "why and wherefore" of all corrections was seen at a glance. I trust others may find its use convenient.

The work in question was done in connection with the Fort Hancock survey, in August, 1918, under Assistant Engineer J. G. Marzel, of the Clint, Tex., office, where the writer was chief of party acting as office engineer.

RUSSELL A. TRUFANT,
American Rio Grande Land & Irrigation Company.
Mercedes, Tex.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Side Chute Charges Wheelbarrows From Cement Wagon

BULK cement hauled in wagons and unloaded by detachable measuring chutes from the wagons to the charging barrows was used in paving 7000 ft. of Main St., North Chicago, Ill. Ten carloads, or 3000 bbl., of cement were handled, and the contractors, the James Cape & Sons Co., Racine, Wis., state that they intend to use bulk cement on all future contracts where the consumption exceeds 150 bbl. per day. The haul from the railway to the work was about one mile. Three wagons, which were equipped with 20-bbl. metal-lined grain boxes, were routed so that one wagon was at the car taking its load, one was en route between the car and the work and the third was at the work discharging its load. One team did the hauling. An average of eight wagon loads per nine-hour day was hauled.

Other Articles in This Issue of Interest to Contractors:

MEASURING CHUTE ON WAGON CHARGES BULK CEMENT INTO BARROWS

At the car, the cement near the door was shoveled directly into the wagon. When enough cement had been removed to make the distance too great for shoveling, wheelbarrows were used. A steel plate bridge from car to wagon permitted the barrows to be dumped directly into the wagon. One man did the unloading. At the work, the chute was hooked into the wagon body and one man did the unloading. The chute was a broad box 24 in. high and 12 in. square, with a hopper 18 in. high and 24 in. square at the top. A slide gate at the bottom of the chute and another at the bottom of the hopper made the chute a measuring box of 2-cu.ft. capacity. The hopper, level full, also held 2 cu.ft. By alternately opening and closing the slide gates, wheelbarrows were charged with 2-cu.ft. batches of cement, and were then wheeled to the mixer and dumped directly into the charging skip. One or two men did the wheeling.

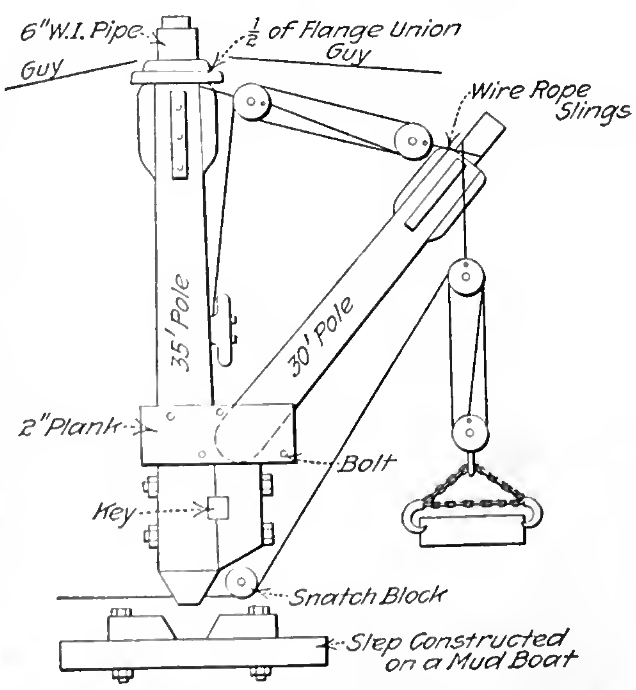
Canvas covers for the wagons prevented any loss of cement from rain.

Improvised Derrick Without Usual Irons

BY SAMUEL P. BAIRD

Columbus, Ohio

THE accompanying figure illustrates an improvised boom derrick, built without the derrick irons which would ordinarily be thought necessary. The principal features are the step-bearing for the mast, the step for the boom and the means for allowing the mast to rotate at the top. The rope used was 1-in. manila, the boom hoist was a pair of double blocks, and the main hoist was a combination of a double and a triple

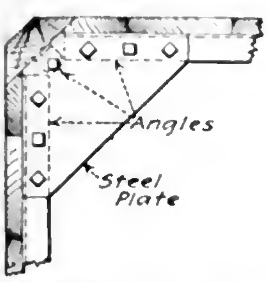


NO DERRICK IRONS USED IN THIS HASTILY IMPROVISED RIGGING

block. The main power was a steadily moving team. The loads lifted were stone weighing about a ton, and they were raised high enough for a truck to back under. A friction drag was provided on the main fall line, to lower the load and to allow the team to return as soon as the load was raised to the desired height.

Rigid Corner Frame Permits Frequent Re-use of Concrete Forms

REMOVABLE corners for concrete forms, such as the one described in *Engineering News-Record* of Jan. 23, 1919, p. 203, have been used for some time by E. H. Oneal, of Globe, Ariz. A special type for shaft concreting is shown in the accompanying sketch. It consists of a drilled and shaped steel corner plate to which are bolted angles carrying the side planks of the form and a special corner piece. While the cost of the individual forms was high, the cost per unit of conrete was low because the forms could be used over so many times. Some were re-used 26 times and were still in good condition. To strip such a form, the bolts are unscrewed and the separate plank sections lifted out.

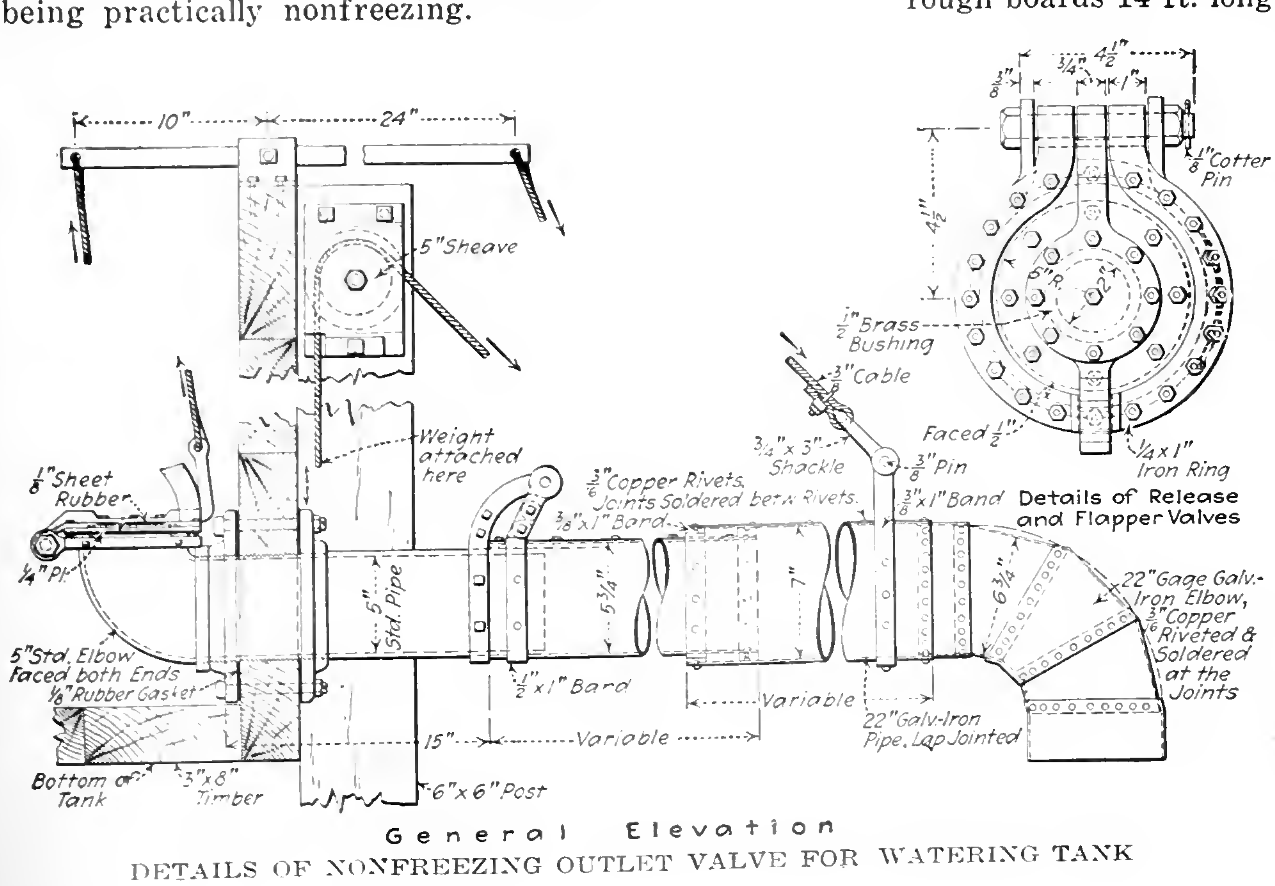


CORNER BRACE FOR CONCRETE FORM

Economical Nonfreezing Type of Outlet Valve

By John H. Sawkins
Instructor in Drawing, Civil Engineering Department, Union College, Schenectady, N. Y.

AN OUTLET valve suitable for temporary watering tanks, such as are used by contractors for watering dinkies on filling and excavation contracts, is shown herewith. The advantages of this type are: (1) It can be made at small cost, using standard pipe fittings and other material commonly found in any small machine shop; (2) it is simple both in construction and operation; (3) it is especially adapted to winter work, being practically nonfreezing.



DETAILS OF NONFREEZING OUTLET VALVE FOR WATERING TANK

As indicated in the drawing, the valve consists essentially of a standard cast-iron elbow, two cast-iron pipe flanges and a short length of common pipe. The detail drawing of the combined release and flapper valves shows clearly that all the component parts are simple pieces easily made, standard bolts being used for connecting the pieces. It is recommended that a good grade of sheet rubber be used for facing the plates, and that the elbow be faced very carefully on a ring ½ in. wide, in order to secure a water-tight connection between it and the rubber, thus avoiding undue leakage of water, which may cause the valve to freeze. The same applies to the connection between the rubber and the brass brushing.

The operating device is especially made to withstand rough usage usually given by firemen who operate such valves, simplicity in both design and operation being the feature sought. The valve is particularly designed to adapt it to winter conditions, since much trouble has been caused to contractors in obtaining an outlet valve servicable under all weather conditions.

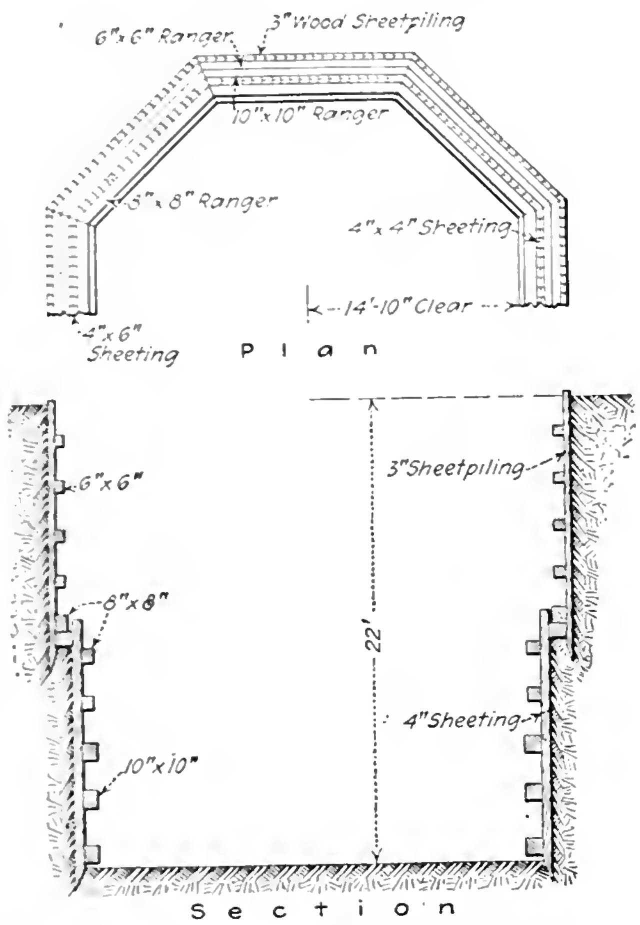
The location of the valve as shown in the general assembly view offers least chance for trouble due to freezing if the tank is at all times kept nearly full of water.

Bracing Eliminated in Sheeting Octagonal Excavation

By W. K. Knauff
Supervising Construction Engineer, Delaware City, Del.

IN ORDER to keep the excavation for a sewage pumping station at Fort du Pont, Delaware, unencumbered with braces during concreting, the layout of the sheeting as a regular octagon with mitred rangers was designed. Rangers of various sizes formed a complete octagonal ring, the rangers butting into each other at the corners with a miter cut. Vertical blocks, two to each side, supported each set of rangers from the one below, and no other bracing was employed.

The first set of sheeting was made up of 3 x 6-in. rough boards 14 ft. long, spiked together three to a pile, and arranged to give a 2-in. tongue-and-groove. A plank templet was made with inside dimensions equal to the outside dimensions of the excavation, and eight special corner piles were made up and started, one at each corner of the octagon. The flat sheeting was then placed to complete the sides. As the excavation progressed, 6 x 6-in. oak rangers were placed about 2 ft. 6 in. on center, the joint between the first and eighth sides being made by raising these pieces sufficiently to bring the lower edges of the miter together, and then forcing them back to the horizontal by jack screws. In this way each set was brought to a



EXCAVATION KEPT CLEAR BY OCTAGONAL LAYOUT

firm bearing against the sheeting itself. At about 8 ft. the sheeting could not be driven more than a foot below the lowest set of rangers without curling badly and having to be cut off on account of lack of stiffness. The trouble was overcome by making a ring of 8 x 8-in. timbers and jacking it down as the excavation progressed. The upper set of sheeting was carried to a depth of 12 ft., a set of 10 x 10-in. rangers being placed near the bottom and used as a templet by the lower set of sheeting.

The lower sheeting was composed of 4 x 6-in. yellow pine, 12 ft. long, tongued and grooved and center matched, the eight corner pieces being made up and spiked together as before. The rangers were made in complete rings, two sets of 8 x 8-in. timbers and two sets of 10 x 10-in. One set of 10 x 10-in. timbers was jacked down as the excavation progressed, to keep the sides from curling in, because even the 4 x 6-in. sheeting was not stiff enough to resist the side pressure. This set of sheeting was carried down to the bottom of the excavation about 22 ft. below the surface of the ground.

The site of the excavation was in low-lying ground near a marsh, and the excavated material was fine mica sand, water having been encountered about a foot below the surface. Although at times the pumping capacity of the plant was taxed to keep the water low enough for the men to work, comparatively little difficulty was experienced in the wash around the timbering. The excavated material was handled by a small derrick operated by a 12-hp. gasoline hoist. The sheet piling was driven by a 4-in. McKiernan-Terry sheeting hammer. The scheme was devised to enable the work to be carried on with as little delay as possible, utilizing the equipment and material available locally, sheet-steel piling and an orange-peel excavator not being procurable except at the cost of considerable delay.

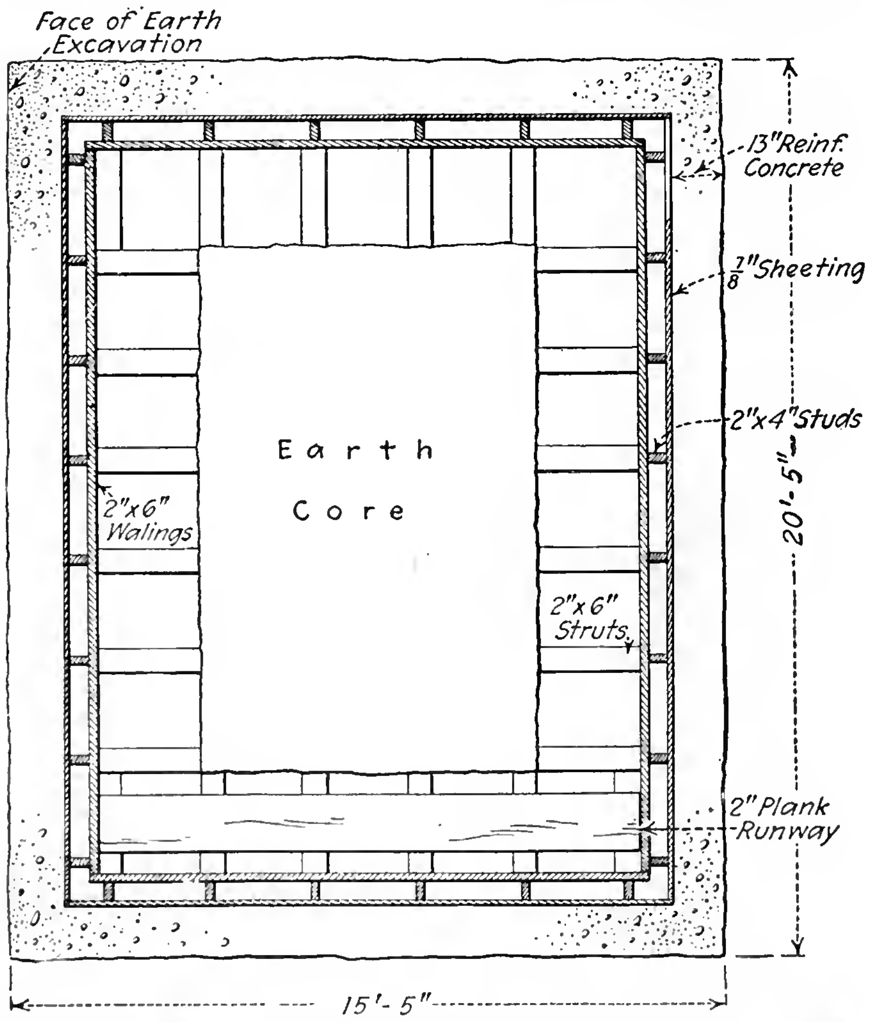
The work was performed by R. G. Collins, Jr., general contractor, under the direction of Capt. J. A. Sears, constructing quartermaster, U. S. A., with the writer as supervising construction engineer.

Concrete Walls Poured Before Core is Excavated

By D. H. Fleming

Assistant to City Engineer, St. Catharines, Ontario, Can.

A RECENT Canadian contract called for the excavation of a pit 15 x 20 ft. in section and 30 ft. deep, and the construction of reinforced-concrete walls, etc. The material encountered was a hard, tough clay and the contractor excavated a trench about 4 ft. wide around the outside, in much the same manner as for a sewer trench. The reinforcement was then tied in place and inside forms were erected in 4-ft. lifts, constituting a day's work. After the concrete walls were poured and the forms taken out, the earth core was excavated. This



30-FOOT PUMP WALL SHOWING CORE SUPPORTING FORMS

method enabled the contractor to save the expense of large timbering, which would have been required for struts or props. It aided in the protection of the concrete from freezing and enabled the contractor to pour the concrete during a spell of good weather, leaving the excavation work to be done later.

Seattle Plans for Reconstruction

Reconstruction questions of the City of Seattle, Wash., and King County are to be considered by a large commission which has been appointed by Mayor Hansen and which will coöperate with similar commissions throughout the state. In addition, the authorities are planning to commence work on a water-supply extension to cost nearly $4,000,000, a hydro-electric plant to cost $5,500,000, and street and sewer work totaling about $3,000,000.

NEWS OF THE WEEK

New York, March 13, 1919

Price Stabilization Board Appointed

Action on Secretary Redfield's plan for a stabilization of prices by co-operation between the producer and the Government has been started by the appointment of the members of the Industrial Board of the Department of Commerce, which, with the Council of National Defense, will act for the Government. The chairman of the board is George N. Peek, of Moline, Ill., formerly with the War Industries Board and vice-president of Deere & Co. The other members are Samuel P. Bush, Columbus, Ohio, president of the Buckeye Steel Castings Co.; Anthony Caminetti, Washington, D. C., commissioner general of immigration, Department of Labor; Thomas K. Glenn, Atlanta, Ga., president of the Atlantic Steel Co.; George R. James, Memphis, Tenn., president of the William R. Moore Dry Goods Co.; T. C. Powell, Cincinnati, Ohio, director of the Capital Expenditures Committee, United States Railroad Administration.

The board expects to begin immediately conferences with representatives of various basic industries, in the hope of establishing the lowest possible prices which can be offered at present. Government buying will then be made on the basis of such prices, which will not be fixed, as during the war, but will be given wide publicity for the information of the private buyer. The producer, of course, will not be forced to accept any such established price, but it is hoped that the weight of the Government statement of a fair price will serve to establish such a standard.

American Mayors' League Proposed

Immediately after the recent Governors' and mayors' conference in Washington, a number of the mayors present met and unanimously voted to recommend to all mayors of cities of 25,000 population or over the formation of a permanent organization which may perhaps become known as the American Mayors' League. A resolution was passed requesting the Secretary of Labor to call such a conference not later than Feb. 1, 1920. The opinion of all present was that there should not be over one set speech each day of a conference extending to at least four days. It was also voted that Congress be asked to adjourn at least one day during the conference, and hear the report which the mayors might have to offer. The following committee was appointed to take all matters concerned into consideration and report: Chairman, George L, Baker, mayor of Portland, Ore.; secretary, R. W. Babson, Boston; together with F. W. Donnelly, Trenton, N. J., W. Montague Ferry, Salt Lake City, Daniel W. Hoan, Milwaukee, Wis., and R. J. Wheeler, Allentown, Penn.

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Professional and Special Section, United States Employment Service; Thomas T. Read, manager Eastern zone, 16 East 42nd St., New York, and Ward R. Robinson, manager, Central and Western Zone, 63 E. Adams St., Chicago.

1518 Walnut St., Philadelphia.

16 Tremont St., Boston.

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

American Association of Engineers, F. H. Myers, manager, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Penalty for Municipal Strikers

Loss of annual vacation has been imposed as penalty on city employees of Seattle who joined the recent general strike in that city. In addition, 15 days' pay will be withheld from those who did not respond to Mayor Hanson's demand that they return to work. A request of the Central Labor Union to rescind this ruling has been denied

Commissioner of Public Works for Oregon

In connection with a proposed $3,000,000 reconstruction bond issue to be used for public buildings and a $1,235,000 appropriation for new buildings, alterations and repairs authorized by the recent session of the Oregon legislature, provision has been made for the office of commissioner of public works. The commissioner will be under the direct supervision of the State Board of Control, which has charge of state construction work.

Proposes Rapid Transit Viaduct Across New York Bay

Rapid-transit connection of Staten Island with the main business district of New York City, brought to the fore recently by suggestions to begin the construction of the long-contemplated extension of the Brooklyn Fourth Ave. subway to Staten Island by a tunnel under the Narrows, is the subject of a remarkable alternative project submitted to the Staten Island Subway Committee recently by S. Johannesson, a New York engineer.

This project contemplates a viaduct railway crossing New York Bay from Ellis Island to Staten Island, a distance of about 22,000 ft., supplemented by a tunnel about 7500 ft. long from the Battery, Manhattan, to Ellis Island. The entire line is estimated to cost about $18,000,000.

Course of Proposed Structure

Passenger and wagon connection between Manhattan and Staten Island is made at present by a line of ferry boats running from South Ferry, Manhattan, to St. George, Staten Island, a distance of five miles. The proposed structure would parallel the course of these boats a short distance to the west, being laid close along the established pierhead line on the New Jersey shore, off Bayonne, for the entire distance south of Ellis Island. It is intended to adapt the structure to the necessary future development of this riparian district for steamship service, by placing the supports of the viaduct so that they would come within the pier areas, the spans crossing the slips between piers and giving unencumbered passage to vessels. For the present design a slip width of 300 ft. and a pier width of 150 ft. have been used, and the structure as designed consists of a series of steel arch spans across the slips, shaped so as to give a full)0-ft. clearance height for the entire width of the slip, and connected by girder spans over the piers, these spans preferably to be masked by stone or concrete face walls. At the south end of the line, where the route crosses the Kill von Kull, the entrance to Newark Bay and Staten Island Sound, a clearance height of at least 140 ft. will be required, and here two 500-ft. spans across the channel are provided. The water and ground conditions over the entire length of the viaduct are favorable, it is asserted, the water depth varying from 5 to 20 ft., and rock being found at relatively shallow depth. The tunnel under the Hudson River from the Battery to Ellis Island would have

to deal with a maximum channel depth of something over 50 ft. At its southerly end it would rise on a 3% grade to the Ellis Island portal.

Great saving of transportation time as compared with the route through Brooklyn is claimed for this project. Furthermore, as the Fourth Ave. subway is largely taken up with Brooklyn traffic, only a small margin of capacity is available for through traffic to Staten Island, whereas it is asserted that the bridge route would provide all needed capacity. The structure as designed, and the estimate above quoted, contemplates a two-track railway and a two-line vehicle roadway.

Why More Catskill Water is Needed by New York City

Rainfall of but 43 in., compared with 47 in. as the average on the Catskill drainage area for the past 13 years, and a large use of Catskill aqueduct water to save pumping for Brooklyn Borough, had drawn down Ashokan reservoir storage to 56,000,000,000 gal. and Kensico reservoir storage to 17,000,000,000 gal. Mar. 1, according to information from the engineering department of the Board of Water Supply, New York City.

The maximum capacity of these reservoirs is 128,000,000,000 and 29,000,000,000 gal., respectively. The safe daily capacity of the area tributary to the Ashokan reservoir is 250,000,000 gal., but for more than a year the reservoir has been delivering 380,000,000 gal. a day and the city has been using 430,000,000 gal. daily from the Catskill supply. The excess of use over Ashokan reservoir delivery has been made up of 30,000,000 gal. a day drawn from storage in the Kensico reservoir and 20,000,000 gal. from area tributary to Kensico. Indications are that pumping may again be necessary to supply Brooklyn. There is no danger of a water shortage, it is said, as the Croton reservoirs are about full, but Catskill water can be delivered so as to avoid pumping. Already some $2,000,000 of pumping costs have been saved by the Catskill gravity supply.

The Board of Water Supply is now building the Shandaken tunnel, which will divert water from the Schoharie drainage area to the Ashokan reservoir and make possible a delivery of 500,000,000 gal. a day through the Catskill aqueduct. The tunnel is 18 miles long and will not be completed for some five years. Plans are being made for a dam at Gilboa to store Schoharie water, and it is hoped that its construction can soon be undertaken, both as an essential part of the Catskill supply and to help furnish employment. The cost of pumping the 250,000,000 gal. a day which the Schoharie will yield would be about $2,000,000 a year. The entire estimated cost of the Schoharie project is $22,175,000. J. Waldo Smith is chief engineer and Thaddeus Merriman is deputy chief engineer of the Board of Water Supply.

Hurley Reports on Cancellations of Ship Orders

In a statement to the chairman of the House Appropriations Committee, E. N. Hurley, chairman of the Shipping Board, has given the first definite facts on the cancellations of ship orders by the Emergency Fleet Corporation. In this statement he says that up to Jan. 1, 1919, contracts for 107 ships (55 steel, 32 wood, and 20 concrete) had been suspended or canceled. Up to Feb. 15, 1919, the cancellations and suspensions had increased to 550 vessels, most of them steel. The total represents about 2,700,000 dead-weight tons carrying capacity, and over $400,000,000 in cost.

Present construction by the Emergency Fleet Corporation totals roughly 10,000,000 dead-weight tons. This, with foreign construction, is expected to produce by 1921 a world's fleet about 5,000,000 tons ahead of that of 1914. With respect to further cancellations, Mr. Hurley stated: "We are already presented with heavy claims for damages as the result of the cancellations we have already made. To make many more would . . . . disturb the labor conditions of the country . . . . cause failures in the shipbuilding trade . . . . destroy the fortunes of people who have invested in these industries." And he advised against attempting to cancel more contracts.

Report on Federal-Aid Highways Misleading

Federal-aid highways to the amount of 793 miles, instead of 45 miles as indicated by a recent report of the Department of Labor, have been constructed, according to a statement of P. St. J. Wilson, acting director of the Bureau of Public Roads. The Department of Labor apparently only considered completed and accepted projects instead of completed miles of highway. Inasmuch as over $2,000,000 had been paid to the states, and as the reported condition was being used as an argument against further appropriations for this purpose by Congress, Mr. Wilson prepared for publication a report of which a part follows:

"Of the appropriations made by the Federal-aid road act, as approved July 11, 1916, $30,000,000 is now available and $20,000,000 additional will become available July 1, 1919, which amounts, less the 3% deducted for administration, have been apportioned among the states. To Jan. 31, 1919, projects had been approved involving a total of 8903 miles of road and $23,526,102 of Federal aid. Of this mileage, notwithstanding war conditions and the restrictions necessarily resulting therefrom, the equivalent of 793 miles had been completed on the above date, requiring an expenditure of about $2,096,000 of Federal funds. Of the mileage represented in approved projects, there remain yet to be constructed about 8110 miles, which will involve about $21,430,102 of Federal funds. The indications are that an immense amount of construction work, both delayed and new projects, will be undertaken during the 1919 construction season."

Reports received by the bureau indicate that $385,000,000 will be spent for roads and bridges during the coming season in the United States, and the new Federal-aid appropriations approved by Congress, if utilized by the states, will add several million dollars to this sum.

Oregon Reconstruction Bond Issue

The legislature of Oregon has passed a bill providing for a $3,000,000 reconstruction bond issue, subject to popular approval at an election to be held June 3. The money will be used for various public buildings, including $500,000 for a new penitentiary, $350,000 for a reconstruction hospital with a possible expenditure of $500,000 under certain contingencies, and $500,000 for buildings at Corvallis for the Oregon Agricultural College, and another $500,000 for buildings at Eugene for the University of Oregon, the college work to be carried out jointly by the regents of the two institutions.

Improve Kansas City Water-Works

Improvements to the water-works of Kansas City, Mo., interrupted by the war, will be put under way at once, according to information from W. G. Goodwin, chief engineer and superintendent. The city expects to advertise within two or three weeks for bids for a 16,000,000-gal., reinforced-concrete reservoir. A contract for the excavation for this work has already been let. Plans are being prepared for a new high-service pumping station. Bids will soon be advertised for a 50,000,000-gal. low-service pump. A 20,000,000-gal. high-service steam turbine pump for the new station has already been contracted for. Possibly the low-service station will be moved to the Missouri side of the river. It is hoped that filtration will be taken up in the near future. Water-works improvement bonds to the amount of $1,500,000 were authorized about a year ago.

Professional Employment Service Opens New Offices

In order better to place the many returning Army officers in suitable business positions, the United States Employment Service has opened two zone offices in addition to the main ones in New York and Chicago. Besides the two just ready for business at 1518 Walnut St., Philadelphia, and 16 Tremont St., Boston, other offices will be opened soon, each to serve the particular zone in which it is located.

Applicants are required to make out detailed statements of experience and are personally interviewed, in order to determine just what work they are best fitted for. Likewise, employers are requested to be as specific as possible regarding their requirements.

Every soldier—officer or private—on leaving the Army is reminded that the Employment Service stands ready to help him hunt a job, and a surprisingly large number are taking advantage of the offer. Employers who desire to build up their organizations with discharged officers are requested by the Employment Service to get in touch with the nearest Professional and Special Section office.

Propose Conference on Column Formula and Train Loading

Appointment of a conference committee of the American Society of Civil Engineers, to obtain joint action on a column formula and a standard train loading for use in bridge design, was proposed at the meeting of the society Mar. 5. The American Railway Engineering Association has under consideration revised specifications for railway bridges, which contain a column formula of the parabolic type, a form hitherto not used in bridge or structural practice in this country. In view of this, C. E. Fowler moved that the Board of Direction of the society appoint a committee to confer with the association "in regard to delaying the adoption of the proposed column formula, which is somewhat revolutionary in character." The same committee is to attempt to secure agreement on a new train loading for bridge design, in place of the Cooper loading now widely used and adopted also in the new specifications. J. E. Greiner seconded the motion, which was passed by the meeting.

New State Highway Commissioner Nominated in New York

Governor Smith of New York has sent to the Senate the nomination of Col. Frederick Stuart Greene of Sands Point as state Commissioner of Highways to succeed Edwin Duffey, who was appointed during Governor Whitman's administration.

Goethals Retires to Civil Life

Maj. Gen. George W. Goethals, director of purchase, storage and traffic, General Staff, U. S. A., has retired to civil life. In a letter to General Goethals, made public by the War Department, Secretary Baker says:

"The success of your work is manifest, and I have no doubt when the history of this great undertaking comes to be written, your contribution to the success of the country in the war will be an outstanding feature."

Will Be Renamed Newlands Project

The Truckee-Carson irrigation project in Nevada, it is announced by Secretary Lane, will be known hereafter as the Newlands project, in commemoration of the late Senator Francis G. Newlands, who was the father of the reclamation law.

Notes from the Field

Confidence is one of the necessary ingredients for sustained relations between buyer and seller. So, too, is it a condition for lasting industrial peace. That such peace is not impossible of attainment is shown by the following story, told by an engineer who adjusted labor controversies during the war. When trouble impended he put the determination of the proper wage up to a single individual—sometimes a manager, sometimes an employee. Invariably both sides were satisfied with the award.

The selection of the man in whom implicit confidence could be placed was made in a variety of ways. Sometimes a labor leader would suggest the right man, at other times a banker, another employer, or some citizen whom the adjuster could trust. It so happened that a manager was selected quite as often as a worker. The critical point was to get a man who knew the situation and could be trusted. The procedure was something like this:

The individual chosen would be invited to the adjuster's hotel. "I'm told," the adjuster would begin, "that you are perfectly square and that I can rely on you to deal honestly with me and with the Government. Forget now that you are an employer [if such were the case] and consider yourself just a patriotic American, trying to help win the war. The employees demand 75c. an hour. You and your fellow employers are standing for 60c. I want you to write down the proper scale. Whatever you write, I'll approve. In other words, you, acting for the Government, must determine the award in this dispute. You know the whole situation. I do not. I'm acting in this way because So-and-so has told me that you are square, that you will not "double-cross" me and the Government.

Invariably there was a refusal, the individual protesting that he could not depart from the figure his confreres were fighting for. In the end, though, the adjuster's appeal would win, and only in one instance did the selected individual, by setting the wrong figure, betray the confidence that had been reposed in him.

But the important part of the story is this—that if the new scale had been set by a labor representative, the employers invariably wanted to know by what process the adjuster had been able to hit on just the right figure, while if a manager had set the wage for settlement, labor was mystified as to the process by which the right figure had been reached. In other words, both sides knew what was right. Traditional antagonism and hope that by strike one of them might gain an advantage or additional concessions kept them apart.

Had there been confidence that both parties would be fair, the mediation of the adjuster would not have been needed.

The great industrial problem is to establish this confidence. E. J. M.

West Virginia Legislature Votes Large Highway Bond Issue

After a vigorous campaign, the West Virginia legislature has adopted unanimously an amendment to the constitution, providing for a definite system of state roads and for the issuance of $50,000,000 of state bonds, outstanding at any one time, for highway construction and maintenance. At the same time the legislature passed unanimously a provision reëstablishing the road school at the state university. The system as proposed will connect the various county seats.

Form American Welding Society

The formation of the American Welding Society is announced in a recent statement from H. C. Forbes, secretary of the temporary organization, at 29 W. 39th St., New York City.

This society will be a merger of the Welding Committee of the Emergency Fleet Corporation, and the National Welding Council, and will include others who may be interested.

It is the purpose of the society to become a disinterested and dependable source of information on welding, not only for the benefit of the manufacturers of welding apparatus and supplies, but also to aid those who use welding in their production and those who purchase goods into which the welding process enters.

The first meeting will be held Mar. 28, 1919, at the Engineering Societies' Building, 29 W. 39th St., New York, at 10:30 a. m.

Civil Service Examinations

For United States Civil Service examinations listed below, apply to United States Civil Service Commission, Washington, D. C., or to any local office of commission, for form 1312.

United States.—Superintendents of road construction, Bureau of Public Roads, Department of Agriculture, Mar. 25: Class A (candidates with four years' responsible charge of construction) $150 to $175 per month: Class B (six years' responsible charge) $185 t o$225; Class C (eight years' responsible charge) $230 to $250 a month. File applications before Mar. 25.

United States.—Assistant examiner, Patent Office, Washington, Mar. 26-28, and May 21-23 and July 23-25. Pay, $1500 per year. File applications in time to arrange for examination at place selected by applicant.

United States.—Chief physicist, qualified in aëronautics, National Advisory Committee for Aëronautics, Langley Field, Hampton, Va., Mar. 25, $3000 per year. Also physicist, $2100 per year. File applications before Mar. 25.

United States.—Senior highway bridge engineers, Apr. 1, Bureau of Public Roads, Department of Agricul-

ture, Washington, D. C. Grade 1 (examination percentage above 70) $2400 to $2700 per year; Grade 2 (percentage above 80) $2800 to $3000 per year; Grade 3 (percentage above 90) $3100 to $3400 per year. File application before Apr. 1.

Engineering Societies

Calendar

Annual Meetings

AMERICAN RAILWAY ENGINEERING ASSOCIATION; 910 Michigan Ave., Chicago; Mar. 18-20; Chicago.

NATIONAL FIRE PROTECTION ASSOCIATION; 87 Milk St., Boston, Mass.; May 6-8, Ottawa, Can.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

The National Highway Traffic Association will hold a public meeting at the headquarters of the Automobile Club of America, New York City, Mar. 21. The Hon. Francis M. Hugo, secretary of state, New York, will speak on "Qualifications for Operators of Motor Vehicles and Revocation of Licenses," and Shirley W. Wynne, Department of Health, New York City, on "Regulation of Pedestrian Traffic." Elmer Thompson, secretary of the Automobile Club of America, will read a paper on "Signposting for Detours and Through Routes in Municipalities." A committee report will be presented on "General Highway Traffic Regulations for Drivers, with Directions for Pedestrians."

The New York Chapter of the American Association of Engineers will hold a meeting at the Hotel McAlpin Mar. 28. C. E. Drayer, national secretary, will speak on "The Aims and Accomplishments of the American Association of Engineers." All engineers, whether members or not, are invited to attend and participate in the discussion. Mr. Drayer will spend two weeks in the East, studying the field in order to find how the association can best serve the profession in that part of the country.

The Engineers' Club of Columbus, Ohio, has made arrangements for permanent quarters in the Southern Hotel. Dudley T. Fisher addressed the club Feb. 28 on "Why Does the Inventor Fail to Receive the Expected Reward?" The legislation committee reported that Senate Bill No. 2 permitting chemical closets in school buildings had passed the Senate in spite of efforts against it by the club's committee and by the State Board of Health.

The Detroit Engineering Society held a meeting Mar. 7 at which David A. Molitor delivered an address on "The International Metric System of Weights and Measures." The society will hold a joint meeting with the Detroit Section of the Society of Automotive Engineers Mar. 21. Elmer A. Sperry will speak on "The Gyroscope in Modern Warfare."

The Colorado Association of Members of the American Society of Civil Engineers held a regular meeting Mar. 8, which was addressed by F. A. Banks, engineer, United States Reclamation Service, who spoke on "The Jackson Lake Dam, Wyoming." Mr. Banks' paper dealt with a description of development of storage and construction features and methods of delivering the stored water in the Snake River Valley, Idaho.

The Brooklyn Engineers' Club will be addressed Mar. 13 by James A. Donnelly on "Air Return Systems of Steam Circulation." Mr. Donnelly's paper will deal with steam and return mains and air-valve systems. On Mar. 20 Charles Evan Fowler will address the club on "Bridge Architecture and Construction," illustrated with lantern slides.

The Engineers' Club of Philadelphia was addressed Mar. 7 by Col. Edwin A. Havers, who spoke on "The Evolution of the Pen." I. W. Litchfield, director, technical division, United States Employment Service, will speak on "The Work of the Professional Section of the United States Employment Bureau," at the weekly luncheon Mar. 18.

The Michigan Engineering Society Feb. 28 appointed a special committee to consider the proposal for reorganization for the purpose of broadening the influence of the society by affiliating with it all the local engineering societies in the state, as mentioned in *Engineering News-Record* of Feb. 27, p. 448.

The Philadelphia Chapter of the American Association of Engineers recently elected the following officers: F. P. Roth, president; L. F. Boon, vice-president; M. F. Frick, recording secretary; H. F. Kuzel, David Lupton Son's Co., corresponding secretary.

The Montreal Branch of the Engineering Institute of Canada will be addressed Mar. 20 by W. H. C. Mussen on "Ball-Bearing Jacks" and by Ernest V. Moore on the subject of "Peat."

The Louisiana Engineering Society held a meeting Mar. 10 at which W. T. Hogg read a paper on "Suggested Changes in the Operation of the Street Railway System of New Orleans."

The Engineers' Club of Trenton will be addressed by William G. Thompson, state engineer of New Jersey, on "A National Highway Policy and Plan," at the meeting Mar. 13.

Personal Notes

MAJ. MARSHALL R. PUGH, Engineers, U. S. A., previously post engineer, Bordeaux Embarkation Camp, is now engaged in the cancellation of contracts for the United States Shipping Board, Emergency Fleet Corporation, having been discharged from Army service. Before the war he was in private practice as a member of the firm of Pugh & Hubbard, civil and sanitary engineers, of Philadelphia.

DR. HARLOW S. PERSON, director of the Amos Tuck School of Administration and Finance, Dartmouth College, and professor of organization and management, has resigned to become managing director of the Taylor Society, which will open permanent offices in the Engineering Societies' Building, 29 W. 39th St., New York City, Apr. 1. For several years Dr. Person has acted as president of the society, to which he will now devote his entire time.

MAJ. BRINTON BUCKWALTER, Ordnance Department, U. S. A., has been appointed manager of the New York branch, at 25 Pine St., of the Thompson & Lichtner Co., industrial and management engineers of Boston.

MAJ. WILLIS B. HAYES, Engineers, U. S. A., has been detached from the 210th Regiment at Camp A. A. Humphreys, Virginia, and has been appointed chief educational officer for occupational training at Base Hospital No. 31, Carlisle, Penn.

LIEUT. C. W. MARSHALL, Construction Division of the Air Service, U. S. A., previously assistant engineer, Bates & Rogers Construction Co. at Cleveland, has received his discharge and become sales engineer, Concrete Steel Co., western division, with office in Chicago. Lieutenant Marshall entered the service in 1917 and afterwards became assistant superintendent of construction at Ebberts Field, Arkansas, and Payne Field, Mississippi. He was later superintendent of construction at the flying field at Babylon, Long Island.

R. H. ROWLAND, previously associated with T. E. Murray, consulting engineer, New York, has engaged in private practice with office at 50 Broad St., New York City, as a designing and consulting engineer, specializing in mining, sugar and industrial plants.

J. C. MCVEA, office engineer, engineering department, City of Houston, Tex., has been appointed city engineer, succeeding E. E. Sands, who resigned

to engage in private practice, as noted elsewhere. Mr. McVea, who is president of the Houston Engineers' Club, is a graduate of the University of Texas and had been in the engineering department of the Southern Pacific Co. for about 10 years.

Arthur S. Hobby, previously associated with the Snare & Triest Co. at Havana, Cuba, has become assistant to the president, North Coast Rys. of Cuba, with headquarters at Moron, where he will have charge of construction work.

Lieut. Walter S. Anderson, of the Aviation Corps, formerly in the Chicago office of the Universal Portland Cement Co., attached to the inspection department, has been discharged from the Army and has entered the paving-plant department of the Lakewood Engineering Co., as field engineer, located in the Chicago office.

C. F. Horneffer, chief draftsman of the Austin Co., Cleveland, will be engineer in charge of design and construction of a destroyed glass plant at Maubeuge, France, which his company will build for Pilkington Brothers Co., St. Helens, England. Mr. Horneffer will organize his engineering staff and undertake the design entirely in England, employing English engineers.

R. H. Ford, engineer of track elevation, Chicago, Rock Island & Pacific Ry., Chicago, has been appointed principal assistant engineer with headquarters at the same point. The office of engineer of track elevation has been abolished.

Capt. H. K. Talbot, of the Construction Division of the Army, has resigned and accepted a place in the selling organization of the Koehring Machine Company.

John F. Greene, formerly construction engineer, Carter-Halls-Aldinger Co., Winnipeg, Man., has become associated with the firm of C. D. Howe & Co., consulting engineers of Winnipeg and Port Arthur, as manager of the Winnipeg office, in charge of bridge and structural work.

Capt. John H. Anderson, of the 212th Engineers, formerly of the technical staff of the Universal Portland Cement Co., has received his discharge from the Army and has become field engineer in the paving-plant department of the Lakewood Engineering Co., with office in Cleveland.

Charles A. Pohl has finished his work as head of the Concrete Shipyard Construction Section, Emergency Fleet Corporation, and has returned to general engineering practice in New York as a member of the firm of Bogart & Pohl, civil engineers. He will give his attention largely to hydraulic and steam electric powers, water-front developments and manufacturing plants.

L. C. Welch, chief engineer of the Midwest Refining Co., Casper, Wyo., has been appointed manager of the paraffine oil department of the company.

E. B. Ford, office engineer, Great Northern R.R., with headquarters at St. Paul, has been appointed assistant engineer, northwestern region, with headquarters at Seattle, succeeding T. G. Hastie, who has been appointed resident engineer, Great Northern R.R., with headquarters at Great Falls, Mont.

Capt. Frederick L. Jones, Construction Division, U. S. A., has been discharged from the service and has returned to his work in the firm of Jones & Hazel, engineer-appraisers, Watertown, N. Y.

T. G. Hastie, assistant engineer, northwestern region, United States Railroad Administration, with headquarters at Seattle, has been appointed resident engineer, Great Northern R.R., with headquarters at Great Falls, Mont.

Capt. John P. Wentworth, Sanitary Corps, U. S. A., has received his discharge from the service and has returned to his former position as assistant engineer with Metcalf & Eddy, consulting civil engineers, Boston.

Maj. E. L. Deacon, Air Service, U. S. A., formerly superintendent of construction, George A. Fuller Co., Detroit, has organized the E. L. Deacon Construction Co., with headquarters in Detroit.

Charles Carroll Brown, formerly of *Municipal Engineering*, has been appointed assistant maintenance engineer, Division of Highways, Illinois Department of Public Works and Buildings.

Capt. Edward Wright, Jr., Sanitary Corps, U. S. A., having received his discharge, has returned to his former position as assistant engineer, Massachusetts State Department of Health.

Lieut. Robert Goelet Carraway, U. S. A., recently returned from overseas, has received his discharge from the service and has resumed his work as managing engineer, Henry Exall Elrod Engineering Co., Dallas, Tex.

E. E. Sands, for the past five years city engineer of Houston, Tex., has resigned to enter private practice with headquarters in New York City, specializing in port and terminal development. He is a graduate of the University of Wisconsin, and for a number of years was connected with the United States Reclamation Service in the West, and with the Canadian Pacific Ry. Land Development Department.

Lieut. George A. McClellan, U. S. A., has been discharged from the service and has become associated with the Henry Exall Elrod Co., Dallas, Tex., as highway engineer for the northern and eastern portions of the state.

W. D. Shannon, inspector of hull fabrication, American International Shipbuilding Corporation, Hog Island, Penn., has resigned to return to his work with Stone & Webster in Boston.

Haven C. Kelly, divisional superintendent, track and roadway, Chicago City Ry., has been appointed superintendent of the department.

Obituary

Ralph H. Brown, vice-president and chief engineer of the Eastern Bridge & Structural Co., Worcester, Mass., died in that city Feb. 22. He was graduated from the Thayer School of Civil Engineering in 1885, previous to which he had served in the engineering department of the Painesville & Youngstown R.R. and in the office of the city engineer of Youngstown, Ohio. In 1885 he became associated with the Boston Bridge Works as assistant engineer, six years later becoming engineer in charge of the estimating department. From 1894 to about 1900 he was chief engineer of the company. He afterward became associated with the Eastern Bridge & Structural Co., of Worcester, and became vice-president and chief engineer.

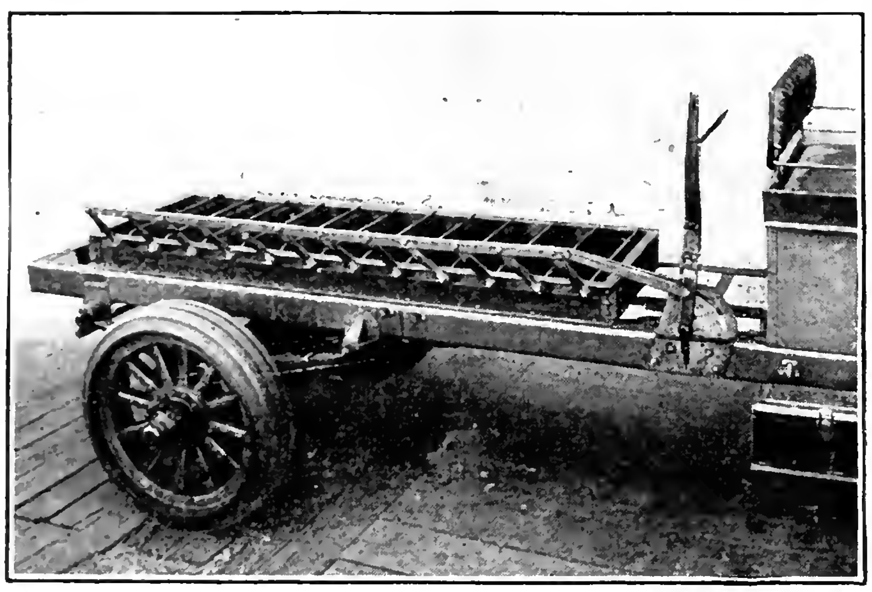
Frederick Hobart, for many years a member of the editorial staff of *Engineering and Mining Journal*, died in Flushing, N. Y., Mar. 9, in his 77th year. He had been in retirement since 1917. Immediately following his graduation from the College of the City of New York, he entered the Federal Army in the 9th New Jersey Cavalry, attaining the rank of captain. Returning to civil life, he became connected with the Jersey City Locomotive Works and was afterward assistant editor of the *Railroad Gazette*. He joined the staff of *Engineering and Mining Journal* as assistant editor in 1893.

George Welsby Scott, consulting engineer, Chicago, died Feb. 28 in Battle Creek, Mich. He had been engaged largely in appraisal work and at one time was associated with the Pullman Company.

Dump-Bottom Truck Body for Spreading Road Material

As a byproduct of his work as a highway engineer, W. L. Goodwin, 1515 N. 40th St., Seattle, has invented a device for spreading road material from a moving truck. It consists of a truck body bottom made of a steel frame with pivoted steel plate panels resembling in principle the old-fashioned wooden window shutter.

The bottom of the truck is made of steel channels forming a frame, which holds the cross-plates. There are 12 plates, each [illegible] in. wide, made of ¼-in. iron and with [illegible] x 1½-in. strengthening rod which acts as an axle. The picture shows how each of the panels is fastened by a crank handle to a longitudinal bar connecting all of them together. To the end of this bar is connected the lever which controls the dumping of the truck. This lever locks forward like a wagon brake, pulling all of the small steel panels into a horizontal position so that the bottom of the truck is closed to hold fine material. To dump the load in the truck this handle is released and, as the axis of each steel panel is off center, the weight of the load in the truck is heavier on one side of the axis than on the other, facilitating dumping. As the control lever may be locked at any one of several points, it is possible to leave the panels turned so that the material in the truck will work out gradually and evenly, according to Mr. Goodwin, and thus be distributed over a roadbed without hand labor.



DUMP BOTTOM FOR TRUCK INVENTED BY ENGINEER

The dumping bottom is designed for use with any motor truck or trailer where the machinery underneath the body will not be damaged by the falling material.

The device is now manufactured for local trade by the C. J. Young Iron Works Co., Seattle, Wash.

Hines To Address American Lumber Congress

A general lumber convention or congress, to which all branches of the industry are invited, on Apr. 14-16, will overlap the annual meeting of the National Lumber Manufacturers' Association on Apr. 16-17. Both will be held at the Congress Hotel in Chicago. Walker D. Hines, new director general of railroads, will address the Congress on Apr. 16.

Methods of retail service and the merchandising of lumber will be discussed Apr. 14, problems of manufacturers and distributors on Apr. 15, and questions of Governmental relations on Apr. 16, according to announcement. Lumber men hope that the congress will result in the formation of a national policy for the lumber industry.

Trade Publications

The Brandell Co., Union Central Tower, Cincinnati, Ohio, has issued a 6 x 9-in. 24-p. catalog which illustrates and describes "The All-Automatic Brandell Concrete Stone Machine."

Dimension drawings for the use of designers are included in a 95-p. book on the Jeffrey bucket conveyor, issued by Jeffrey Mfg. Co., Columbus, Ohio.

"Lighting from Concealed Sources" is the title of an 8 x 10-in. 245-p. cloth-bound book published by the engineering department of the National X-Ray Reflector Co., New York and Chicago. It is "a practical treatment of lighting problems to obtain satisfying illumination and individual effects without exposed light surfaces," and is profusely illustrated with half tones, line cuts, diagrams and tables.

"Insley Steel Guy and Stiffleg Derricks" is the title of Bulletin No. 110 of the Insley Mfg. Co., Indianapolis, Ind., illustrating and describing its products.

The J. D. Fate Co., of Plymouth, Ohio, has issued a series of bulletins covering industrial haulage by classes. The object of these bulletins is to show the application of the Plymouth gasoline locomotive to various industries.

The Joseph Dixon Crucible Co. has issued a pocket catalog listing lubricants and paints and pencils for mill, railroad and automobile use. The catalog also describes pencils.

The Brown Hoisting Machinery Co., Cleveland, Ohio, has issued Catalog K, 1919. It is an 8½ x 11-in. 93-p. paper-bound book illustrating, describing and giving diagrams and tabular data regarding the Brownhoist locomotive cranes.

The Blaw-Knox Co. announces its "products booklet," indicating the fields covered by its products.

"National Pavement—The Right Road" is the title of a 6 x 9-in., 20-p. pamphlet issued by the Permanent Highways Corporation, 50 E. 42nd St., New York City. It gives descriptions, illustrations and references regarding the work done by the corporation in various parts of the country.

The Novo Engine Co., of Lansing, Mich., has issued Bulletin No. 11 describing and illustrating hoisting outfits manufactured by the company.

Steel forms for concrete and monolithic brick pavements, for integral base and curb work, for curb and gutter building, and for beveled edges on concrete roads, are among the subjects included in a new booklet by the Blaw-Knox Co., of Pittsburgh.

Portable air compressor outfits is the subject of Bulletin No. 15 of the Novo Engine Co., Lansing, Mich.

Business Notes

The Moore Trench Machine Co., Rockaway, N. J., is about to resume operations with a full force of men, after a period of wartime idleness of about a year.

Export sales of railroad supplies to the West Indies and South America is the field of the M. C. Fairchild Co., with offices at 347 Madison Ave., New York. Mr. Fairchild has been with Fox Bros., New York, in the same field for a number of years.

A. S. Blagden, director, Air Reduction Co. has been elected president, succeeding W. W. Birge. A. R. Ludlow has been appointed vice-president; C. E. Adams treasurer, and M. W. Randall secretary. The Air Reduction Co. manufactures oxygen, hydrogen, nitrogen, acetylene, calcium carbide, and cutting and welding apparatus, under the trade name "Airco."

H. Y. Smith, formerly vice-president of the Kern-Hunter Co., Milwaukee, Wis., is now engaged under his own name in the handling of contractors' and industrial plant equipment, at 1227 First National Bank Bldg., Milwaukee.

The Clydesdale Brick & Stone Co., of Pittsburgh, Penn., announces that on Mar. 1 its office was moved from the Oliver Bldg. to 907-908 Hartje Bldg., Wood St. & First Ave., Pittsburgh.

Meeting the Cost of Water-Main Extensions

HOW best to meet the cost of extending water mains is not so easy a question to answer as may appear at first thought. Practice varies widely and does not seem to be based on comprehensive scientific study. The path of least resistance is the one most likely to be followed. Beyond attempts to avoid legal pitfalls, local feeling seems to control. The policy of the water board or city council may be liberal or the reverse, according to whether there prevails the idea of water service to all on easy terms, or strict regard for revenue in excess of capital and operating charges. Or the practice may range between these two extremes. The variations thus far considered relate to the division of responsibility for extensions between individuals and the city. Where the individual property owners must bear the whole or part of the responsibility there still remains the question: Shall they pay the first cost of the extension, or shall they guarantee a revenue for water which shall be a stated percentage of the first cost? If the property owners pay all or part of the first cost, how shall it be apportioned among them? The easiest way is to adopt the pro rata frontage basis. Is it the fairest and best way? If the property owners voluntarily and unanimously agree to such a plan, perhaps no one need complain, but if the city must use compulsion on some property owners then the question arises, Is the plan equitable? The subject bristles with questions.

Assessment of Benefits Deserves More Attention

INCREASED attention might well be given to assessments for benefits, as a means of meeting the cost of water-main extensions. This proposition was brought before the New England Water-Works Association at Boston last week. The discussion, briefly summarized on p. 591, was quite extended, but it ranged over the broader field of paying for water-main extensions discussed in the note preceding this one, and showed the diversity of practice already mentioned. The discussion indicated that the practice of making individuals assume responsibility for water-main extensions is common, and that often it is the property owner rather than the water consumer who must shoulder the burden. The examples cited did not show that an out-and-out benefit plan is commonly used, but, rather, that where the property owners are made responsible frontage is the basis of dividing first cost. More commonly, it appeared, there is a voluntary assumption of responsibility, whether on a first-cost or a revenue-guarantee basis. The discussion, common observation and any considerable knowledge of human nature, combine to show that such a plan leads to unfairness. Sooner or later, those who assume none of the responsibility get water without bearing their share of the burden. Taking all the foregoing facts and opinions into account, as well as the increasing difficulty in finding money for municipal improvements, the case seems to be strong for a thoroughgoing study designed to show for a considerable number of water-works, well distributed geographically, what the current practice is as to meeting the cost of water-main extensions, the details of the assessment-for-benefits plan whenever it is used, and the wisdom of extending that plan. The study should include consideration of how the benefits-assessment plan may best be adapted to water-works conditions.

Lessons From Spring Breakups

TIMES of excessive moisture are generally admitted to be the most critical periods in the life of road surfacings. This was abundantly proved by the experiences of last spring, when large sections of roadway which had successfully carried equal or greater traffic over dry subgrades were broken through as the frost left the ground. As excessive moisture is the recognized cause of these failures, the least that can be done at such times is to keep the ditches open so that the saturation of the subgrade will not be increased by standing water. A second precaution which might well be employed is to regulate heavy traffic at the critical time. If roads which will carry the loads for 360 days in the year are broken down by the traffic in the other five, as was the case in some instances last spring, it would seem the height of maladministration to allow the same thing to occur again. While in many sections there is little depth of frost this year, due to the clemency of the past winter, there is certain to be a season of excessive moisture, and every effort should be put forth by highway officials during the next two months to safeguard the public investment.

Highway Lettings Should Be Expedited

EVIDENCE of delay in the authorization of projects and the preparation of plans for country highway and city paving is making its annual appearance. Although March is nearly gone and plans should be ready for the spring opening, little work is being advertised for letting. Much of this delay is no doubt due to the hope among officials that there will be a decline in the prices of highway materials. This is a mistaken policy, both because investigations by economists indicate no immediate prospect of such a movement, and because the monetary value to the communities of immediate use

of good roads would largely counterbalance any possible saving in the cost of road materials. The disadvantage of a late start in highway work is apparent to all engineers. It means late fall work, under frost conditions, and possibly a shut-down for the winter months, thus delaying the completion of the contract and the utilization by the public of the money already invested. To these arguments against delay may be added the patriotic incentive to help out in the unemployment situation confronting the nation. The road-building season is short at the best, and highway engineers should urge their commissioners, councils and boards of public works to expedite the lettings.

Some Mayors Need Education

IN THE last minutes of the recent Governors' and mayors' conference in Washington the presiding officer read a resolution signed by a number of the 130-odd mayors present. It set forth that whereas a number of cities are interested in the purity of their water supplies, etc., etc., therefore be it resolved that Surgeon General Rupert Blue of the United States Public Health Service be requested to investigate the many systems of sewage purification—it may have read "sewerage" purification—and, as a result of this investigation, recommend the best system to use. This was the purport of the text; the exact words are not available, and it was not only signed, but advocated on the floor, by several of the distinguished heads of cities. This is not a joke, but a veritable occurrence. Engineers who are inclined to laugh at it should rather bestir themselves in their towns. Dissemination of the facts underlying great engineering operations or principles is apparently needed in many quarters.

No Military Control of Public Works

ALTHOUGH lost sight of in the confusion of the last days of the 65th Congress, the idea of a Federal Department of Public Works must not be allowed to die. Now is the accepted time for this most necessary change in the control of Government engineering operations, when Congress, through repeated appropriations, is alive to the extent of those operations, and, what is more important, to their divided control. Individuals must urge the Public Works Department idea; engineering societies must push it, but everyone should insist on a subordination of the military in this civilian department. Particularly will it be necessary to combat the idea that engineer officers of the Army must take charge of civil engineering works of the Government in order to provide them with the practical engineering experience necessary in war.

Granted that the Army's own work—barracks, fortifications, etc.—will not be sufficient to ground the Army engineer in the fundamentals of the construction and administration end of his profession, there is no reason why the engineer officer cannot be *assigned* to the civilian operations under the direction of a Department of Public Works, as has been done for many years in the British colonies. Let the Army engineer spend the proper amount of time in the Army organization—commanding men, studying and developing purely military engineering, building the structures and equipment necessary to the Army itself—and every so often let each officer be detached from his unit and assigned, as a civilian, with only a civilian's privileges and rights, to one of the multitude of engineering constructions that a proper Federal Department of Public Works would control. He could not thus carry over the asperity sometimes peculiar to the military uniform. That uniform would not bar the way of his subordinates to promotion. He would be, for the time being, a civil engineer in a civilian organization, learning many things of value to him in his profession of military engineer, and giving to the Government and to the job the benefit of his education and his experience.

A most powerful influence to bring about such a development will be found in the thousands of discharged soldiers. The Army, to these men, while a most necessary thing to have ready for war, demands a routine and a régime not at all fitted for the less rigorous operations of peace. They will insist, especially the engineers among them, that the Army stick to its military functions and leave Government civil construction to the less rigid and more democratic control of a peacetime civilian organization.

Plan to Eliminate Jurisdictional Strikes

EMPLOYERS and employed have taken an important step toward cementing the building trades into a league for the settlement of disputes as to union jurisdiction over work. The immediate purpose of the league, or board, as it is called, is to create a means for preventing strikes of building trades unions due to jurisdictional arguments.

Some months ago, at the separate but simultaneous instance of the American Institute of Architects and the Building Trades Department of the American Federation of Labor, the United States Department of Labor undertook to canvass the situation and suggest a working plan. After various conferences with labor leaders and representatives of the American Institute of Architects, a formal plan was drafted by John A. Lennon, and on Mar. 3 and 4, at Cleveland, Ohio, this plan was submitted for action to representatives of the building industry.

The plan submitted called for the creation of a body to be known as the National Board of Jurisdictional Awards of the Building Industry, to consist of eight members and eight alternates, four to be selected by the Building Trades of the National Federation of Labor and one each by the American Institute of Architects, the American Society of Civil Engineers, the Associated General Contractors of America and the National Association of Builders' Exchanges. The duties of the board are to hear and determine claims for jurisdiction over work performed, and make award in conformity with the facts. A three-fourths majority vote of the full board is required to fix the award, and it is provided that all local arbitration committees shall insert in the agreement between employers and employees a clause as follows: "The decisions of the National Board of Jurisdictional Awards of the Building Industry shall be final and binding upon the parties to this agreement."

Engineers, contractors and union labor have thus demonstrated their capacity for coöperative action for mutual benefit. This is an attainment which looks far beyond the immediate object sought. It promises, ultimately, a real partnership of management and labor in the construction industry.

Will Prices Fall?

WILL PRICES FALL, is the national question of the day. Upon its answer depends to a large extent the business activity of the near future, and upon that business activity in turn depend social questions of tremendous import. From time to time *Engineering News-Record* has commented upon the situation, the sum total of that comment being that prices are not likely to fall to any material extent in the near future. This conclusion has been predicated upon the belief that the total of the peace-time demand will not be far short of the war demand itself. During the war there was produced a tremendous shortage in practically every kind of commodity. There is an oversupply here and there, but the instances are isolated and entirely out of harmony with the general situation. That shortage must inevitably be overcome unless the peoples of this world lower materially their standards of living. History and the disposition of the public in every country of the globe give us the assurance that living standards will not be lowered. In fact, they are quite likely to be raised, still further increasing the post-war demand and assuring that it will be not much below that of the maximum war demand itself.

Reinforcing this point of view is the testimony of the periods following the Napoleonic and Civil Wars, graphed and discussed by Morris Knowles in *Engineering News-Record* of Feb. 27, 1919, p. 414.

Now Irving Fisher, professor of political economy in Yale University, approaching the problem from an entirely different standpoint, draws the same conclusion.

He takes the position that the world has advanced to a new price level, and that this new price level is no more likely to be receded from than were the price levels brought about by the great influx of gold and silver into Europe from the mines of the new world in the sixteenth century, or that caused between 1896 and 1914 by the discovery of the gold fields of South Africa, Cripple Creek and Alaska, the invention of the cyanide process in mining, and the vast extension in the use of bank credits. In other words, he sees in the present price advance, even though brought about by the urgency of war, a permanent change in the plane on which the world must do business.

Explaining his position, Professor Fisher adverts to the well known and thoroughly established fact that the general level of prices is dependent upon the volume and rapidity of turnover of the circulating medium in relation to the business to be transacted thereby. As he puts it, "If the number of dollars circulated by cash and by check double, while the number of goods and services exchanged thereby remains constant, prices will about double. Over $1,000,000,000 in gold has come into this country from abroad since 1914, and a large amount has disappeared from domestic circulation. On June 30, 1918, the portion of the gold reserve of the Federal Reserve banking system which supported national bank deposits and Federal Reserve notes was more than three times as large as the gold reserve under the old national banking system on June 30, 1914—$1,786,000,000, as compared with $592,000,000. During the same period, credit instruments (demand deposits and notes) increased about twofold—from $6,100,000,000 to $11,700,000,000. It is this increase of credit instruments, typical of the banking situation for the country as a whole, which, Professor Fisher points out, largely explains the present high level of prices.

Moreover, we are not at the end of the possible limit of expansion even now, provided we take the same view of our financial structure, or at least of the ratio between credit and gold, as we did in the pre-war period. At the present time the ratio of gold to credit has risen from 9.6% to 15.3%, while the reserve requirements of the present system are such that for 1918 there was an excess of gold above legal requirements of more than $700,000,000. The reserve required by law to support the $11,700,000,000 of credit instruments of 1918 is $1,070,000,000. The $700,000,000 of free gold could support an additional superstructure 70% as large as the existing one, which indicates that for the banking of the country as a whole a potential future expansion of 50% is a conservative estimate.

Discussing the situation from the standpoint of so-called "inflation," Professor Fisher points out that by inflation we mean merely the use of more circulating medium than is needed to transact the business of the country on a given price level. Whether or not we have inflation, therefore, depends upon the price level. If the price level of 1913-14 be considered normal, there would certainly be inflation now, but our currency is not inflated at the present time relative to the new level of prices in the world which the war has brought about. In other words, any expectation that there will shortly be a disappearance of this so-called "inflation" is based on the assumption that normal prices are those of 1914.

Looking to the future, there is no hope in sight for credit contraction; another large Government bond flotation is at hand, with the possibility of still another. After that there should be some contraction in the volume of credit, but Liberty and Victory bonds then in the hands of the people will be unrivaled bases of credit, and, experience shows, will undoubtedly be used for that purpose, thus tending to keep up the outstanding credit volume. He does not contend that it is absolutely impossible to bring down the price level, but argues that the experience of history and the possibilities now open for world-wide expansion point to the maintenance of present prices permanently or at least for a long period of years. Between the period of temporary and of permanent effects there may be a slight dip in the price level, say a year from now, but the possibility of that, he holds, is all the more reason why business should proceed now and not wait a year for the dip.

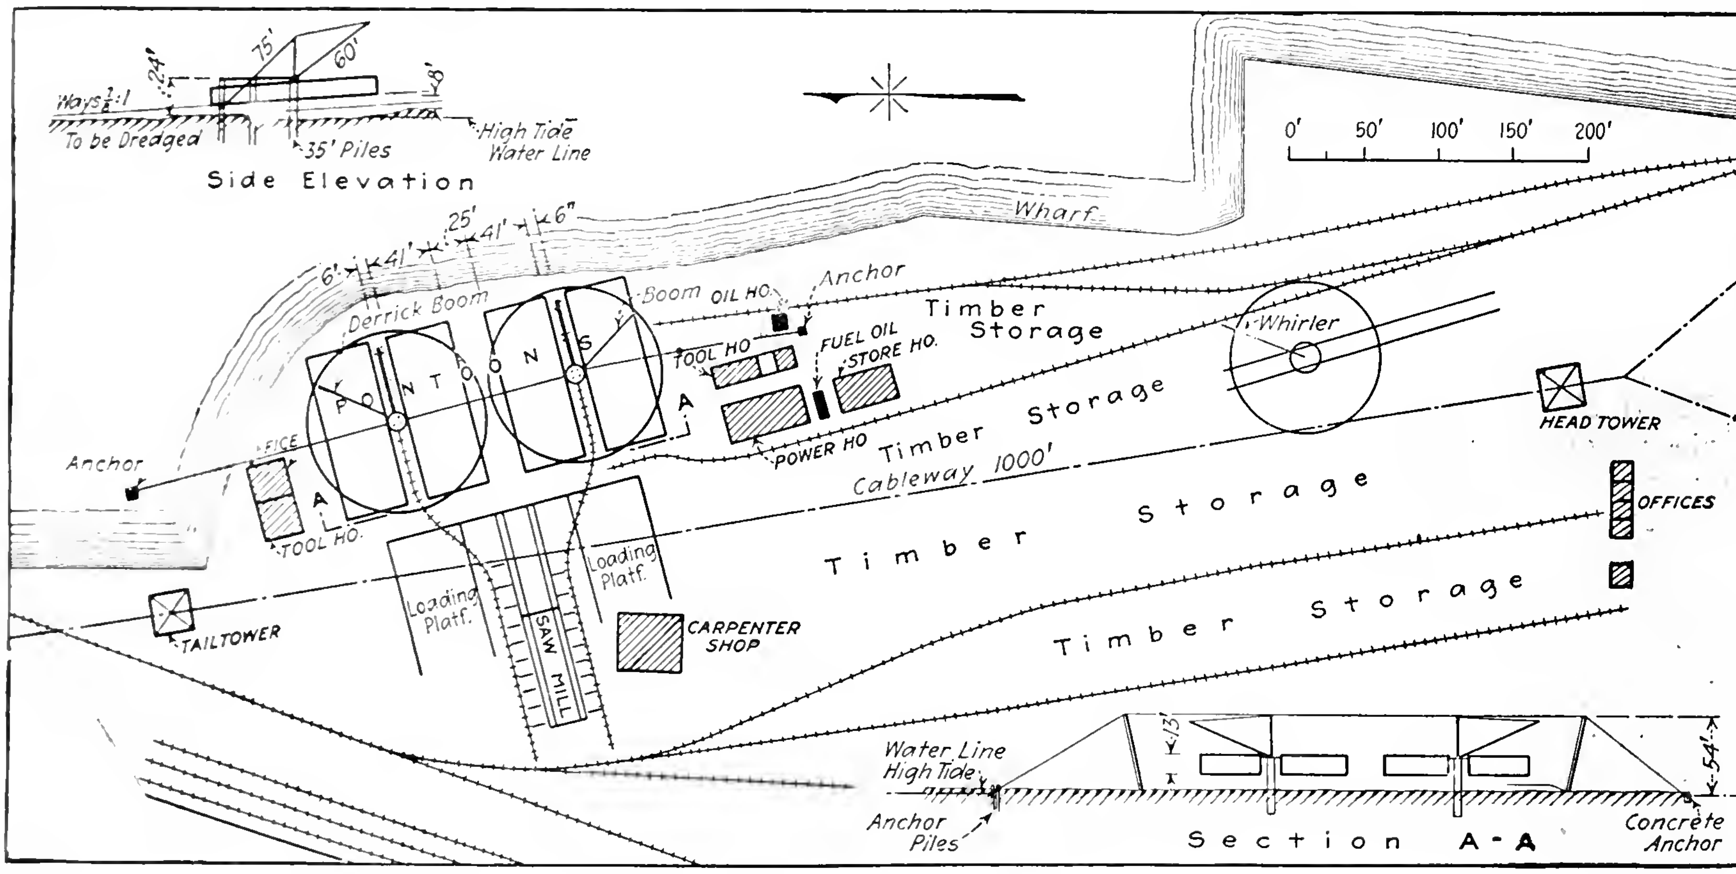
The conclusion to be drawn from this situation is that the sooner the business men of the country take the view that we are on a permanently higher price level and adjust themselves to it, the sooner will we save ourselves and the nation from the misfortunes that will come if we persist in our present false hope of expecting prices to come down, meanwhile creating a dangerous unemployment situation. Since the armistice, the buyers of the country have made an unexampled attack upon prices through their waiting attitude, and yet price recessions have been insignificant.

The clever man, Professor Fisher concludes, "is not the man who waits, but the one who finds out the new price facts and acts accordingly." What applies to the business man applies to Government officials, local, state and national, who hold a greater responsibility just now than the individual business man, for in their keeping rests national stability. If they will proceed with public works, the mills and the mines will operate, the whole industrial fabric will be strengthened, and the ominous prospects of business depression will disappear.

Building a Floating Dry Dock in Well Laid Out Yard

Cableway Assisted by Whirler and Derrick Car Keeps Heavy Timbers Ready for Carpenter Crews—Large Band Saws and Cutoffs Frame 12 x 12's Handled on Two-Way Roller System

MATERIAL for the 10,000-ton floating dry dock now under construction at Galveston, Tex., for the Galveston Dry Dock and Construction Co., moves through the yard with order and precision. To this fact and to the layout of the yard which permits this ready hauling of material, is attributed much of the speed and efficiency with which the work is being forming the heart of the material-transportation system on the job. At one end of the yard a whirler derrick on a 12-ft. track was set up between the cableway and the railway siding, and is used to unload material directly to skids under the cableway. The sawmill was placed at the other end of the lot between the other track and the cableway at a point opposite the four



LAYOUT OF YARD WHERE FLOATING DRY DOCK IS BEING BUILT AT GALVESTON

carried out. The dry dock consists of 11 wooden pontoons each 41 x 110 ft. in plan and 13 ft. high which are built on four parallel ways and launched endwise, to be tied together afterward by the plate-covered steel frames which form the dry-dock wings.

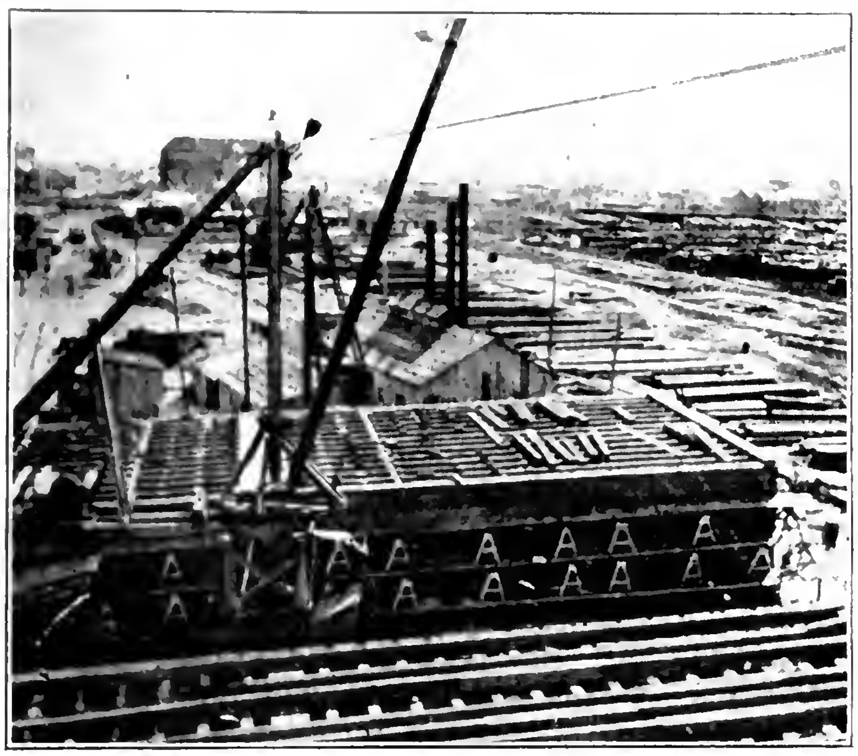
The ground selected for the construction of the pontoons, as shown in the drawing, afforded two railroad connections and a wharf. A cableway was laid out along the length of the lot between the railway tracks, ways. A derrick car unloaded onto the storage skids and platforms near the mill that part of the material which required framing. Other material was unloaded at the other end of the yard directly under the cableway. The storage piles were so laid out that the longest timbers required could pass between them while going from the mill to the derricks on the standard-gage four-wheel cars of the feeder tracks. Each track fed one derrick. As the tracks passed under the cable-

PANORAMA FROM CABLEWAY TOWER AT END OF YARD USED FOR BUILDING PONTOON UNITS FOR A FLOATING DRY DOCK FOR GALVESTON, DRY DOCK AND CONSTRUCTION COMPANY

way the cars also received material for the derricks from the cableway.

The mill itself is composed of two units, although under one roof, run by one engine and fed by a derrick car and cableway. Each unit consisted of a 36-in. band saw and a cutoff, one 36 and the other 42 in., and a roller conveying system from the storage piles. One joiner and one rip-saw served both sides, and one engine drove the two lines of shafting which took care of all equipment. Each side of the mill supplied the derrick nearest it.

Large saws were used, as the timber to be cut was all of large dimensions. The swinging cutoffs were found very useful in squaring ends and cutting lengths, while the band-saws were used for bevel work where the weight of the piece to be cut would permit maneuvering at all readily. Extremely heavy pieces were cut with a pit-saw by hand. A box templet was used to

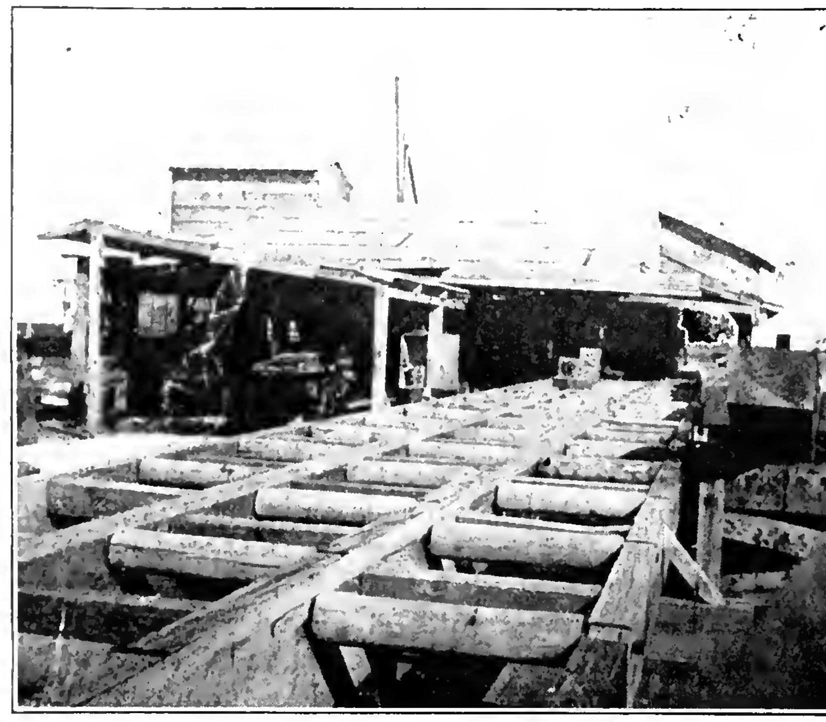


THIS DERRICK WAS ABLE TO BUILD TWO PONTOONS SIMULTANEOUSLY, EACH 41 x 110 FEET

get a true cut, and the timber was placed on a platform to eliminate the necessity of a pit.

The platforms adjoining the mill were built of timbers bought for the pontoons and used in them at the end of the work. As pieces requiring but little framing were selected, there was little mill work left to be done after the platforms were torn up. The ground blocks and the struts which sat on them were the only timbers bought for the platforms.

To facilitate easy handling, the tops of the mill platforms, skids and rollerways were made level with the tops of the saw tables. Rollerways on both sides, running close to the cutoff, led from the end of the platform by the switch to the end of the pontoon ways. On the switch side two more rollerways were placed beside the one toward the center of the mill. Outside were 8-ft. horses built with cast-iron rollers projecting from their tops, for the purpose of conveying timbers in a direction across the length of the piece. These rollers overlapped each other in plan, so that an 8-in. piece would always be on two of them and not edge between the rollers and the stick. The idea of these rollers was obtained from work of the Midland Bridge Co. in Houston.

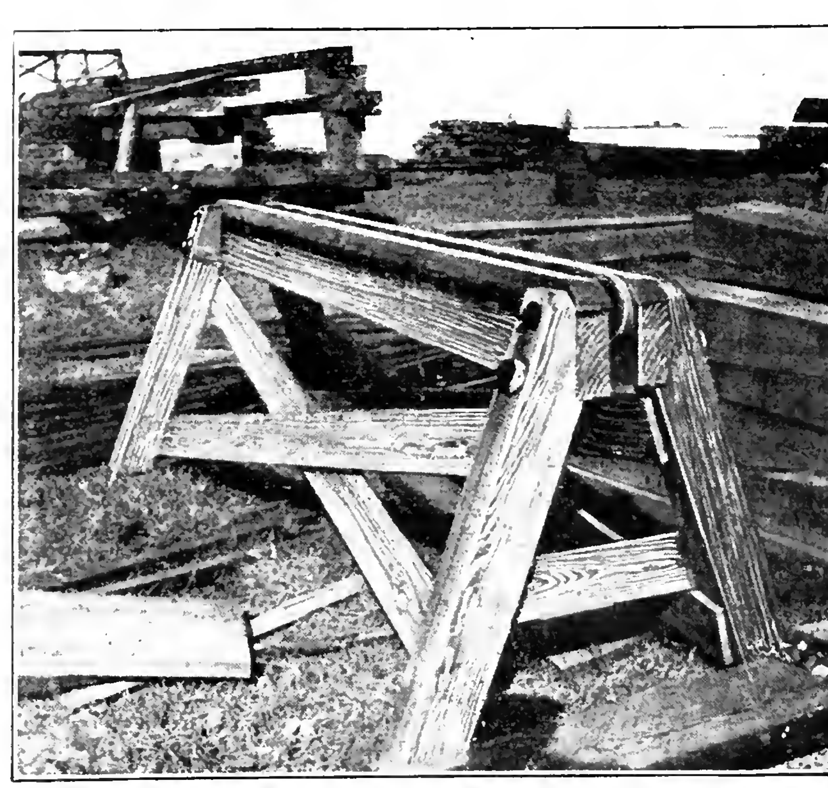


ROLLERS THAT HANDLE HEAVY TIMBER AT SAWMILL

Timber was stored in a long pile under the cableway and in several piles around the mill. The cableway pile held the material for six pontoons when piled to a height of nine feet.

The skids away from the mill were only built high enough to keep the timber off the ground and to allow a chain to be passed readily underneath.

Another point that made for smooth, quick work was the fact that the derricks at the ways were raised high above the pontoons. The engine runners could see directly and at close hand the placing of almost every piece they handled. Free motion of the boom is afforded by this elevation, as well as by the use of a single stiffleg and an overhead guy. One cable runs over the top of the two derricks and on over two masts, one at each end, placed clear outside of the area occupied by the pontoons. The ends of this cable are anchored after passing these outside masts. The stiffleg on each derrick secures the mast in two directions, and the guy

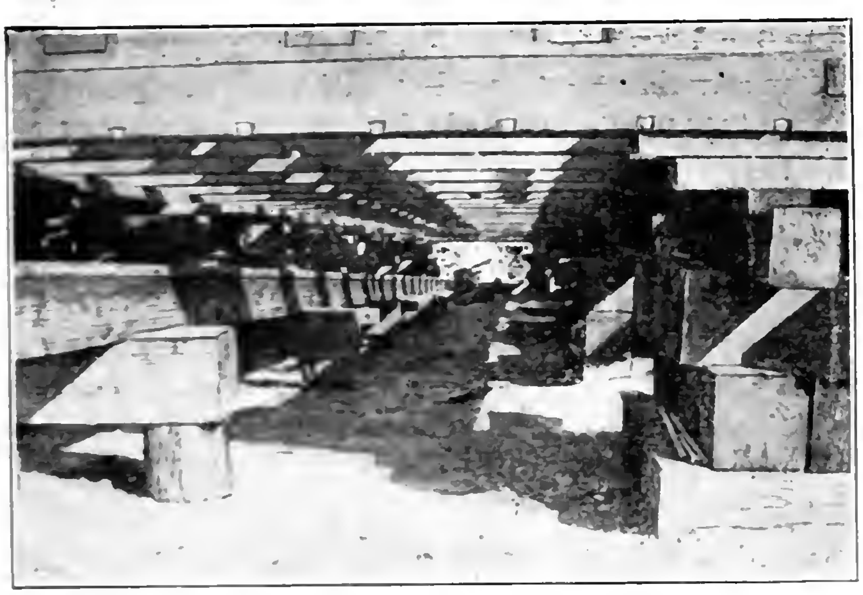


A HEAVY TIMBER LAID ON SEVERAL OF THESE ROLLER HORSES PLACED SIDE BY SIDE IS EASILY MOVED

over the top holds it in the two opposite directions, thus securing the derrick.

Support of the pontoons during construction was provided at the ways by piles of blocking topped by 8 x 12-in. wedges, as shown in one view. The flooring on the bottom of the pontoon was then placed, and the sliding ways were set and blocked against the bottom of the finished pontoon. The fixed ways were built of 9 x 9-in. timbers bolted together to form a 9 x 18-in. piece with staggered joints. This was laid flat on the supporting pile caps. With the blocking snugly set between the ways and the pontoon, the weight of the latter was delivered to the former by loosening the wedges on top of the blocking upon which the pontoons had been built. In one or two cases it was necessary to dig under these blocks and allow them to settle, but usually the wedges themselves moved readily enough. The upper or sliding ways were flanged instead of the lower or fixed ones, which required less flange material, as the upper ways were the shorter.

After it was launched, but before it was towed to the assembly slip, each pontoon was loaded with steel for the wings. These wings are water-tight steel walls which are continuous over the several pontoons, and so assemble them into a unit, the finished dry dock. A joint is made in the wings, however, so that the 10,000-ton dock may be divided into two units, using four and seven pontoons, respectively. The framework of the wings is erected by a derrick barge which also handled the outside plates. The inside plates are raised by a hoisting engine using a line through a block fastened to the top of the framework. A permanent compressor plant was outfitted early so as to supply air for driving the 300,000 rivets used in the wings.



DETAIL OF BLOCKING AND WAYS

In order to hold the pontoons firmly in the correct position during the placing of the wings, four wooden trusses are bolted to the pontoons, holding the two pontoons being attached to those already assembled. When new pontoons are to be attached the trusses are moved ahead.

The construction and assembly of the dry dock are being done by a Missouri Valley Bridge and Iron Co. organization headed by F. E. Washburn as engineer in charge. C. W. Cubbage is superintendent on the work in the pontoon-building yard, and F. L. Brock is superintendent of steel erection. H. A. Treat is general manager of the Galveston Dry Dock and Construction Co. The dry-dock design, including assembly trusses, was made by William T. Donnelly, of New York.

Army Trade Skill Tests Applicable in Construction

Half an Hour Tells Whether Workman is Expert, or Merely Skilled, or Is a Novice—Clerks Can Conduct Tests

BY SIMPLE oral, picture and performance tests any contractor or works manager can determine whether a workman seeking employment is an expert, or is merely skilled, or is only a novice in his trade. This is the conclusion which may be drawn from the experience obtained in classifying the men of our new National Army, stated Col. Walter Dill Scott in an address before the Chicago Chamber of Commerce, Feb. 12, 1919.

Half of the men in a modern army must be skilled at special trades in order to perform their duties. The new Army had, of course, to avail itself of the trade knowledge and experience which recruits brought with them from civil life, since time was not available for training men in trade skill. To discover this talent and assign it where needed was the task of the Army personnel organization, in which Colonel Scott served.

Until Nov. 11, 1918, when the armistice went into effect, 250,000 men who had professed trade skill had received special trade tests. There had at that time been standardized 71 oral, 12 picture and 19 performance trade tests, and 42 additional picture tests and six additional performance tests were in preparation. Some of these main tests were subdivided, so that in reality the count was greater than the figures given indicate. For example, there was a test for carpenters and an extension of this test for ship carpenters. A single test, or any two tests, or all three tests were employed, depending upon the man or upon the trade.

Oral tests consisted of a series of weighted questions. If the applicant's answers counted less than 15 points he was graded among the novices; if they counted from 16 to 31 points he was graded among the apprentices; if they counted from 32 to 55 points he was graded as a journeyman; and if they counted over 55 points he was graded among the experts. Every question was written and had to be put as written; it could be repeated, but its wording could not be changed in the repetition. Thus the test could be conducted by any intelligent clerk, after a little training.

Performance tests were equally simple. If a carpenter, for example, the man received a rough-sawed 2 x 4 in. timber, say 2 ft. long, to fashion according to a blueprint plan. This print called for one end to be beveled, a dove-tail mortise to be cut in the opposite end, all four sides to be dressed, etc., all to the exact dimensions shown. All the tools necessary for the work were provided, and a time was set for completing the job. At the end of the period set, the work was examined, and by its approach toward completion and its quality and exactness the man was rated as an expert, a journeyman or an apprentice in skill, or merely as a novice. In the same way a blacksmith was required to make to blueprint a simple eyehook, using two pieces of metal so that his skill in welding would appear. As in the case of the carpenter, all needed tools were provided and a time limit was set.

Picture tests were intended to show the man's knowledge of the tools of his trade. If he were a horseshoer a large card on which were pictured ten or a dozen numbered tools and articles commonly used in horse-shoeing was shown him. He was asked to name No. 1, No. 2, and so on and was marked on the accuracy and precision of his designation of the tools and articles. Precision of definition was held important. For example, if picture No. 5 showed clinch tongs, it was reasoned that anyone could answer "tongs," but only a man who knew about horseshoeing would answer "clinch tongs."

An average of about 30 min. per man was required to make the tests. To determine how and where to place the men, job analyses were made. These gave for each department of the Army the number and kind of skilled men needed, and designated the degree of expertness required for each position. The task of fitting the man to the position was then comparatively certain.

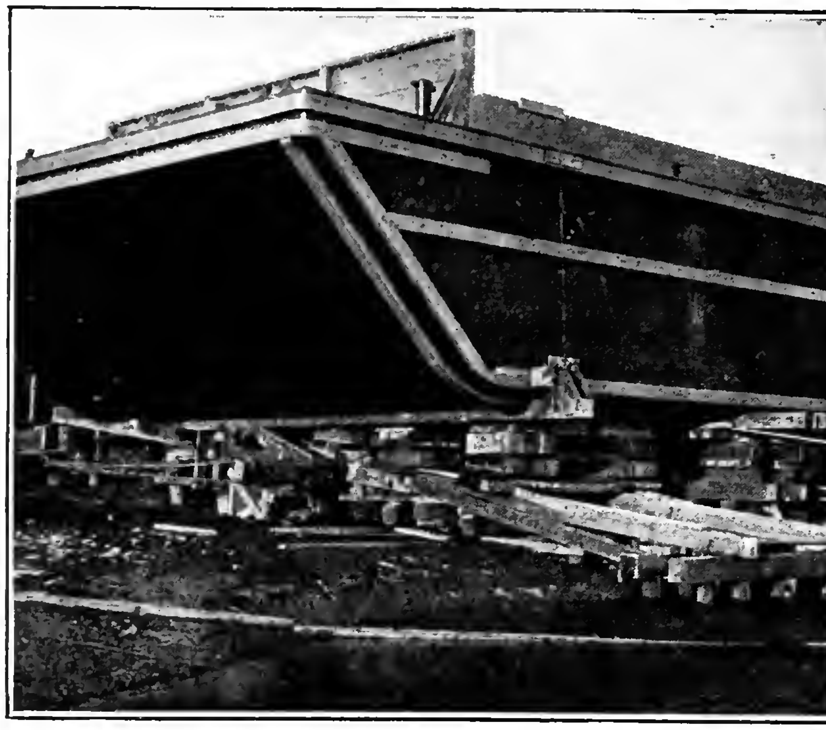
Trade tests only have been mentioned; as a matter of fact, classification by similar methods was made of 3,365,000 enlisted men and 194,000 commissioned officers. When the war stopped, stated Colonel Scott, "the work was well under way, and in another year we should have had a real army in which we would have known the capacities of the men and the positions in which men of these capacities were needed. The process is equally applicable to any kind of business."

Side Launching a Concrete Lighter

After Concreting, Boat Is Lowered to Four Sliding Ways by Jacks and Is Launched by Releasing End Cables

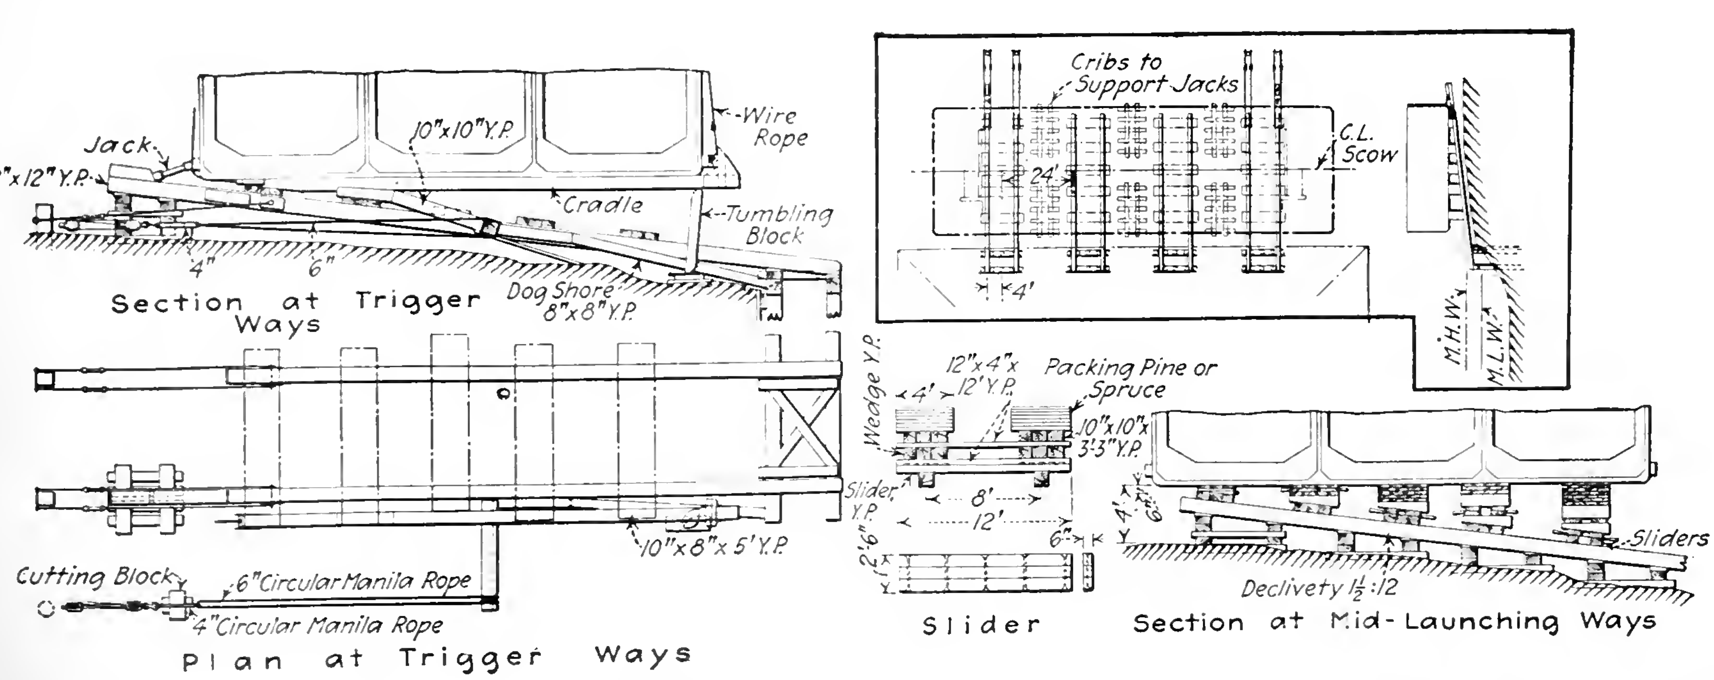
CONCRETE lighters 112 ft. long, $11\frac{1}{2}$ ft. deep and of 34-ft. beam, weighing about 500 tons, have been launched sideways at the yard of the Aberthaw Construction Co., at Providence, R. I. The construction of the lighters was described in *Engineering News-Record* of Oct. 7, 1918, p. 704.

Four pairs of launching ways were placed under each lighter, the ways being built at mean high-water level, with the outer ends just awash at high tide, and the area immediately in front of the ways, 100 x 130 ft., was dredged out to a depth of 4 ft. The ways are set at an incline of $1\frac{1}{2}$ in. in 12 in. and are built of 12 x 12-in. yellow pine, dressed smooth on the top and resting on sills laid in trenches, the outer end being supported on piling. Each pair of ways is 9 ft. wide, outside measurement, and the pairs are set at an interval of 24 ft. between centers. Across each pair of ways, under each longitudinal bulkhead and in the center of each water-tight compartment, was placed a yellow-pine slider which carried the wedges and blocking.



ONE END OF CONCRETE BARGE ABOUT TO BE LAUNCHED, SHOWING CRADLE AND TRIGGER

The outer unit of each pair of ways at either end of the lighter constituted the trigger way, being extended to the rear and capped with a piece of yellow pine to afford a bearing surface for the base of jacks which served to start the vessel on the ways. The trigger ways were reinforced by two 1-in. round steel



DETAILS OF LAUNCHING AND TRIGGER WAYS FOR SIDE LAUNCHING OF THE ABERTHAW CONCRETE BARGES

bars fitted with turnbuckles and running back to deadmen which also served to anchor the block and tackle which formed part of the releasing gear.

Under the lighter at either end was placed a cradle of 10 x 10-in. yellow pine fitted with an eye at one end and at the other a lip which set against the side of the barge, the shoe being held snugly against the bottom of the lighter by a ½-in. wire rope running up to the deck. On the under side of the shoe is a recess to take a strut running down to the trigger bar, which was a piece of 10 x 10-in. oak; the outer end of this was fastened to a deadman by a manila rope 6 in. in circumference, doubled and made taut by means of a block and tackle attached to the deadman in the rear of the launching way. The block is connected to the 6-in. cable by a double strand of 4-in. manila rope passing over the cutting block. From the outer side of the trigger a dog shore, 8 x 8 in., butted against the piling on the outer end of the launching way. Directly under the side of the barge was placed a tumbling block, beveled at either end; this fell clear when the lighter started down the ways.

When the concreting had been completed the barge was jacked up on building movers' jacks, carried on railroad ties on either side of each launching way, and the formwork was removed. The barge then was lowered to the blocking on the sliding ways. From this point, the barge was kept in place on the ways by the cradle shown, the strain being taken by the manila cables attached to the trigger bars.

A few turns on the jacks served to loosen the ship on the sliding ways, and, the signal being given, the releasing gear was severed simultaneously at the two cutting blocks. The resistance of the vessel striking the water broadside was sufficient to arrest the momentum, no rope stops being necessary.

Chloramine Tried by New York City

THE application of the chloramine process to the somewhat polluted water of Esopus Creek before it goes into the Ashokan reservoir at the head of the Catskill Aqueduct was described at the February meeting of the New York Section of the American Water-Works Association by Dr. Frank E. Hale, director of laboratories of the Department of Water Supply, New York City.

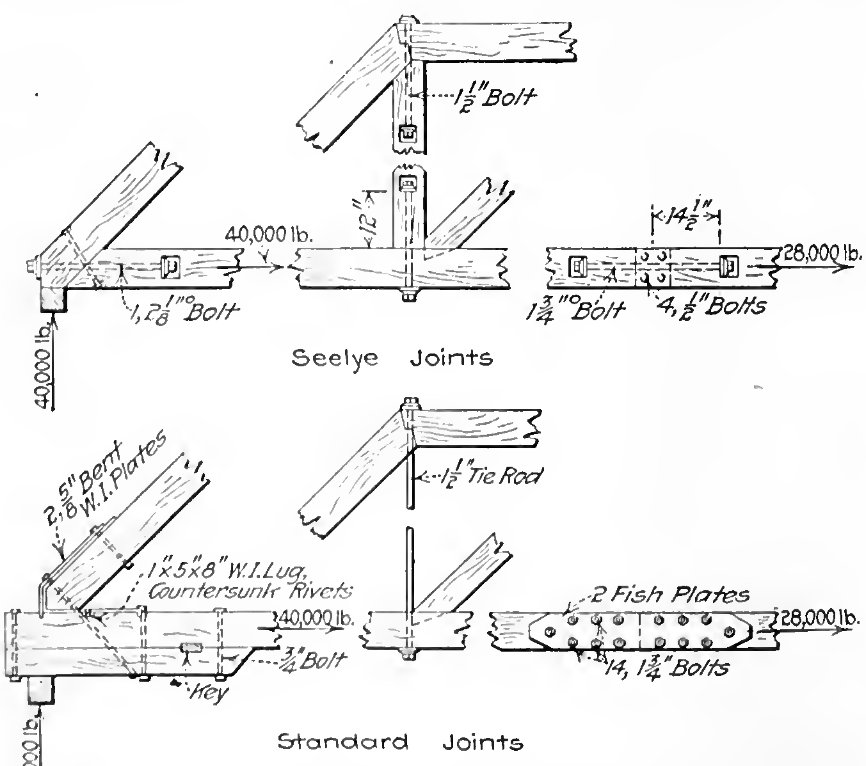
Although the water from the Ashokan reservoir has a long period of storage and is subjected to treatment with liquid chlorine before it reaches New York City, chlorination of the water of Esopus Creek before it reaches the reservoir was considered desirable. This was decided on in 1917 as soon as control of the Catskill watershed was taken over by the department. Local conditions prevailing at that time led to the adoption of hypochlorite instead of liquid chlorine for the Esopus Creek water. Immediately upon introduction of the hypochlorite (0.4 ppm.) complaints were received that the water was killing trout in the creek. This led to trial of the chloramine process (ammonia used with the hypochlorite), in an attempt to reduce the amount of chlorine and sludge. A material reduction in the unit rate of free chlorine applied (from 0.4 to 0.1 ppm.) was found to be possible, with good bacterial results and elimination of the fish problem, but the comparison of results obtained throughout more than a year's study indicated that equally good results were obtained by the use of hypochlorite alone. For example, the total bacteria and the B. coli removal with application of 0.05 ppm. available chlorine, bleach compared with chloramine, was, respectively, for bacteria 71% and 74%, and for B. coli 98% and 96%. These results indicated that the cost per unit of available chlorine applied for chloramine was double that of hypochlorite alone, since the ammonia cost four times as much as the hypochlorite, and the relative amounts of each applied were in the inverse ratio of one to four. This ratio was indicated by the experiments to be the correct ratio, the formation of chloramine being shown by a decidedly larger amount of free chlorine in the treated water than when bleach alone was used.

An important point brought out in the paper was that a given amount of available chlorine applied, and found by analysis to be actually in the water, did the same work—that is, percentage removal of bacteria and of B. coli—*at all temperatures,* winter or summer, from 32° F. to 76° F. Another point to be emphasized is that very small amounts of available chlorine may be effective in waters of low mineral and organic content.

The paper and discussion following brought out the fact that chloramine cannot safely be used except where there is very strict laboratory control, since otherwise the hypochlorite and the ammonia are likely to result in a variety of reactions and compounds, depending chiefly upon the proportion of chemicals applied and the strength of the solutions.

New Tension Joint for Wood Truss

BY APPLYING a type of tension joint common to certain kinds of cabinet work to wood trusses, Elwyn E. Seelye, consulting engineer, New York City, has made possible the framing of a truss in wood without the use of special plates, beveled washers, long



UPPER DETAIL SHOWS SEELYE WOOD-TRUSS JOINT AND LOWER SHOWS TYPICAL FRAMED JOINT

bolts, keys or complicated mortices. The joint, shown in the upper part of the cut, consists of a central bolt seated against the sides of through holes in the truss members. Comparison with the usual type of truss framing is made in the two drawings.

Fabricated Ship Construction at Bristol Yard

Plant and Operating System Closer to Precedent Than Those of Other Agency Yards—Reinforced-Concrete Shipways Flush with Ground—Tower Jib Cranes Traveling On Trestles—Pre-Assembly Practice

FABRICATED-SHIP construction at the Bristol yard of the Merchant Shipbuilding Corporation involves fabricating about 17% of the hull material in the yard shop. The working system, therefore, differs radically from that of Hog Island and Newark Bay, the two other original agency yards of the Emergency Fleet Corporation. Of these two, the former was planned for 100% and the latter for about 95% bridge-shop fabrication, as compared with the 83% of Bristol. In the planning of the Merchant yard this condition exerted a controlling influence, and led to close co-ordination of shop and berths. In this as well as in most other points of layout, shipyard precedent was largely adhered to. Furthermore, the derricks which at the other fabricating yards recall the bridge erector are not found at Bristol; in their place, traveling tower derricks are provided for the ship-erection service.

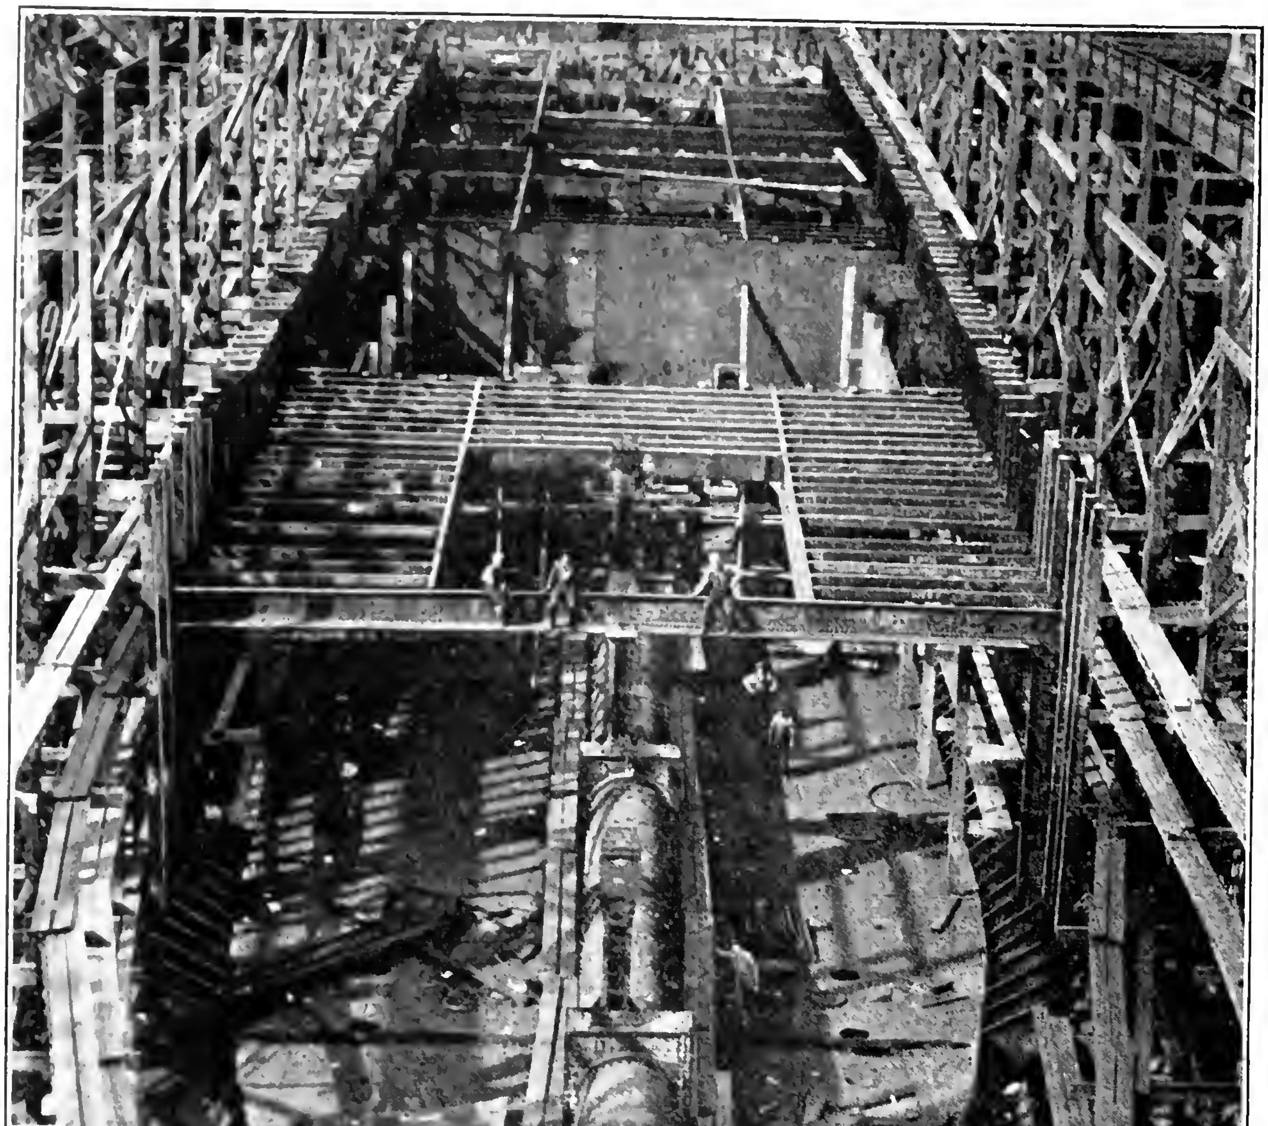


FIG. 1. MATERIAL FROM WAY-HEAD TRACK IS PLACED BY TOWER CRANES—PARALLEL MIDDLE BODY MAKES FABRICATION EASY

Included in the work fabricated in the shipyard punch shop are the following main items: All furnaced plates (in ends of shell as well as in keel and at knuckle), all bent frames, bottom angles on floor frames in forward and after sections, margin angles and web frames outside of the parallel body, frames and floors in peak, deck stringer angles at ends, ventilators and miscellaneous material. The work involved is estimated to cover about 40% of the total fabrication work required for the ship. The division was based on the desire to allot to the bridge shops only that work which they could do most economically with their existing equipment. Accordingly, of the bridge-shop material about 90% is either multiple-punched or rack-punched, and only about 10% single-punched.

To facilitate the outside fabrication as much as possible, the Merchant designers developed a transverse section of the 9000-ton ship which was to be built showing typical transverse rivet spacing, from which the shop men could set up their multiple punches direct. Pole templets for the longitudinal spacing of the multiple-punch rack could also be made from a drawing direct. The Merchant shop made templets only for the ends of the ship where the plates could not be multiple-punched; for this work it furnished the bridge company with one set of templets, which were then copied at the bridge shop to provide templets for the various plants at which the steel was to be fabricated. Rolled plates for the molded ends of the ship are punched at the bridge shop but are not rolled, so that they can be shipped flat; the rolling is done in the yard shop. Convenience in shipping also dictated the limit to which pre-assembly of parts at the bridge shops was carried. It is stated by officials that except for shipping reasons it would be possible to do approximately twice as much riveting in the bridge shop. According to the contract division of the work, the bridge shops drive about 100,000 rivets out of a total of 625,000 in the hull.

The general scheme indicated by the preceding was worked out for executing an order of the Emergency Fleet Corporation to build 40 steel cargo ships of about 9000 tons dead-weight carrying capacity. This order was subsequently increased to 60 ships of the same size. The contract time for completion of the order is about two years from September, 1917, when the contract was executed. Twelve shipways were laid out to carry this program through.

Character of Ship Design—Simplification of the design of the ship to adapt it to bridge-shop fabrication was not carried so far by the Merchant Shipbuilding Corporation as by the two other agency yards which

began work at the same time. The vessel is of the ordinary transverse-framed type with frames spaced generally 27 in. The bottom has a small amount of dead rise; the sides are vertical to the upper deck, but the bridge sides have 6-in. tumble-home. For easier fabrication, the parallel middle body was made very long, 50% of the length of the vessel, and the full decks were made flat (without sheer), sheer being given only to the forecastle and poop deck and the bulwarks. Transversely, the second deck has no camber, while the upper deck and the decks above have a straight pitch of 13½ in. to the center line amidships. The floors are, in general, alternately solid and bracket floors, the latter made of 7-in. channel frames with brackets at the center line and at the margin plate. The margin of the tank stop is turned down normal to the shell, and the floors here have no bent parts.

Shipbuilding Plant Compactly Grouped—In the layout of the shipyard, which was briefly sketched in advance of construction in *Engineering News-Record* of Jan. 3, 1918, p. 12, the important rôle assigned to the yard shop finds expression in unusually close grouping of the berths, and of shop and berths. The principal character of the layout, Fig. 2, was determined by certain local conditions, skilfully utilized by the designers to secure economy of construction.

A manufacturing plant, the works of the Standard Cast-Iron Pipe and Foundry Co., stood on the site, and two of the main foundry buildings of the plant were adaptable for use as the fabricating shop of the shipyard. These were long, narrow buildings standing end to end in a line parallel to the river bank and about 400 ft. back of the water; by a short connection between their adjoining ends they could be transformed into a

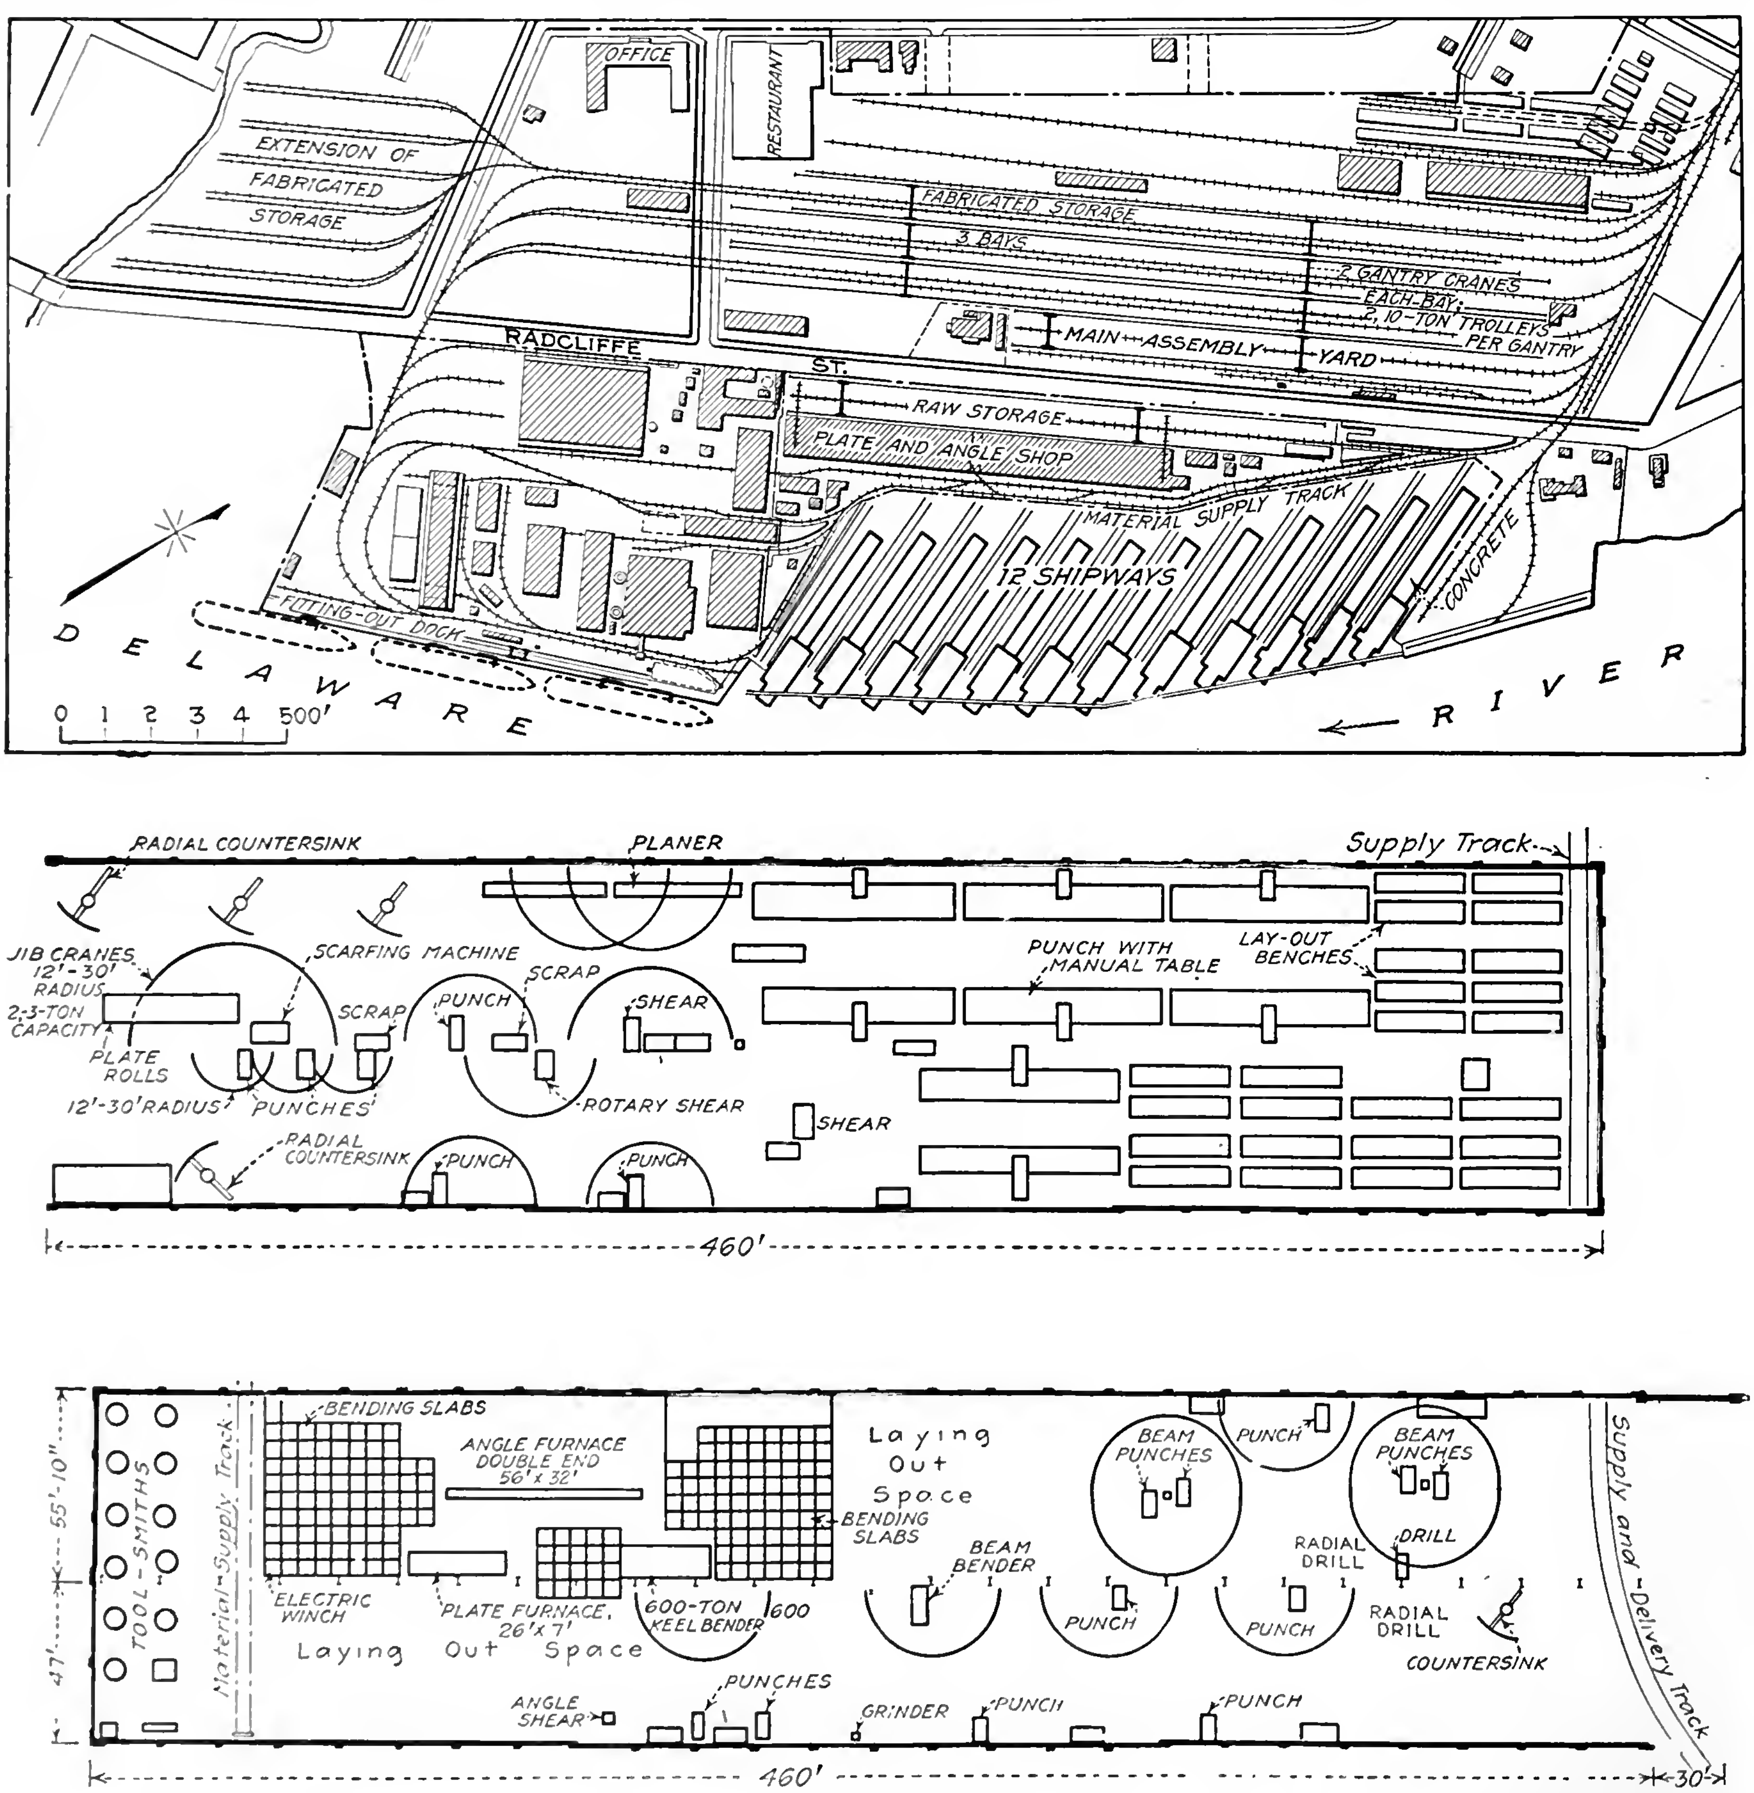

FIG. 2. GENERAL PLAN OF FABRICATED SHIPYARD AND LAYOUT OF PLATE-AND-ANGLE SHOP AT BRISTOL MERCHANT SHIPBUILDING CORPORATION, AGENT FOR EMERGENCY FLEET CORPORATION

single shop building 99 x 970 ft., giving ample space for the required fabricating capacity.

Because of these conditions, permanence of construction was made an objective in the design, at the same time with economy. Since the plant was built at the cost of the Emergency Fleet Corporation, only such expenditures were warranted as were necessary to create a shipbuilding plant of the desired capacity in the shortest possible time. However, as the site gave ideal opportunity for the construction of concrete ways, and the development of the necessary shop buildings was facilitated by the existing buildings of the pipe foundry, a shipyard of permanent character resulted quite naturally. According to the officials of the company, the concrete slab ways have proved entirely successful during the year of operation since shipbuilding started, early in the spring of 1918. There has been no settlement or other injury, and the construction has met all other service requirements.

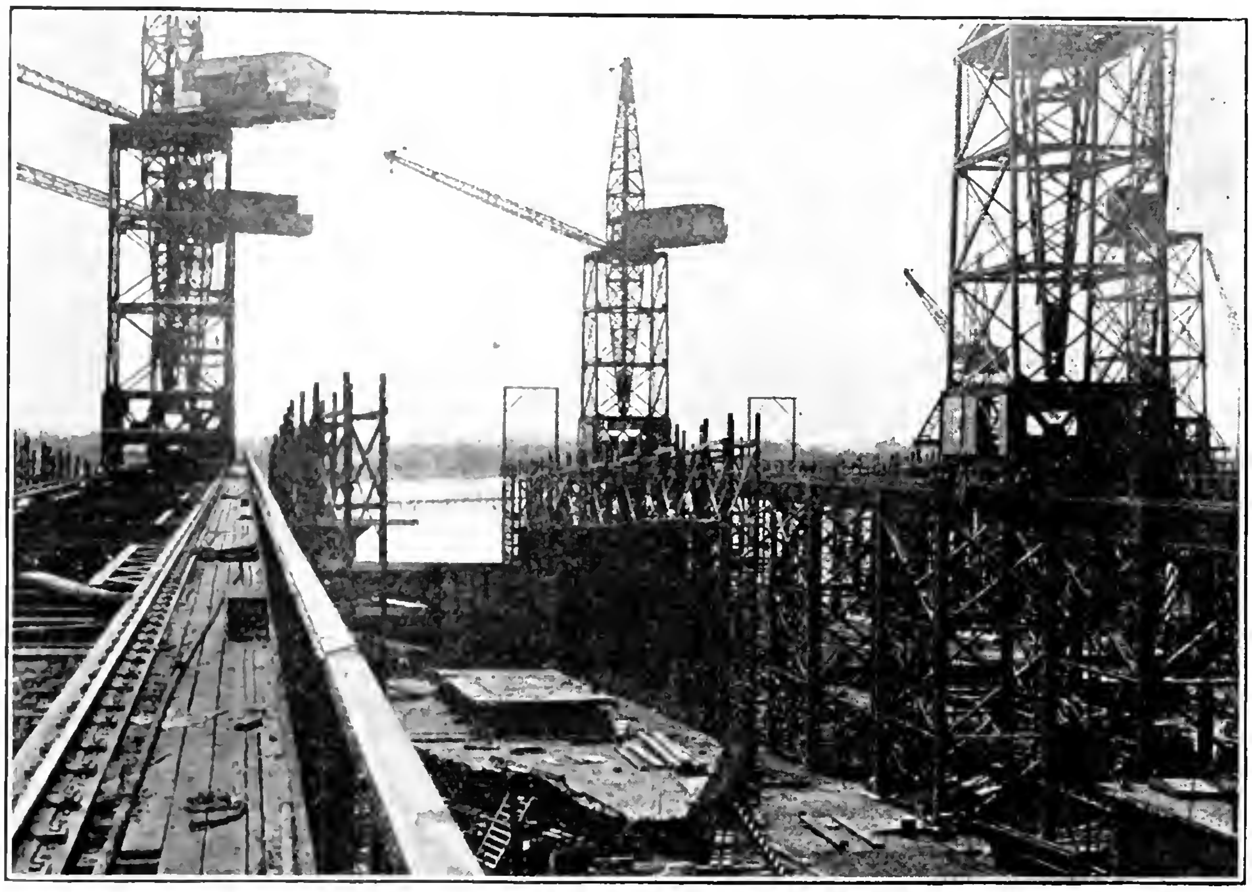

FIG. 3. SHIPBUILDING CRANES AT BRISTOL TRAVEL ON TRESTLES

In design the ways are composite (Fig. 4), consisting in part of concrete slabs 4 ft. thick by 38 ft. wide, and in part of reinforced-concrete beams supported by concrete piles. This is the typical construction above high-water mark. Below high water the ways are timber—wood piles with transverse wooden caps accommodating not only the keel blocks and the launching-way stringers but also abutments for the lateral shores of the standing ways. The sloping ground of the bank required but little grading to adjust it to the launching slope, and the ways were therefore constructed flush with the graded ground surface.

On account of the limited space between the shop building and the river, it was necessary to set the ways at an angle to the shore line in order to accommodate the 400-ft. ship length and have room for tracks and way-head storage space. This skew arrangement proved advantageous in enabling the ship-erection cranes to reach the supply tracks better than would have been the case with ways set square to the shore. The combination of skew and ground slope resulted in a slightly stepped profile in section parallel to the shore, there being a step 2 ft. high from each way to its neighbor; this, however, does not affect the shipbuilding operations.

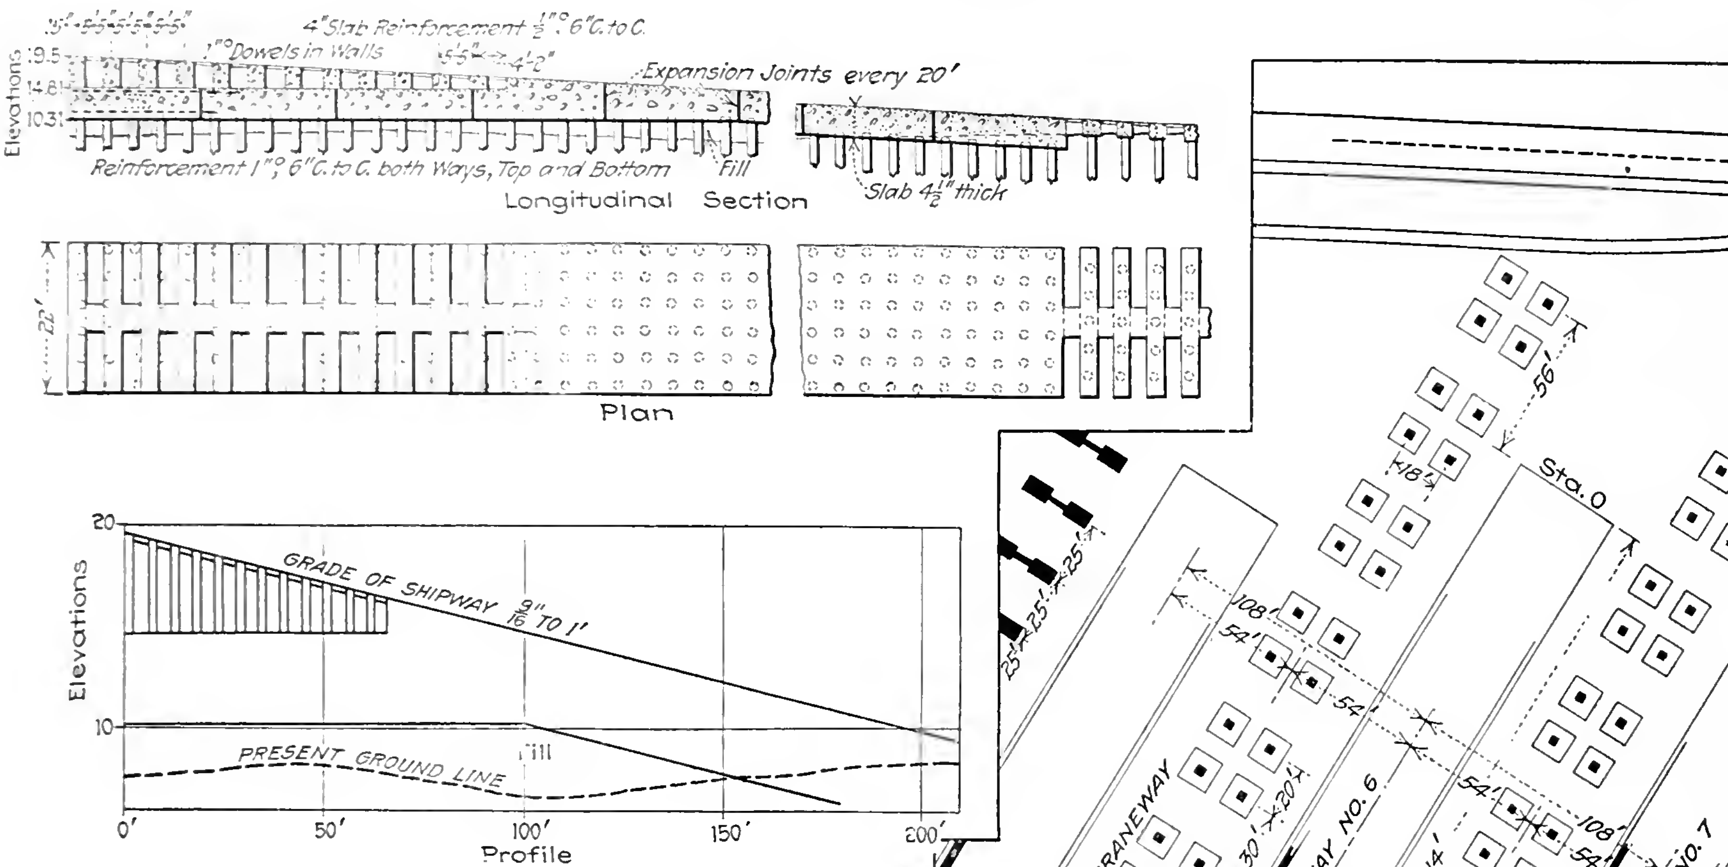
While most of the other fabricating yards adopted fixed derricks for their shipbuilding machines, Bristol chose traveling cranes; and, instead of having longitudinal supply tracks between the ways to distribute material along the length of the ship, it has tracks across the head of the ways only. From these tracks all material is handled down along the berths by cranes. Omitting tracks between the ways made it possible to group the shipbuilding berths very compactly, as the plan, Fig. 2, indicates.

For each shipway two shipbuilding cranes were provided, placed as may be seen in the view, Fig. 3. Revolving jib cranes (Fig. 5) of the type built by the Terry Manufacturing Co., of New York, which had already found use in several shipyards, were chosen as the most suitable for the present service. Nine ways are equipped with these cranes. They have 92-ft. booms, and can lift five tons at extreme reach and 15 tons at 54-ft. reach (hook at center line of ship). The three northerly ways, however, are equipped with locomotive cranes of turntable type, six of which were available for service earlier than the Terry cranes. These machines, of the Brown Hoisting Machinery Co.'s design, have 72-ft. booms and can lift 15 tons at about 40-ft. reach. To make the maximum lifting capacity available practically at center line of ship, the ways in question were spaced 86½ to 97 ft., instead of 108 ft., as are the others.

Trestle supports for the travelers were necessary to give a level track, and it was considered desirable that the cranes should travel on an elevated track for their entire length. The inshore end of the trestle, therefore, was made high enough to give clearance for trucking underneath the bracing. Trucking roads or passageways were at one time contemplated, but they were discarded in the final development of the plan. The space under the trestles is in part occupied by service buildings, and in part used for storage of material awaiting erection, though most such material is held in racks or piled at the head of the way.

On account of the angle between the supply tracks and the crane runway, all the cranes are able to take material from cars on the supply tracks. Furthermore, on all the ways except the one at the north end of the group, four cranes can be concentrated on one ship. According to the yard authorities, the crane equipment has proved to be ample in capacity for all requirements.

Storage Facilities—As material fabricated at the bridge shops could not reach the yard in such sequence in timing as to enable the berths to be supplied direct from incoming cars, storage was a vital feature, and



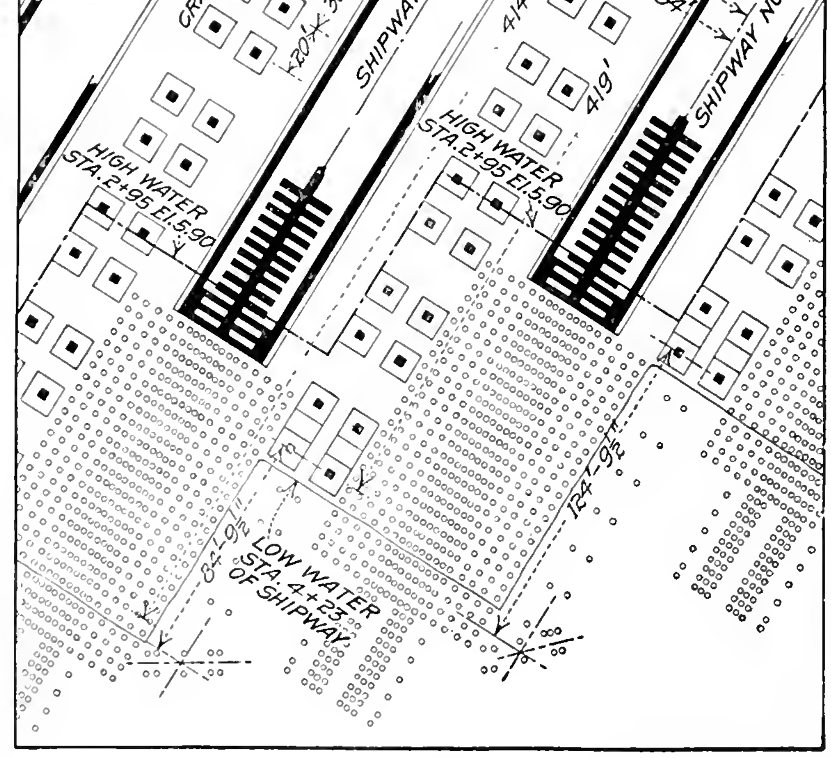


FIG. 4. REINFORCED-CONCRETE SLAB WAYS FLUSH WITH GROUND

the subject received thorough study in connection with the yard working system. The development of storage at Bristol with reference to the system of scheduling, routing and keeping track of material was discussed in *Engineering News-Record* of Jan. 2, 1919, p. 25, and drawings showing the arrangement of the main storage yard were there shown. The original fabricated storage yard was about 200 x 800 ft., but it has since been enlarged. At present the main yard for storing bridge-shop material is 300 x 2200 ft., and an extension of about one-third this size has been provided for. Raw material required by the plate-and-angle shop is stored separately in a narrow yard (100 x 1200 ft.) along the back of the shop building. The main storage yard comprises three parallel bays, 95 ft. wide. Each bay is provided with two gantry bridges equipped with two 10-ton trolleys apiece. Material cars run down the bay on two standard-gage tracks set off center of the width of the bay. Material is piled either side of the tracks, in allotted areas each about 20 ft. long in the direction of the tracks.

The storage yard is laid out with a definite space assigned to each piece in the ship. The problem of laying it out depended on the number of pieces rather than on the tonnage involved, the latter being simply a matter of higher piling.

In the operation of the plant the storage facilities are of central importance, because the whole system has been worked out to provide storage intermediate between shop and ship, and to avoid working direct from shop to ship in any department.

Shop-to-Storage-to-Ship System—Incoming cars of material fabricated at the outside bridge shops run directly into the main storage yard, and are there unloaded, and the material is placed in its allotted storage space by the gantry cranes. An essential piece of work at this point is painting the erection mark on each piece, the shop marks chosen by the bridge shops for their convenience being different from the ship erection marks. From storage, material is drawn on requisitions by any one shipway, according to the needs of the day.

Material fabricated in the yard shop is in part also worked through storage, in order to render the operation of the shop independent of the variations of the berth requirements. This material is of two kinds, templeted and lifted material. The latter, fabricated on special order from the shipway at the time when needed, does not go to storage. Templeted material, however, is worked ahead or on stock, and all this goes to the fabricated-storage yard just as does the incoming bridge-shop material. Similarly, such parts as are fabricated up to a certain point by the bridge shop and have finishing operations, such as rolling, bending or riveting, put on them by the yard shop, go from the fabricated-storage yard (where deposited when unloaded) to the yard shop, and then are returned to the storage yard to await call from the shipways.

Pre-Assembly Highly Developed—In carrying on the routine of minor assembly work, such as that on web frames, stringers, and other curved members, which, because of containing formed work, were not made or were only partly completed by the bridge shop, the Merchant yard during the year has been led to develop pre-assembly to a remarkable extent. An assembly yard 100 x 700 ft. was provided at the start, but it was

later increased to a length of 1300 ft. In addition, a space at the end of the plant north of the ways was available for assembly work.

Facilities for supplying and handling material and suitable tool equipment are features of the large assembly yard. This yard, at one end of the fabricated-storage yard, is spanned by a gantry like those of the storage yard, but has only one longitudinal track. Air-outlet manifolds are placed along the sides at about 20-ft. centers. For the smaller work, such as that on web frames and stringers, a shelter shed about 40 x 40 ft. is provided in the center of the bay, with two air-operated bull riveters. All other riveting is done by pneumatic hammers.

The larger parts that go through assembly, in its present development, are: All deck houses, shaft tunnels, bulkheads, the complete fantail with part of its plating, and the entire keelson with the flat keel riveted to it in lengths of 60 to 100 ft. The splices between these keel sections are ready reamed for final assembly on the keel-blocks. The bow section of the keel is assembled with attached frames. The heaviest members are the large bulkheads and deck houses, weighing 25 tons; these are handled by two cranes. They are assembled in the assembly space north of the raw-material yard, and when completed are loaded on cars by locomotive cranes and shifted along to points within reach of the berth cranes.

In this same assembly space the fitting up and assembling of the keel and keelson girder are carried on. The assembled keel is set up on horses for the full length of the ship, riveted complete in sections 60 to 100 ft. long, and the splices between sections are reamed ready for riveting on the keel-blocks.

This process is carried still further in the case of the bow section of the keel, where, for a length of 11 frames back of the stem, the lower pieces of the frames are riveted to the keelson girder in the assembly yard, thus making a single erection piece out of nearly 30 separate shop pieces.

A still further extension of pre-assembly is contemplated by the corporation. D. D. Smith, assistant general manager, says it is expected that ultimately something like 40% of the hull weight will be involved in the pre-assembly work. This will mean a largely increased amount of shop riveting.

Supply Racks at Head of Ways—Ship erection is carried on from a small way storage at the head of the way, and not from the supply cars direct. Steel plate-racks are provided here, with piling space alongside for floors, frames and similar members. The original intention was to stow all ship material under the crane trestles, but the way-head storage is found more convenient.

Engineering and Fitting Out—The southerly half of the yard area is developed for manufacturing and storage of engineering and ship equipment supplies and for the fitting-out work. Along the river front a timber wharf 1150 ft. long gives berthing space for three vessels engaged in outfitting. Traveling on a track laid on this dock is a large 60-ton luffing-jib crane capable of doing all the heavy hoisting work in placing boilers and machinery on the ship. This crane was described in *Engineering News-Record* of Nov. 21, 1918, p. 937. It is to be supplemented for lighter work by a quick-moving crane, on the same tracks. This will have 15 tons capacity at 54 ft., and 5 tons at 100-ft. radius.

In the case of the ships built at the Merchant yard up to the present, the boilers and turbines have been set in place before launching, and it is intended to continue this practice so long as the machinery supply keeps ahead of ship construction, though the fitting-out crane equipment is capable of setting all machinery at the fitting-out dock. The boilers of the Merchant ships are relatively light. If necessary to install Scotch boilers, however, they would have to be handled at the fitting-out dock. This was one reason for the 60-ton load capacity of the fitting-out crane.

The principal officials of the Merchant Shipbuilding Corporation are R. H. M. Robinson, president; W. T. Smith, vice-president; G. C. Thayer, general manager, and D. D. Smith, assistant general manager. H. E. Frick is the authorized representative at the plant for the Emergency Fleet Corporation.

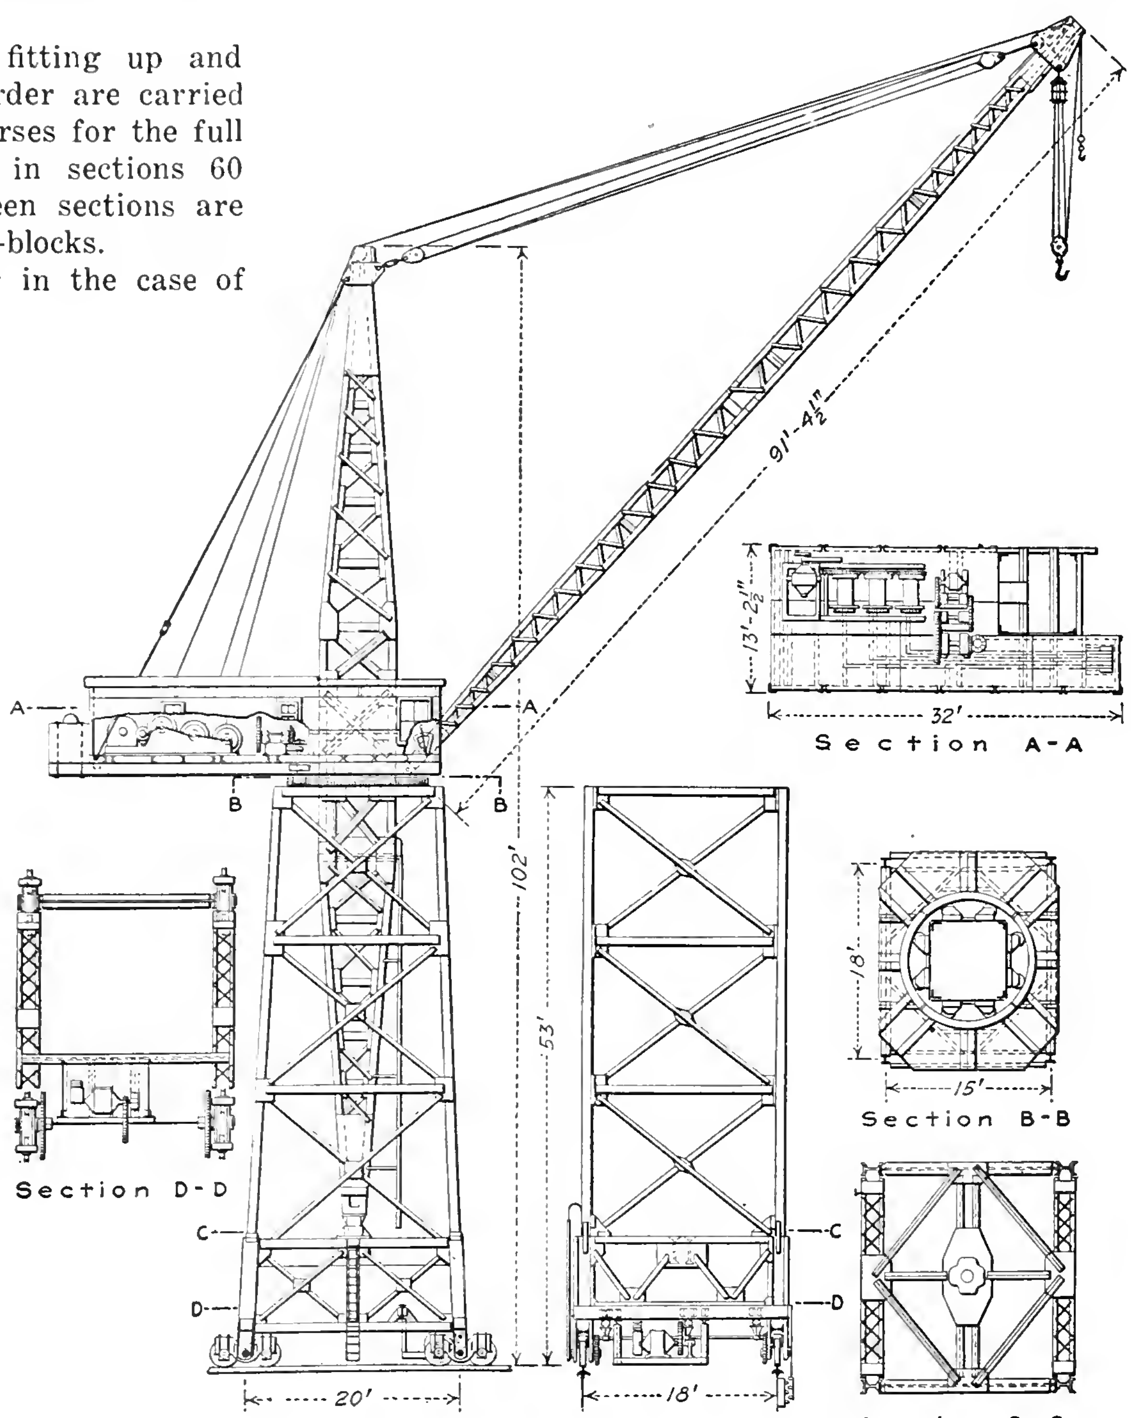

FIG. 5. REVOLVING TOWER JIB CRANES SERVE THE BERTHS

The Construction Division of Our Army: Operation and Maintenance Functions

Organized in Eight Sections—Each Completed Project in Charge of Utility Officer—Plea for Continuance as Independent Unit of Military Establishment

BY GEORGE W. FULLER
Consulting Engineer, New York City

IN A previous article, in *Engineering News-Record* of Feb. 27, 1919, p. 416, the writer sketched the development which established the Construction Division of the Army as an independent organization reporting directly to the General Staff. The magnitude of the work was set forth, and some stress was laid on the type of the responsible organization, embodying as it does the experience and personnel of numerous successful civilian concerns.

In the present article, the writer endeavors to portray briefly the organization of the Building Division and also to set out both the work and the organization of the Operating and Maintenance Division. This more detailed description of those two branches of the Construction Division is of general interest both from the subject matter itself and the bearing which it has on the important question of preserving the division as an adequate entity and with a personnel commensurate with the work still to be performed. There will be set forth in a later issue some maintenance costs and other operating data of interest to engineers engaged in the utility field.

Organization of the Building Division

The principal scheme in the organization of the Building Division is the separation of the construction work into six groups or sections, each under the direction of a section chief whose work embraces one or more types of projects. For example, one section chief handles all ordnance work, another warehouse and terminals, another camps and cantonments, and so on; each section chief has four general assisting units, consisting of an engineering unit, an administrative unit, a materials expediting unit and the unit in charge of estimates and costs. The two latter units act as liaison officers with the Procurement and Engineering Division.

Under each section chief the direction of the field operations again divides geographically under the control of four or five supervising constructing quartermasters, each of whom is responsible for the work of from five to fifteen different projects. The constructing quartermaster, who is the Army's chief representative in the field, communicates with Washington only through his supervising constructing quartermaster, who thereby is enabled at all times to keep in touch with the progress of the work.

Serving all sections and acting as a part of the Building Division there is set up a Requirements Branch, which is charged with all questions dealing with special requirements, including responsibility for the allotment of funds to the various jobs. Furthermore, it has supervision of all requests for funds and statements covering new work which are sent to the Secretary of War or General Staff for approval, and the preparation of necessary reports and statements to the various Congressional and Senate committees and the War College, and of other similar requests for data.

Even after construction is completed and the project put in use, the duties of the Construction Division are by no means finished. Indeed, the operating problem begins before the construction work ends, as the housing of troops commenced, for example, before the camps were finished. Some agency must be set up for a wide range of tasks, such as keeping the streets and roads in repair, operating and maintaining the water and sewerage systems, operating the electric-light and power systems, and making repairs and minor alterations to the thousands of buildings. These are the functions of the Operation and Maintenance branch (officially known since September, 1918, as the Maintenance and Repair Division) of the Construction Division; they have to be exercised at military posts, camps, cantonments, hospitals, terminals, depots and other establishments coming within the jurisdiction of the War Department.

Earliest Efforts at Maintenance and Operation

During 1917 and the early part of 1918, when the Construction Division (or Cantonment Division, as it was then called) was a part of the office of the Quartermaster General, the field forces engaged in operation and maintenance were under the jurisdiction of the local camp quartermasters. These officers were naturally picked for the better known duties of quartermaster—subsistence and personnel supplies, troop transportation, pay, etc.—and their hands were amply full with such duties. Naturally, their experience with operation and maintenance on Army reservations was on the small-post peace-time basis, where the big-cantonment war-time problems never arose. Therefore, the first utility officers placed in immediate charge of cantonment operation and maintenance labored under truly enormous handicaps. There were (1) a deficiency of enlisted personnel; (2) a lack of local appreciation, higher up, of the number of men and the amounts of material demanded by the situation; (3) a slowness in organizing in Washington a centralized operation and maintenance bureau to give adequate help to the local forces. The severe winter of 1917-18 still further added to the burdens of the field forces, and—in the northern cantonments, at least—the camps were kept running only by long hours of arduous duty on the part of officers and men, and by twisting the Army regulation red tape considerably out of its intended form. It is needless here to do more than mention the indefinite and apparently overlapping jurisdictions, during this period, of camp quartermaster, camp surgeon, sanitary corps representatives (medical department) in relation to the utility officers who had to deal also with representatives from numerous offices in Washington.

It was not until the Cantonment Division emerged from under the wing of the Quartermaster General's office that proper development of the operating division was possible. Then the local utility forces were dis-

sociated from the local quartermasters and made directly responsible to the military commander of the reservation and to the division now called the Construction Division, which supervised the work and the funds required therefor.

It was in May, 1918, that utility operations received their first impetus toward adequate expansion. However, the Army deficiency bill, of March, 1918, provided no funds for betterments, and the expansion program proceeded in a restricted way. With the beginning of the new fiscal year, July 1, adequate authorization came for increased personnel and for needed funds. Especially in view of shortages of men and material, much credit is due those who sought to bring methods successful in similar civilian undertakings to the aid of the large Army camps.

Organization for Operation and Maintenance

By the end of 1918 there were under the jurisdiction of the Maintenance and Repair Division the roads, buildings and public utilities in 46 camps and cantonments; 51 hospitals; 66 border stations; 25 supply depots and terminals and 171 regular military posts. For the fiscal year ending June 30, 1919, the funds for its use amount to $62,400,000.

It had as a field force, concerned with the actual operation of its functions at all of these points, 452 commissioned officers and 16,559 enlisted men. The maintenance and repair personnel in the Washington office consisted on that date of 40 commissioned officers and 126 civilians, of whom about 90 have been engaged in work for the entire Construction Division in the blueprinting and photostat rooms.

The organization of the Operation and Maintenance Division parallels the general scheme of the Construction Division of the Army in that it follows so far as practicable the precedents indicated by civilian experience on a large scale. The division is divided into a series of eight branches or sections: (1) Personnel; (2) service; (3) statistics; (4) procurement, which has been combined with the service section; (5) building repair; (6) fire protection; (7) light, heat, power and refrigeration; (8) water and sewerage.

Coördination of Central Office and Field Forces

To keep in touch with these utilities at so many posts and locations requires an efficient and complete central organization. At the same time, such a bureau must not be so highly organized as to impede its own work. The Washington office, in order to maintain intelligent supervision of these utilities scattered all over the United States, must be kept advised as to what is going on, as well as to what are the actual needs. Utilities officers look to Washington for prompt authorization of funds for repairs and extensions, for advice on matters of policy, and for information on countless points which arise.

There are two methods by which the central office acquires information. One is by reports of inspectors, and the other is by the study of the reports of the utilities officers themselves. A utilities officer is busy and has little time for the preparation of reports. Accordingly, only monthly statements, containing information in the most concise and brief forms, are required. These reports are usually headed by a summary outlining matter of particular importance, recommendations as to needs, etc.

When a report is received from a camp or other location, it does not follow the commonly supposed fate of such Government documents, that of being filed away in archives without other than a hasty examination. It is carefully studied for two purposes; (1) To find out what has occurred during the previous month at the job, and (2) to analyze the proposition better from the viewpoint of efficient and economical operation. The report is scrutinized by the chiefs of sections or branches, who attach memoranda with any comments or remarks. The officer in charge of the Maintenance and Repair Division then studies the questions of policy, and conditions requiring correction are noted, and communications with instructions are prepared through the aid of the memoranda attached by the section chiefs, and forwarded to the local or camp utilities officer.

At each completed project, in charge of the operating force is an officer selected on his record in civil life in the management of public utilities, holding a position comparable to that of a city manager, but with detailed responsibilities and duties far transcending those of such an official. Indeed, he is a composite of city manager, city engineer, fire marshal, street and building inspectors, managers of municipal water-works and sewers and telephone and electric-supply companies and cold storage, besides being general all-round handyman to whom everybody comes to get anything fixed.

The local organization is military in its character, and was worked out with a view to obtaining the greatest efficiency and the best results with a minimum of personnel and expense. A major is usually placed in charge of this highly important work, and has as assistants a number of commissioned officers of lower grade. For operative and clerical assistants there is a detachment of enlisted men, depending as to the number upon the size of the project, but varying from 300 to 800 in various camps and cantonments.

Each utilities officer maintains in his office a "trouble department"—a desk over which passes every complaint of whatever nature and every request for repairs and replacements. In addition to the written communications received, the number of telephone calls in the trouble department at each camp alone averages several hundred per day. All the work is supervised, coördinated and administered from the Washington office. Refinements and economies are constantly worked out, and their effect is always toward giving the greatest service with a minimum expenditure of public funds. The Maintenance and Repair Division of the Construction Division's office is really a huge service organization operating for the benefit of over a million persons, and designated to supply them with every convenience and comfort incident to their existence as soldiers stationed at Army posts.

Future Work of the Construction Division

The writer will endeavor to set out below a brief consideration of some of the factors affecting the future operations of the division and the volume of work to be done in peace times.

When the armistice came in November the Construction Division had under way or completed nearly 1000 contracts for new construction work and was operating utilities at and keeping in repair about 350 military establishments.

While during peace times the demands for so extensive a program will cease to exist, nevertheless, to

provide proper housing for an army of 175,000 men will call for additional permanent construction equal to nearly twice that existing previous to the war.

Undoubtedly, many of the large Army camps will be retained, and the temporary buildings will be improved to provide more comfortable quarters and to give them a more permanent character. This work will extend over a period of years and will total a substantial amount. Then, too, the housing construction on the Mexican border has been of a most temporary and frequently makeshift nature, and much new construction of a more durable type is badly needed there. With our small pre-war army of 70,000 men, the annual building operations were of considerable magnitude, so it is obvious that whether the future Army consists of 175,000 men, or 500,000 men or more, as desired by the advocates of universal military training, the annual new construction for the Army will total many millions. As a matter of fact, there is now proposed one project, a permanent school for the Corps of Engineers, which alone will probably cost from $25,000,000 to $30,000,000. If all other new construction combined for the next fiscal year is only three or four times that of the new school for engineers the total will range from $120,000,000 to $150,000,000.

It has been pointed out in these pages that operation and maintenance and ordinary upkeep form a large undertaking, involving, as they do, investments in structures of a temporary character, whose worth is about $500,000,000, and requiring at present monthly expenditures of about $4,000,000.

Operation and maintenance activities and expenditures will be reduced, but never to a point comparable with the pre-war expenditures. One reason for this is that the pre-war practice of housing troops in widely scattered posts of very small capacity prevented any possibility of training the Army in maneuvers or of mobilizing the men in any way for modern training on a large scale, and the experience of the war has clearly proved the need of maintaining large training centers such as the cantonments provide. Therefore, the operation and maintenance of at least a large percentage of them must continue, as well as many hospitals and also supply depots and terminals representing permanent investments.

Large Expenditures Required

Even though exact figures cannot be foretold, it is clear that even in peace times new construction and operation and maintenance will require large expenditures. It would be unwise and inconsistent with good business to place responsibility for such work in the hands of those unfitted by training or experience to handle these matters, and more especially is this true when it is remembered that there now exists in the Construction Division a highly specialized organization of experienced civilian engineers. These men have made good under unprecedented demands and conditions. No untried agency can handle as efficiently or economically the peace-time requirements.

Some of the lessons of the war stand out strikingly. We were entirely unprepared for war, and most of all in those lines of work of the military establishment where those in responsible positions needed a thorough knowledge of commercial practices and the hard, keen business sense acquired through commercial experience. In the regular military establishment there is no opportunity for the soldier to acquire training or experience akin to that obtained in large civilian organizations. Ordinarily, his training is such as to give him no idea of the value of a dollar or of competitive conditions of production and procurement. From the time he enters West Point the officer is in a measure set aside from commercial pursuits, and if his line of duty brings him in contact with matters of engineering or production he nevertheless loses the value of the practical and competitive circumstances under which his civilian brother labors.

Division Met All Demands

Because it was a civilian organization reinforced with a knowledge, through years of practical experience, of how to obtain materials, transportation and results in the face of adverse conditions, the Construction Division was able to "deliver the goods." The obstacles overcome were not alone those in the field or in the actual construction or operating activities. In fact, the greatest handicap, especially at the start, was the lack of preparedness for the work to be done. Obstacles could not in any large measure be studied in advance, but under the press of immediate needs each problem had to be solved as it arose, and the rapidly increasing scope of the work called for constant changes in the organization. It is fortunate that those experienced constructors who were early called to the division selected certain broad principles of organization which stood the test of constant expansion. Even so, mistakes were made, principally because when the war was started there was no complete scheme of organization susceptible of unlimited expansion and no program for immediately starting construction activities. But the division, nevertheless, met all demands made on it. Praise without stint is due those who put through and were responsible for this great engineering and constructive work, and it should be their reward, as many of them return to civil life, that they go with the knowledge that unquestionably, for the public good, profit has been taken from their successes and their failures and the organization they built shall neither pass out of existence nor lose, by absorption into some other bureaus of the War Department, its entity and that strength which it now has by virtue of the rich practical experience of its civilian engineers and constructors, whether in uniform or not.

There has been suggested a Department of Public Works to handle all construction activities of the various bureaus of the Government. The retention of the Construction Division of the Army would perhaps serve to give an instrument ready at hand in connection with the establishment of such a Department of Public Works.

Pre-War and Present Highway Costs

In 1915 the New York State Highway Department constructed 1073 miles of highways, at an aggregate cost of $11,790,000. At present prices of labor and material but little over one-half of this mileage could be awarded at the above sum, according to the annual report of Edwin Duffey, state highway commissioner. A comparison of the pre-war and present costs of pavements is given in the report as follows:

Item	Cost per Mile: Pre-war	Cost per Mile: Present
Water-bound macadam	$12,000	$18,000
Bituminous macadam	14,000	23,000
Concrete	18,000	28,000
Brick	25,000	35,000

Accurate and Compact Record of City Property

New Castle, Penn., Has System of Maps and Forms Covering Entire City to Record Property Titles and Transfers

A SYSTEM for keeping city records of real estate titles has been worked out in the City of New Castle, Penn., under the supervision of C. H. Milholland, city engineer. It consists of various maps, forms, numbering and index marks to locate readily the data for any particular parcel of land within the city limits. The aim is compliance with the Pennsylvania state law, which requires that such a record be kept in all third-class cities.

In establishing such a system the first step is to make an accurate set of maps showing the street and property lines of the city. A complete survey was made of all streets, and stone monuments, 4 ft. in length and 8 in. square, were placed at each street intersection or street corner. These monuments were also placed so as to be used as bench marks.

As a basis for the preparation of the maps, the city was divided by the city ordinance into 100 sections. The ordinance also provided that each city lot should have a number, so that each lot could be designated as lot No. ——, section ——. Where subsequent subdivision of any lot or tract of land occurs, it is prescribed that each subdivision shall receive the same number, with a letter of the alphabet added to distinguish the various subdivisions.

The scale chosen for the maps was 50 ft. to the inch, this requiring sheets 30 x 48 in. These were made of linen-backed paper. Upon them are shown the center lines of the streets, with bearing and distance in red; stone monuments as small black squares; street lines, lot lines and lot distances in black, and the recorded plot number, if there is one, in blue. Each of the 100 sections has lot numbers running from 1 to 600, and these are shown in red figures. For the purpose of obtaining the information required, the city ordinance provided that each owner of real estate should submit his deeds to the city engineer for registry and prescribed suitable penalties for failure to comply. These original drawings are not shown to or handled by the general public, but tracings of them have been made on which the name of the owner is shown in black, and when there is a transfer of ownership the name is changed.

When deeds are presented, Form 1, as here reproduced, is used to give the owner a receipt. These receipt forms are in a book of about 200 pages. When the deed is returned this receipt must be presented and signed by the owner. Form 2 is used in registering the submission of a deed for entry, and recording the various information as shown. The last column provides for the signature of the owner when the deed is returned. This form is made in a book of 200 pages.

When the registry has been made a book of 600 pages, the headings of one of which are shown in Form 3, is used to record the registry with the proper city lot number, the section number, etc. The form provides for 14 transfers of property. On the map as described above are placed in yellow figures the number of the

RECORD FORMS ARE USED AT NEW CASTLE, PENN., FOR REGISTRY OF ALL REAL ESTATE

registry book and the page; thus 2/25 shows that the lot is recorded in Book 2 on p. 25 of Form 3.

Records of the description of deeds are kept in a steel filing case with 100 files—one file for each of the 100 sections in the city.

Form 4, copy of the deed, is folded and stamped upon the back with Form 5 and placed in its numerical order in the files. Form 6 is stamped upon the deed when it is returned, and is evidence that the law has been complied with. The state law provides that, unless such stamp is found upon a deed, it cannot be recorded by county authorities.

This system of registry may be kept in compact form by having a combination plan case and book rack. At New Castle the plans are kept in 10 drawers, 10 plans to a drawer. The corresponding books are kept in 10 racks placed beside the drawers, the supports for the books being rollers, for easy handling.

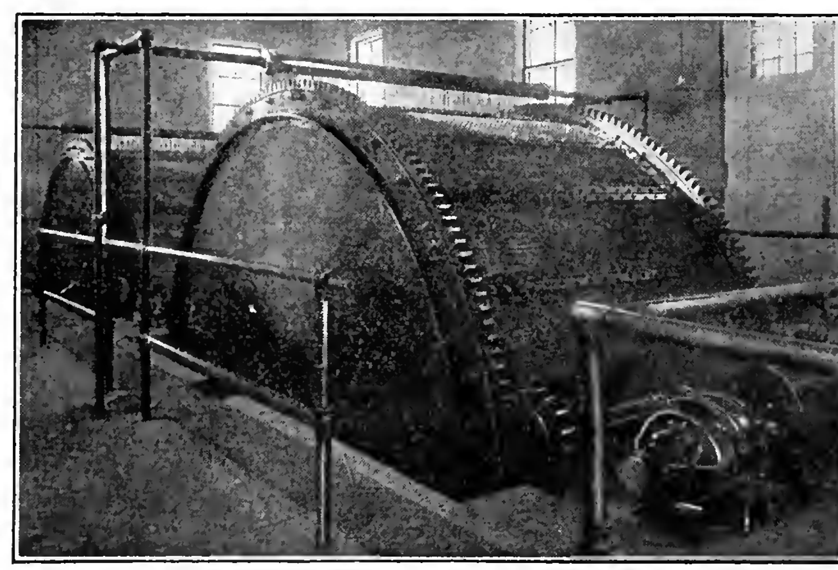
After the installation of the system the council authorized the appointment of a registry superintendent, who attends to the details, furnishes copies of transfers to the city assessors and marks same on their plans. He also acts as clerk in the engineering office, issues street permits, shows plans when requested, etc. Mr. Milholland states that, after operating for some time, these methods have been found quite satisfactory.

Rotary Screens Remove Dirt from Water at St. Paul

Drums Have Shells Built Up of Screen Sections—Wash Water Received by Hopper Is Discharged Through Axle

MOTOR-DRIVEN rotary screens of the drum or cylindrical type are being used for removing vegetation and solid particles from the drinking water at St. Paul, Minn., and, it is reported, are giving satisfaction. They were put in service in November, 1917, and have operated continuously since that time, requiring practically no attention. Two screens are installed, with space for a third. Stationary screens used previously were difficult to clean and required almost constant care.

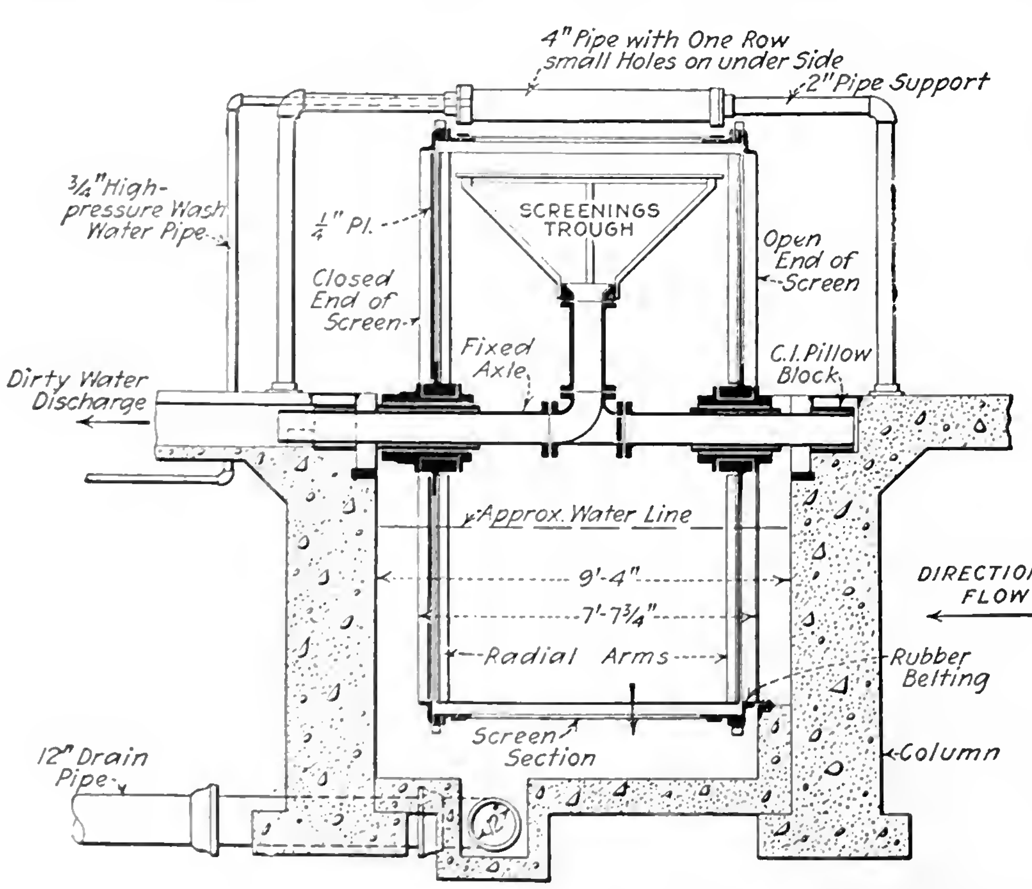
Each screen is about 14 ft. in diameter and 7 ft. long, having a framework of structural steel and being mounted on an 8-in. horizontal shaft. One end is open for the entrance of water, while the other is closed by steel plates. The frame is covered with 24 sections of 80-mesh screens of monel metal, reinforced by a ¾-in. mesh of No. 8 copper wire. The shaft is fixed and the screen drum revolves upon it, being carried by two sets of roller bearings, so that little power is required to drive the screen. For each screen there is a 7½-hp. motor geared to a cross shaft having pinions which engage two circular racks on the screen, as shown, any

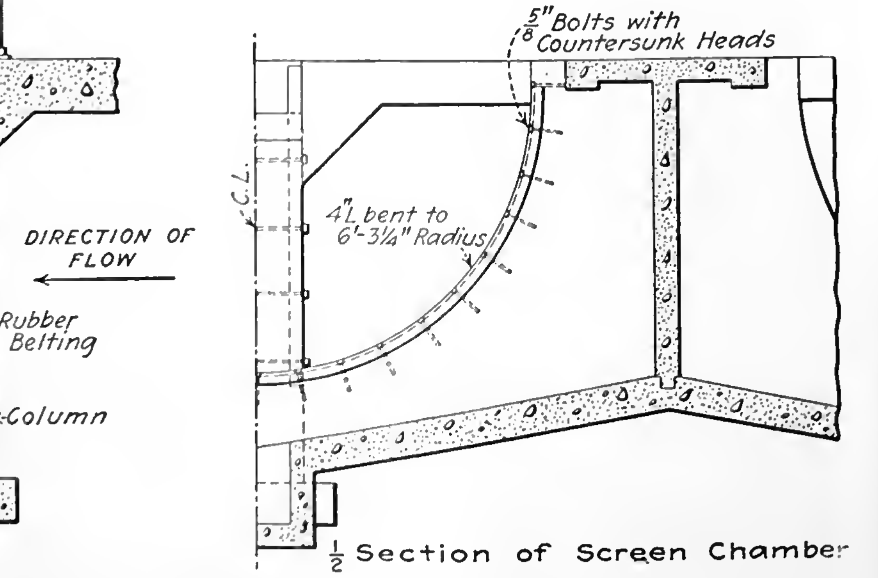


MOTOR-DRIVEN DRUMS SCREEN WATER-SUPPLY

tension being taken up by a differential gear. A speed regulator and two changes in the gears provide for varying speed to suit cleaning required. Normally, the screen makes about one revolution per minute.

The escape of water around the screen drum is prevented by a concrete wall at its open end, with an opening of approximately the same radius as the drum, the joint between the concrete and the metal frame being sealed by rubber belting. Water passes through the screens, leaving dirt and other matter on the inner face. Directly over the top of the drum is a 4-in. perforated pipe for wash water which





WASH-WATER HOPPER IN DRUM DISCHARGES THROUGH HOLLOW AXLE

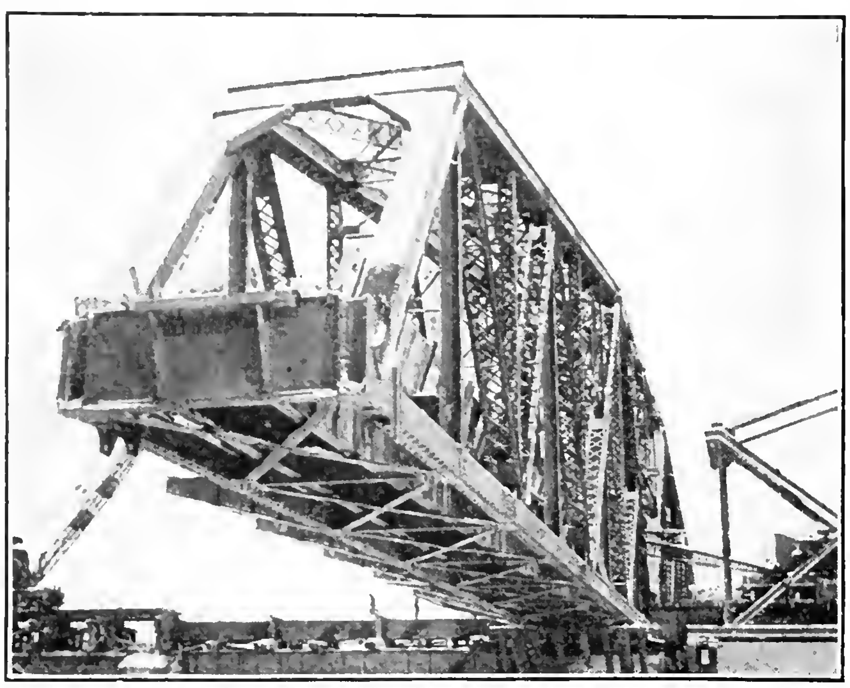
is discharged under 85-lb. pressure. Inside the upper part of the drum is a 4 x 6-in. trough or hopper, which receives the wash-water and dirt. In this way the screen can be cleaned continually with about two gallons of wash water during each revolution. It has been found, however, that the screens operate effectively when the wash water is turned on during one revolution about every 30 minutes. During 1918 the two screens passed about 17,000,000 gal. daily, while the maximum capacity per screen is estimated at 30,000,000 gal. a day. The screen chamber is so built that either or both screens can be shut off and the water passed around them without screening.

These screens were designed under the direction of G. O. House and W. N. Jones, who were, respectively, general superintendent and engineer of the Bureau of Water at that time. They were built by the St. Paul Foundry Co. The screen chamber was designed and constructed by J. W. Kelsey and L. N. Thompson, engineers of the Bureau of Water, all work being done by force account.

Cantilever Erection of Draw in Open Position While Old Draw Serves as Fixed Span

New Swing Span Part of Union Pacific Bridge Over Missouri at St. Joseph—Old Span During Work Carried Traffic

CONSTRUCTION of a new 465-ft. swing span on a new pier, to replace the old 358-ft. span, was the second step in the improvement of the Union Pacific Ry. bridge over the Missouri River at St. Joseph, Mo. The first step was the shifting of three 297-ft. fixed spans longitudinally for a distance of 136 ft. Owing to the condition of the old masonry, it became necessary to build new piers, and as an increase in length of drawspan was imposed by the War Department, it was decided to keep the bridge on its original alignment, building new piers between the old ones. The work of shifting the fixed spans into the new position was described in *Engineering-News Record* of Mar. 13, 1919, p. 550. During the erection of the new drawspan, traffic had to be maintained over the bridge, and this averaged about 75 trains and 400 teams and automobiles daily. River traffic also had to be considered, and for this a temporary lift span was provided. This was not needed, however, as all the work at the draw was done in the winter, while the river was closed to navigation.



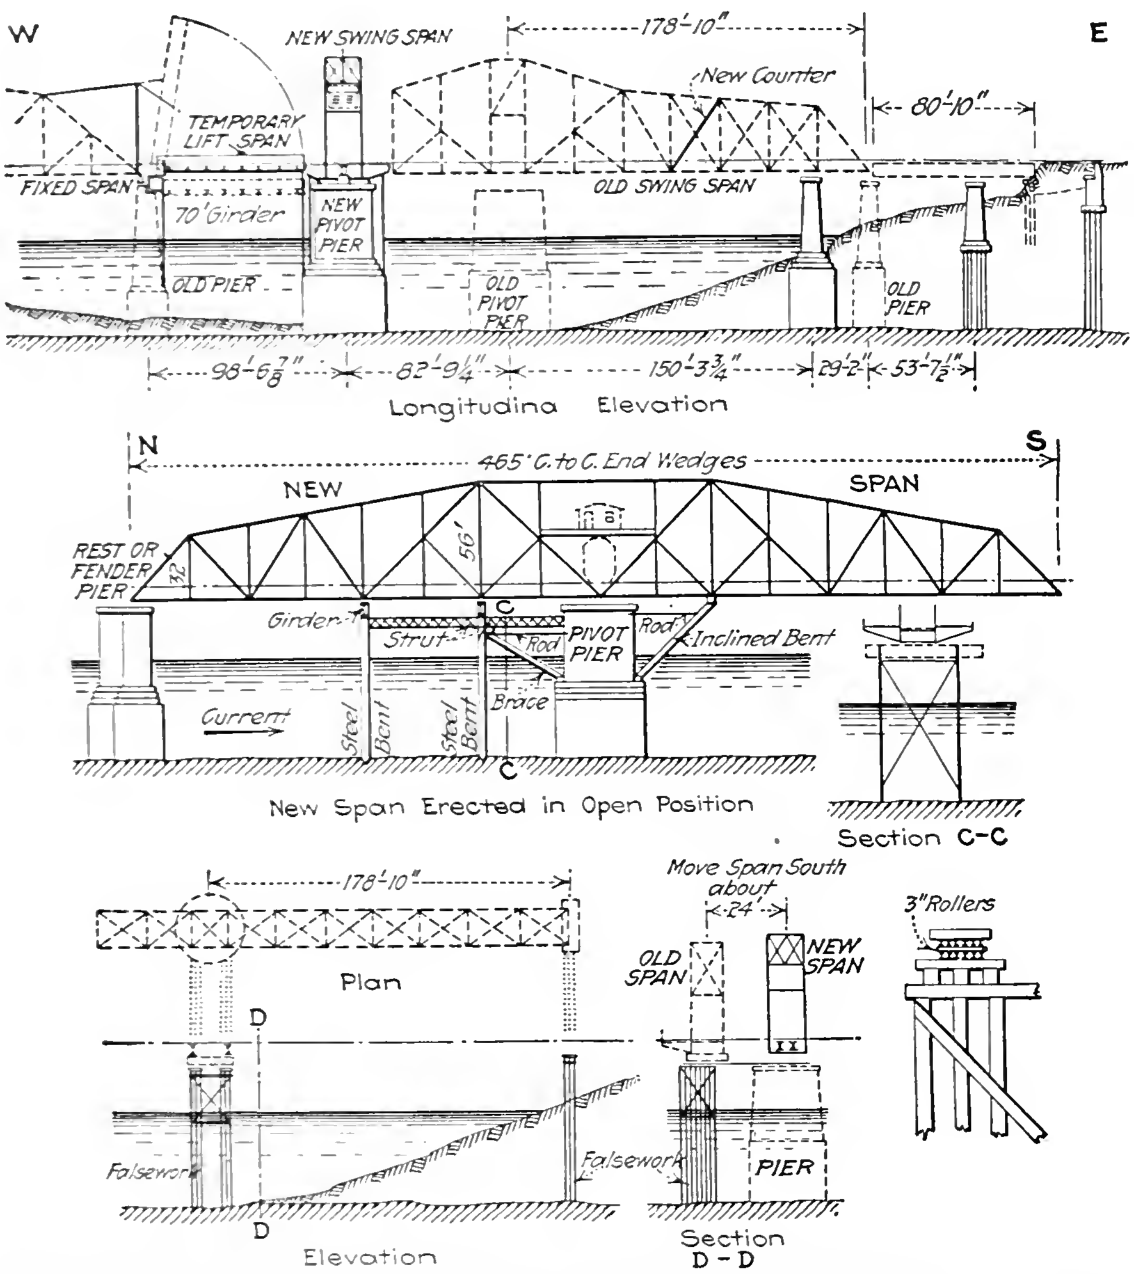
NEW SWING SPAN IS COMPLETED IN OPEN POSITION

Erection of the new drawspan was facilitated by the fact that this span was to be placed on a new pivot pier, in line with, but 83 ft. west of the old span. By erecting it in its open position the only interference was at the point of intersection. The old draw, therefore, was left in place, in its closed position, as a fixed span, but five panels of its west arm were cut off to make room for the new work. The layout of the erection scheme is shown in the accompanying diagrams. Work was commenced as soon as the shifting of the fixed spans had been completed.

A cantilever arm was formed by this shortened or bobtail west arm of the old span, with its end floor-beams only about 2 ft. from the ends of two of the roadway floor-beam brackets of the new draw, these being practically in line with the stringers of the old draw. Blocks bolted to the face of the floor-beam and to the ends of the brackets supported cross-timbers which closed the gap and on which were laid the intermediate ties. To prevent any yielding or lateral movement of the brackets they were supported by a timber bent having its cap cut to the slope of the brackets, as shown in one of the drawings. Removal of the end panels of the old drawspan, as noted above, left an opening between the new pivot pier and the west pier of the old draw. This was utilized for the temporary navigation channel, as shown. A through girder span of 70 ft. was placed here, being pivoted over the old pier and designed to be raised by tackles. Owing to the early closing of the river by ice, however, it was evident that it would not be necessary to operate it. Therefore, when the trusses of the old draw were cut off to permit the erection of the new span in its open position, the floor of the old draw was blocked up on the 70-ft. girders, and traffic was maintained over it without disturbing the track.

To carry the operating track through the new span during its erection, ties were laid temporarily on the drum of that span. The traveler erecting the new span was able to cross this track without disturbing it, by means of rails having slots cut in the webs so that they could be dropped over the rails of the operating track. These slotted rails were removed as soon as the traveler had passed.

As the bridge is raised to a new grade, a temporary



STEEL BENT AND GIRDER SUPPORT PANEL POINT OF NEW DRAW DURING ERECTION OF MISSOURI PACIFIC BRIDGE AT ST. JOSEPH, MO.

inclined runoff was required to connect the new elevation on the bridge with the old grade on shore. This was formed by laying additional ties on the stringers and placing upon these tapered jack stringers which carried the ties of the operating track.

For the new 465-ft. single-track swing span, through trusses of the Warren type are used, these being 56 ft. deep at the middle and spaced 12½ ft. on centers. Floor-beam brackets carry 15½-ft. roadways outside of the trusses. The weight of the span is about 1717 tons, exclusive of the machinery, which weighs 90 tons.

Preparation for work on the new drawspan included the driving of two steel bents, distant 58 ft. and 116 ft., respectively, from the center line of the bridge, to support the first portion of the upstream arm, leaving 116 ft. to be continued as a cantilever until it reached the fender or rest pier. Each bent was composed of two steel piles connected by diagonal bracing having pin connections to allow flexibility in sinking. Each pile was of H-section, composed of three 24-in. 80-lb. I-beams, 78 ft. long, with batten plates over the flanges and having a cast-steel point about 2 ft. long.

Sinking the piles to rock through 35 ft. of sand was assisted by two water jets at 175-lb. pressure and the points were then driven about 2 in. into the solid rock by a five-ton drop hammer. Each pile carried one of the diagonal braces, attached to a pin connection near the foot. This connection permitted the brace to be held in vertical position while sinking, and then to be swung out for attachment to a pin connection at the head of the other pile. As the bents were embedded deeply in the silt, this had to be cleared away temporarily by water jets, to enable the braces to be swung across, as described. The upper half of one brace was made wide enough to allow the other brace to lie within it. A special floating piledriver had to be built to handle these 80-ft. steel piles, each weighing about 28 tons, including the bracing.

Each bent carried a 60-ft. plate girder seated upon shoes on the tops of the I-beams which formed the webs of the steel piles, the two outer beams of each pile being extended above the girder, as shown in one of the photographs. These girders were used later in the new approach. The two girders supported the first portion of the upstream arm of the draw, as noted above. The bents were braced together and to the pier by horizontal steel struts, while the first bent was braced against the pier by a timber raking strut or bent, to resist the thrust of ice and drift in the river. After completion of the work the girders were removed and also the upper parts of the diagonal braces of the bents, the steel piles being then cut off by torches at the ice line, as they were too firmly embedded to be pulled up.

To carry the first lengths of the chords on the downstream side, an inclined timber bent was seated on the footing of the pier, with its top anchored by rods built into the pier. The cap of this bent supported the first panel points of the downstream end of the span. This method of support was planned during the early part

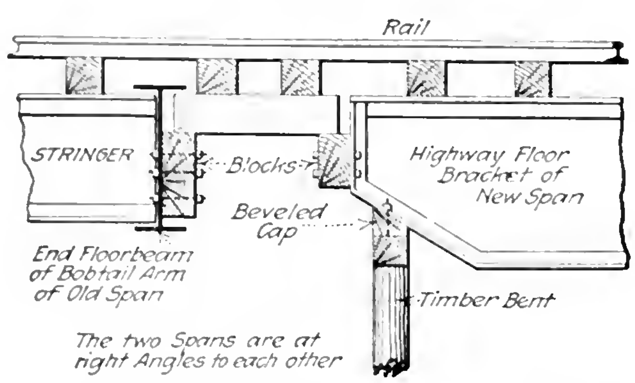
ERECTING CRANE PLACES 80-FOOT 41-TON POST OF NEW SWING SPAN; HIGHWAY PASSES THROUGH PANEL

of the work and the bent was erected, in vertical position, within the cofferdam. With the turntable center erected on the new pier, the derrick car first placed the bottom chords for the four middle panels, the outer ends of these being supported on the steel

bent and inclined timber bent for the upstream and downstream panels, respectively.

Then the panel verticals were erected, followed by the end posts extending from the turntable to the tops of the verticals. Each end post was complete in one piece 80 ft. long and weighing 41 tons. No slings were used in handling them, but hitch plates were riveted at such positions that when attached to the hoisting hook of the derrick the post would swing at approximately its normal inclined position. This facilitated setting this long and heavy member in place. Chord sections weighed from 13 to 18 tons. On the completion of the upstream arm, it served as the anchor for the downstream arm, which was built as a cantilever beyond the inclined supporting bent.

The erection of the end posts at the center of the new draw, with all those members composing the central four panels, was done with a 150-ton locomotive crane that had been built specially for the erection of the long fixed spans at the Metropolis bridge over the Ohio River. The balance of the truss was erected with a



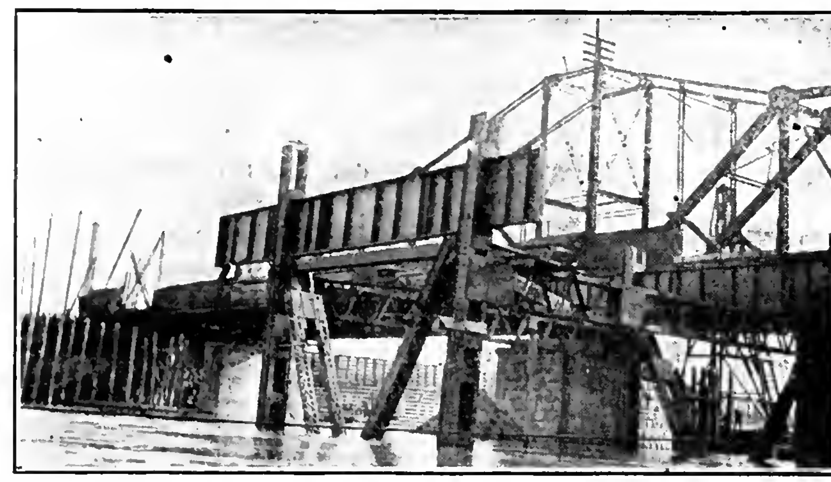
TEMPORARY TRACK CONNECTION BETWEEN THE TWO SPANS

through traveler running on the deck of the new span. This traveler was equipped with a 75-hp. electric hoist. Material was carried out to it on a track supported by the highway floor-beam brackets.

Highway traffic, during erection of the new draw, was carried on the upstream roadway of the old draw, as there was room for teams to pass under the batter posts in the upstream arm of the new span. The old roadway and the brackets on the downstream side were removed, rails being piled against the truss to counterbalance the weight of the upstream roadway. In the 136-ft. opening left by the shifting of the fixed spans for this distance, the track and the roadway were carried on timber pony bents. The main part of each bent rested on blocking on the falsework and carried the railway track, while the projecting cantilever end carried the highway. One of the views shows the crane setting these bents on the falsework.

The removal of the remaining portion of the old span, to permit of closing the new span, was effected by shifting it downstream a distance of 22 ft. This was done on 3-in. rollers laid on rails on pile falsework forming extensions of the old east pier and old center pier. The weight was about 550 tons and the span was moved by means of two nine-part tackles operated by hoists placed on each end of the old span. Both railroad and highway traffic were then operated on the track deck of the new span until the trusses were riveted, this being done to prevent any distortion in the trusses due to outside loading. With the riveting completed, the highway floor was laid on the upstream side.

For dismantling the old span, the floor-beams and bracing were first removed. Then the outer truss was

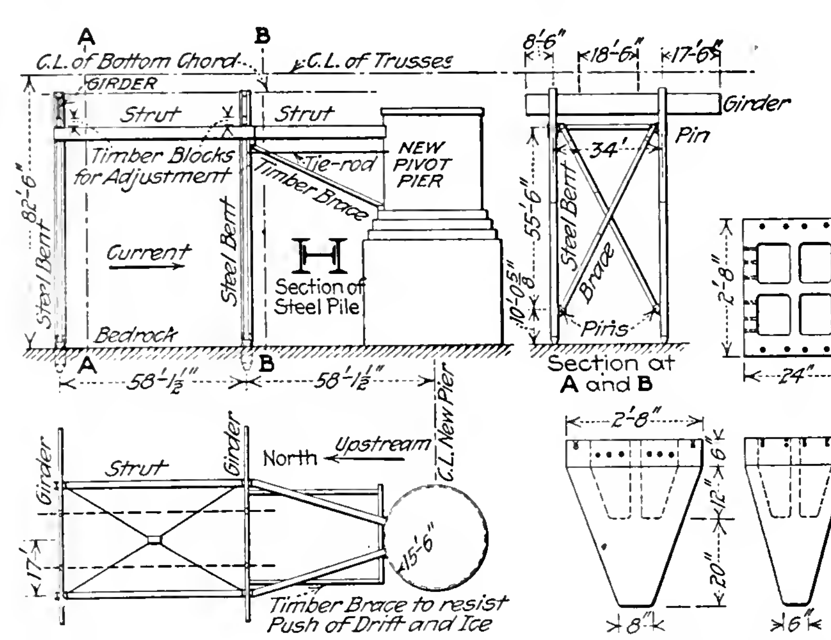


TRAVELER ON CANTILEVER CONSTRUCTION OF SWING SPAN OF ST. JOSEPH BRIDGE

moved back onto I-beam brackets attached to the new span, the latter not being required to open, as the ice still prevented river traffic. The trusses were taken apart by the aid of a derrick placed on top of the east arm of the new span.

When the old draw was rolled out and the new one closed, there was a gap of 28 ft. left between the end of the latter and the old falsework, until the old draw was taken down. Then the 80-ft. girders were rolled 28 ft. endwise to the west, and the new 60-ft. approach spans were erected.

The reconstruction of the swing span and the shifting of the fixed spans were undertaken by the American Bridge Co., under the personal supervision of K. L.



STEEL PILE IS BUILT UP OF THREE 24-INCH I-BEAMS

Strickland, division erecting manager; T. S. Melton, foreman, and A. F. McLane, resident engineer. The work was done for the St. Joseph & Grand Island Railway Co., under the direction of R. L. Huntley, chief engineer of the Union Pacific System, with H. M. Stone as resident engineer, the entire project being under the general supervision of E. E. Adams, consulting engineer of the Union Pacific System.

Immediate National Reconstruction Work in France

Improvements to Navigation of Seine and Various Canals To Be Made, and Highways and Railroads Taken in Hand

By Major Daniel T. Pierce
American Red Cross, Paris, France

FORTUNATELY for France, even while the war was going on there were a certain number of men whose duty it was to prepare for peace. A Ministry of the Liberated Regions was set up when there was scarcely any liberated region to consider. For a year before the signing of the armistice another important bureau was studying plans for the development of France's colonial possessions. At the same time, the Ministry of Public Works was considering a program of public improvements within the Republic to be undertaken immediately after the war. The Under Secretary of State, M. Cels, recently consented to outline these plans as developed up to this time.

This program of the immediate public improvements includes the enlargement and increase of port facilities, canal and road improvement, railroad reconstruction, and many noteworthy projects for increasing the utility of rivers and canals.

Projects for Which Plans Have Been Made

The following outline represents only those projects on which agreement has been reached and for which plans have already been made.

Navigation on the Seine—The work to be undertaken here consists of the reconstruction of the dams at Andressy, Méricourt, Ville-Notre-Dame, La Garenne et Poses, and the removal of the dam at Melun. At each of the waterfall locks of the Seine new locks 660 ft. in length are to be constructed.

Bridges hereafter are to have a clearance of 6 ft. above high-water level, and many tributaries to the river are to be improved and deepened. Certain parts of the navigable channels of the Seine are much in need of rectification, and this work will also be undertaken immediately. The aim is to obtain a channel depth of 15 ft., which will permit bringing up the Seine River to Paris river barges of 2400 tons and seagoing barges of 1800 tons.

North Canal—Prior to the war, extensive improvements of this important waterway were undertaken. These are to be resumed at once, with the intent of making possible the movement of barges of 600 tons instead of those of 300 tons which were the largest barges that could be handled heretofore. The improvements are now to include the repair of the canal of St. Quentin, which repair is an immediate necessity in order that coal from the Northern mines may again reach the region of Paris by canal.

The Rhine Canal—Immediate execution will be undertaken of improvements to permit the use of the canal from the Rhône to the Rhine, throughout its length, by barges of 300 tons. A navigable way from Haute Alsace and the rest of the territory will be assured, handling among other important traffic the potash of the Alsatian region. This program will be extended later on by improvements on the Rhône which is a part of the plan of internal river and harbor work.

Canals of the South—Dredging and rebuilding of towpaths to permit the use of mechanical tractors, and the reconstruction of bridges, are included in the program of improvements for the Canal of the Midi (South) and the laterals to the Garonne. The effects of these improvements will be to increase greatly the efficiency of the southern canals as a means of communication between the ocean and the Mediterranean. Some important improvements on the Loire have also been adopted for immediate execution.

Highways—In the field of road improvements there is a decided inclination to adopt other forms of construction than those which have heretofore proved satisfactory. France obtained her reputation for good roads on the basis of the service given by macadam. This, however, was before the days of war traffic and multitudinous automobiles. Some new plans for road improvement in the territory between Paris and the Marne call for granite block for considerable distances through and beyond the numerous towns and villages. Stone block represents to the Frenchman the ideal of durability under the heaviest traffic, and he is not as yet prepared to change his mind on this point.

Railroads—On the subject of railroad improvement and reconstruction, it is impossible to speak definitely, for the reason that the destruction of the war-zone railroads has been so complete that the effort is simply to put into operating condition as speedily as possible the main lines radiating northeast from Paris. Even the most important of these lines are still in a deplorable condition as to state of roadway and structures, and the available output of steel is totally inadequate to accomplish what must be done before the railroads of the war zone can be restored to pre-war conditions, much less improved as compared with their former state.

American Operation Made Good Impression

Steel bridges will be almost universally adopted and somewhat heavier rail used, for while European railroad authorities are not willing to concede the greater efficiency of the very heavy cars and locomotives preferred in the United States, a very strong impression has been made by the performance of the American equipment imported to France for war purposes, and an even greater impression has been made by the efficiency of operation that prevailed on the lines under the American Expeditionary Forces.

It is evident that the program of internal improvement which must be carried out in advance of the reconstruction of towns and villages will call for a vast amount of material and machinery which France itself cannot supply.

Correction

Several typographical errors appear in the article entitled "Tests Show High Shear in Deep Reinforced-Concrete Beams," by W. A. Slater, in *Engineering News-Record* of Feb. 27, 1919, p. 430. The test beam shown in Fig. 1 was not 26 in. deep but 36 in. as stated in the text. In the shear formula in the first column the coefficient $\frac{7}{8}$ is omitted in the vertical stirrup formula. The second formula in the same line relates to diagonal stirrups. In the second column on p. 431 the coefficient for the deflection formula is 0.0833.

Keep Accurate Costs on War-Time Fee Contract

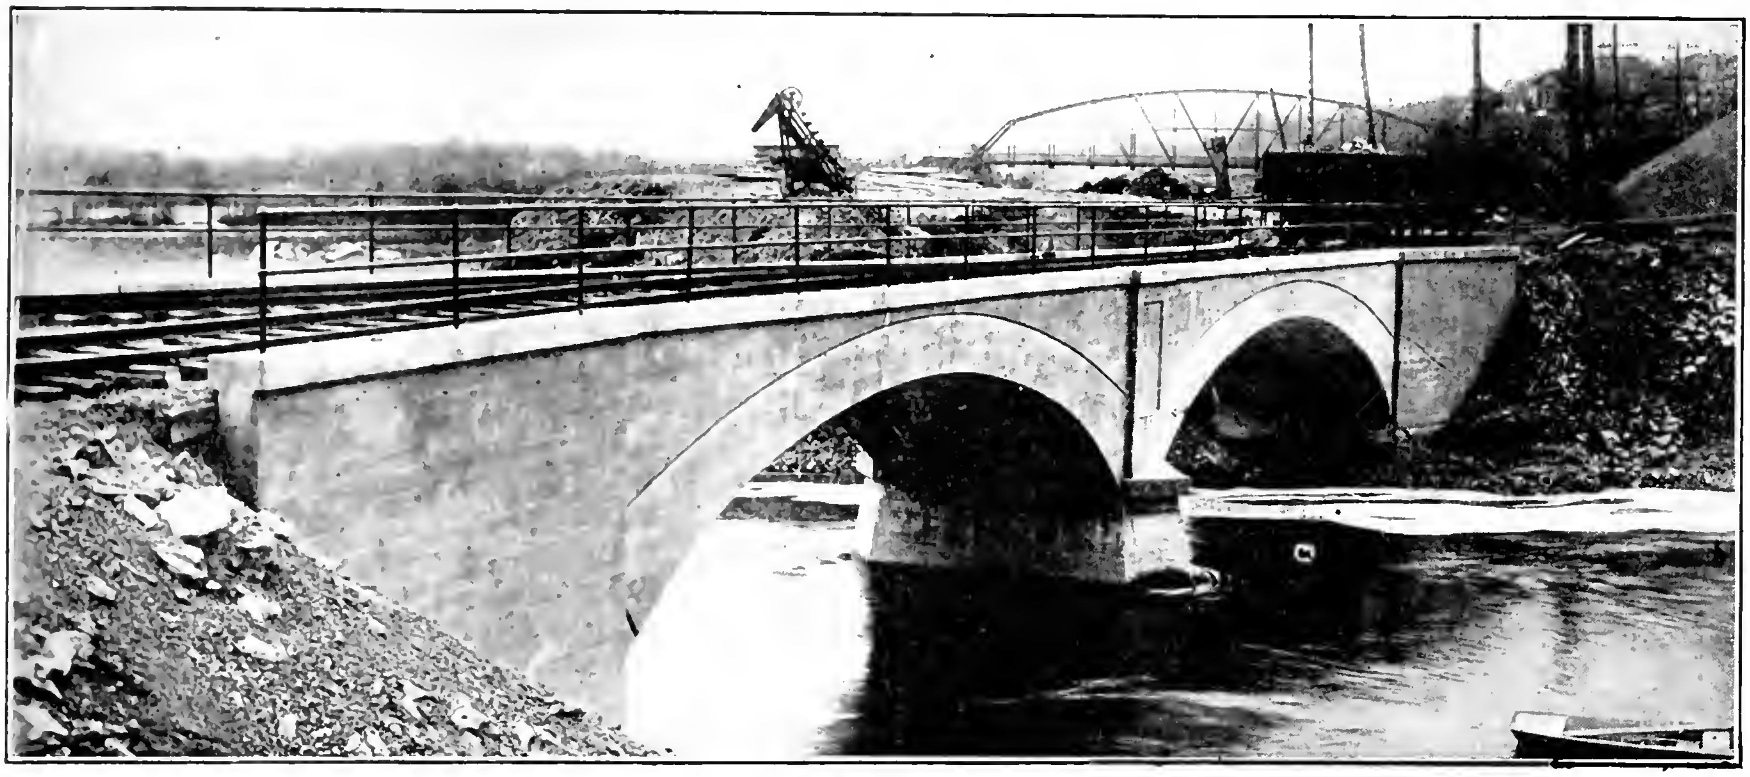
Figures on Small Concrete Bridge Job in Which Instability and Height of War Prices Prevented Lump Sum Bidding

BY FARLEY GANNETT AND J. D. CARPENTER
Gannett, Seelye & Fleming, Engineers, Harrisburg, Penn.

COSTS of construction have changed so entirely during the past three years that the engineer's customary sources of information on costs are useless today, and every new evidence of costs under present conditions is exceedingly valuable. Not only were wages and material prices high, but the efficiency of labor was so low during 1918 that it was not safe to use ordinary standards of work and apply thereto the ratio of old to present wages. The construction of a small concrete bridge in Pennsylvania during the summer of 1918 is therefore interesting on account of the cost-plus-fee form of contract used, and by reason of the fact that careful cost records were kept and worked up, showing accurately actual costs at the high point in the rising prices of 1918 in this section of the country.

The bridge was built for the York Haven Water and Power Co., which operates a 20,000-hp. hydro-electric power plant on the Susquehanna River 16 miles below Harrisburg, Penn. It is a two-span reinforced-concrete arch bridge across the tailrace of an adjoining paper mill, and carries a single-track railroad siding from the main line of the Northern Central R.R. to the power house. Its construction was imperative, as the old trestle which it replaced was unsafe for railroad use, and it was necessary to get heavy machinery into and out of the power house for repairs and replacement. Thus, the bridge had to be built, notwithstanding the high prices.

The contract was let for cost-plus lump-sum fee. The engineer's estimate of cost was $14,880 and the fee was fixed at $1860 or 12½%. Under the contract, if the actual cost exceeded the estimated cost for any reason except increased quantities, no increase was made in the fee, but if the actual cost was less than the estimated cost the owner and contractor shared equally in the saving. If, however, the quantities were increased or decreased, then the fee increased or decreased accordingly. The actual quantities varied so little on the total job that the final estimated cost was $15,000, as against the original estimated cost of $14,880. The actual cost of the bridge was $17,922.17, a little over $3000 more than the original estimate, but one-half of this excess was due to the raise in the labor wage per hour from 35c., when the estimate was made in April, 1918, and 40c. when the work was done. Before the work was let a lump-sum bid was requested from a contractor who was anxious to do the work, but, as his bid was $26,000, it was not awarded to him. This bid evidently included a large allowance for risk on higher wages and cost of materials, as any bid made at that time must have done. The company saved about $6000 by adopting the form of contract used instead of letting it on this lump-sum bid.



CONCRETE BRIDGE BUILT UNDER WAR PRICE CONDITIONS NEAR HARRISBURG, PENN.

The bridge, shown in the view, has two 50-ft. spans with a rise each of 8 ft. and a middle 5-ft. pier. It is 105 ft. from face to face of abutments, 145 ft. from end to end of wing walls and 16 ft. wide out-to-out of side walls. The tracks are carried on an earth fill. The tailrace which the bridge crosses is about 100 ft. wide, with an approximate depth of 7 ft. of water therein and an average velocity of three miles per hour. The old trestle was used to transport materials across the tailrace and to support the arch centering on the new work.

The local labor was all employed in local industries, so colored labor was imported and a bunk house had to be built for them. The only machinery used was a concrete mixer and two pumps. Steam was purchased from the adjoining paper mill. The work was started May 27, 1918, and was finished Sept. 26, a total of 122 days. No great delays occurred, but the progress was slow owing to the great difficulty in getting and keeping labor.

The first work done was the excavation of the east abutment, No. 1, then the central pier and the west abutment. After the east abutment was poured, the concrete was placed in the pier and the east arch, and then the west abutment and arch were poured.

TABLE SHOWING COST DATA ON YORK HAVEN, PENN., BRIDGE, BUILT JULY-SEPTEMBER, 1918

It was necessary to do all excavation inside cofferdams which were mostly of double rows of timber sheetpiling, filled with clay by hand. Money was not spared in making substantial cofferdams; thus the cost of pumping was kept down. The cofferdam enclosing the east abutment was 3 ft. wide, with an average depth of 6 ft. The cofferfill was made with clay borrowed from a pit about 50 ft. distant. The pier cofferdam was also 3 ft. wide, but 10-ft. plank were used, as the water was 7 ft. deep. The wales were first framed and floated to location, where a skeleton coffer was assembled, the whole thing being supported by the old trestle and held in position in the current by wire lines. The skeleton was then sunk, sheathed and filled. Owing to the rough, rocky character of the bottom this coffer had several bad leaks, which were stopped with much trouble.

The coffer for abutment No. 2 was entirely on the bank, although rock was about 5 ft. below water level. A single row of built up tongue-and-groove sheathing was driven, making its cost considerably less than the others. The excavation here consisted of a mixture of cinders and wood scraps, which was wheeled and dumped about 100 ft. away.

One 6-in. centrifugal pump and one 6-in. siphon handled all the water coming through the cofferdams. As an indication of the items which make up the totals on the data sheet, the charge of $252.55 against pumping is distributed as follows: Rental, 88 days, at $1, $88; steam, $61.72; freight and repairs, $31.59; labor setting and moving pumps, $71.24.

After a thorough study of the materials available, it was decided that the gravel from a local deposit, which was offered at $1 per cubic yard of concrete, would be the most satisfactory. The deposit contained about 20% of clean sand under ¼-in.; 60% stone under 1 in.; 20% stone 1 to 3 in., with a few larger stones which were thrown out or used for plums in the 1:3:6 concrete. The gravel, after the sand had been removed, contained from 25% to 30% of voids. Working on the 30% basis, it was decided to use 30% of sand plus 10% of this to make a smoother mixture, or 33% of sand. In actual practice, however, this was found to make a concrete of a stony appearance and hard to work. The amount of sand was then increased to 40% of the gravel, which gave a more satisfactory mixture. A ⅓-yd. mixer was used, 10 revolutions being given the batch before dumping. Enough water was used to make the concrete easily workable, but no water collected in the form. The concrete was wheeled in buggies an average distance of 80 ft. The largest day's pouring was 110 cu.yd., dumping a batch about every two minutes.

The carpenters were local men, experienced in house building but not with concrete forms. The cost of forms ran high, especially in the beginning, on the 1:3:6 concrete.

The bents of the old trestle, used for falsework to support the arches, were cut below the spring line and capped. The centers were wedged 0.1 ft. above grade before concreting. During the pouring the arches settled about 0.15 ft., leaving the center 0.05 ft. low. The bases of the bents were on rock. The reinforcing steel was cut and bent on the job and placed by common labor. A clamshell was used for about 40% of the fill; the remainder was made with wheelbarrows with an average wheel of 80 feet.

The cost data show the total cost of each item, the

TABLE SHOWING UNIT PRICES PAID FOR MATERIAL

(All prices are f. o. b. job)

Lumber, 1-in. plank	$48.00	per M.
Lumber, 2-in. plank	48.00 to 51.00	per M.
Lumber, 6x6 in. to 10x10 in	51.00 to 61.00	per M.
Cement	2.44	per bbl.
Sand	1.50	per ton
Gravel	1.25	per cu.yd.
Reinforcing steel—⅜x⅜ in.	0.038	per lb.
85-lb. rails	75.50	per ton
1¼-in. pipe railing	.90	per ft.

labor cost, material cost, salvage and engineer's estimate. The unit costs are also shown.

The cost of excavation of abutment No. 1 was 75% above the estimate, but that in No. 2 was about 16% less than was estimated. There was, however, considerably more excavation necessary than was contemplated. The pier foundation required no excavation, as the current in the tailrace had washed the rock clean.

The costs of cofferdams, which averaged $11.30 per foot of horizontal length, were fairly near the estimate, while the pumping cost was only half what it was expected it would be. The 1:3:6 concrete in pier and abutments cost nearly 50% more than estimated, while the arch concrete came out very close to the expected cost. The reinforcing steel cost more than expected, largely because of the necessity of paying a higher price to get any steel at all.

The bridge was designed by Gannett, Seelye & Fleming, engineers, of Harrisburg, Penn., and was built under their supervision, with J. D. Carpenter as the resident engineer, by G. W. Ensign, Inc., contractors, of Harrisburg, Penn.

The cost-plus-a-fixed fee contract as illustrated by this bridge contract, wherein any saving over an agreed to probable cost is shared between the owner and the contractor, is not an entirely new form of contract, but its possibilities and equities have hardly been sufficiently appreciated. There is nothing to cause the contractor to attempt to increase costs, as in the cost-plus-a-percentage form, while there is a strong argument, in the way of additional fees, to cause him to do everything to keep costs down. There is no element of risk to the contractor, so he does not have to figure on one job to recoup losses on another. Such contracts will tend toward the employing of contractors who specialize in various forms of construction. Thus, the firm specializing in concrete bridges could be counted upon to build such bridges better and cheaper than a firm specializing in sewer work. Contractors will be employed on their professional ability rather than on their willingness to take a risk.

Under existing laws most municipalities must call for competitive bids and must let the contract to the lowest responsible bidder at a cost which is definitely set in the contract. Thus, it would not seem that much municipal work could be done under the form of contract here discussed until changes are made in the laws. Private corporations and individuals, however, may, and it is expected will, use this form of contract to their considerable advantage.

Efficient Methods of Financing Highway Bond Issues

Problem Has Many Factors Determined by Local Conditions—License Fees Work Well in States Lacking Good Roads

Many different factors, which vary according to local conditions, enter into the problem of determining the proper method of financing highway improvements. Motor-vehicle fees may be used for highway construction or maintenance, according to the condition of the highway system in the state where they are to be applied. In states having no systems, they are particularly adapted to construction purposes, while in states where good systems exist they should probably be applied to maintenance. The above conclusions may be drawn from a paper presented by S. E. Bradt, state superintendent of highways, Illinois, and read by title before the recent convention of the American Road Builders' Association. The following is an abstract of the paper:

The provisions under which state bonds are issued by the various commonwealths are determined by the constitutions, which differ to a considerable extent. They are, however, generally uniform in the requirement that a proposition to issue bonds must be submitted in some form to a vote of the electors of the state.

In addition to complying with the constitution there are many other factors to be taken into consideration, as follows: (1) Present condition of the main roads of the state; (2) amount of mileage to be improved with state funds; (3) general type of the improvement; (4) estimated cost of the improvement; (5) assessed valuation of the state; (6) present rate of taxation; (7) all other sources from which revenue may be derived; (8) amount of bonds to be issued; (9) method of taxation to be adopted in liquidating the bonds that will be just and fair, and (10) maintenance of the roads after construction.

The consideration of these different factors will indicate immediately that the proposition is somewhat complex and that the same provisions will not be applicable to all states. In fact, if the provisions of a bond issue were worked out effectively, based upon local conditions, they would scarcely be the same in any two states. For any states with similar conditions, the Illinois plan of financing bond issues is efficient, equitable and thoroughly practicable. The plan differs from others chiefly in that, while the credit of the state is used to give the bonds stability in the market, the bonds are to be liquidated, both as to principal and interest, from the proceeds of motor-vehicle license fees. In order to bring about a sufficient revenue from this source, the fees which formerly averaged $5 per car have been increased to approximately $10 per car, which is about the amount paid now in every large state.

Every state in the Union has adopted the system of requiring that all motor vehicles be registered and a license fee paid therefor. In many of the states these fees are either in whole or in part turned back to the counties or townships and expended by local officials. It is generally conceded that, very frequently, the funds used upon the roads by local authorities are expended in such a manner as to bring no lasting benefit. In Illinois the money derived from this source has been segregated and was rapidly accumulating in the state treasury.

It is contended by some that these funds should be conserved, to be used exclusively for maintenance, leaving the improvement of the roads to be financed entirely from general taxation. It is undoubtedly true that the taxing of motor vehicles originated because of the damage which they caused to our highways. This was especially true of those stone and gravel roads planned for horse-drawn traffic, and before the days of the automobile. It is also willingly conceded, without

argument, that any state has the right to maintain its roads from motor-vehicle fees. However, Illinois has practically no improved roads to maintain. Its motor-fee collections, based upon the same schedule as other large states, will yield within two or three years from \$5,000,000 to \$6,000,000 annually. The demand for a connected state highway system, requiring a large amount of money, is insistent. Local and state taxes are already so high as to limit the amount that could be raised by general taxation for road improvement, to a sum which would be entirely inadequate. With these conditions in view, the State Highway department conceived the idea of using the accumulating fund as the basis for a construction bond issue.

If Illinois main roads were improved, as are the main roads of Massachusetts, then these motor fees could properly be used for maintenance; or if Illinois had already issued bonds, as has New York, and constructed a system of roads that require \$4,000,000 to \$5,000,000 annually for maintenance, then there probably would be no question as to the necessity for using motor fees for maintenance. However, with a very small percentage of improved roads to maintain, with no bonds outstanding, and with a growing automobile fund sufficient to pay the principal and interest on a \$60,000,000 bond issue and still set aside from the same source an average of \$2,500,000 for maintenance while the bonds are being liquidated, the plan to use this source of revenue appeared to be not only the most equitable, but also the most efficient method.

Whether it is equitable to pay the entire cost of any system of roads from motor-vehicle fees is often questioned. The argument is based upon the theory that road improvement benefits all of the citizens. This is readily admitted, and if the roads in the system were to be the only ones improved, the point would be well taken. In Illinois, however, the 4800 miles to be improved with the bond issue fund comprise only 5% of the total mileage of the state and will carry probably not to exceed 50% of the total traffic. The remaining 95% of the roads will be improved largely through local taxation, so that the general taxpayer will be afforded ample opportunity to pay his share.

Motor Vehicle Owners' Protection

There appears to be apprehension on the part of some people that this method of raising funds will lead to excessive taxation upon the motor vehicle. This danger seems very remote. Motor-vehicle owners today constitute a very large per cent. of the male population, and their relative number is increasing rapidly. Their numbers and influence will be sufficient to protect them against unjust and unsatisfactory legislation.

Finally, if the people are to pass favorably upon a bond issue, which involves a debt and the levying of taxes to meet this debt, then they must be convinced that the method of taxation is fair and just; and the man who is to be taxed must be convinced that he is getting value received from his outlay. In the campaign carried on for the Illinois bond issue, every motorist organization was enthusiastically for the proposition; and, so far as we know, every motor-vehicle owner was equally enthusiastic, although understanding fully that he was to pay the cost. The voters, 35 to 40% of whom are motorists, showed by giving the plan a large majority that they are convinced of its soundness for liquidating the bond issue.

In concluding, it may be stated again that the Illinois plan will not apply to every state in the Union, and is not the panacea for all the financial ills of all the states; but in states where the situation is similar to that in our state, with practically no improved roads, and with a large registration of motor vehicles, it is believed that, with some modifications, it will afford a sound, equitable and efficient method of financing.

Greater Activity Planned for the Hetch Hetchy Project

THE annual report prepared by M. M. O'Shaughnessy, city engineer of San Francisco, outlines recent progress on the Hetch Hetchy project, as well as the extent of activity for the coming year. The project is now in such condition, the report states, that \$600,000 monthly can be expended efficiently in rushing it to completion if the bonds are sold so that this money is made available. During the past year the multiple-arch dam at Lake Eleanor has been completed and has for some time been serving the power house used to develop electrical energy for construction purposes. In addition to the power used on the project the city is deriving an income of \$9000 per month from this temporary power plant, for electrical energy sold in San Francisco.

The most important feature of construction work now under way is the 18-mile tunnel between Early intake and the reservoir for the Moccasin Creek power house. This tunnel is now being advanced from three headings: From Priest Portal the heading has been driven in 1500 ft.; at South Fork an advance of 975 ft. has been made, and at Early intake the heading is in a little more than 1000 ft. Four additional headings will be used later in the work, one at the Priest Portal and two each from the shafts that are being sunk to the tunnel line at Big Creek and Second Garrotte.

The long tunnel is being driven on the day-labor plan at a price lower, the report states, than the engineer's estimate of \$60 per lineal foot. The contractors' bids averaged about \$90 per foot.

Attention will be concentrated on the long tunnel this year, as this will be the limiting factor in the completion of the first unit; i.e., the section above the Moccasin Creek power house, where a total of 66,000 hp. is to be developed under a head of 1215 ft. The longest single section of the tunnel will be the 4½-mile length between South Fork and Early intake, of which about 2000 ft. has already been completed. Six storage-battery locomotives have been purchased for hauling muck out of the tunnels, and an electric mucking machine is also being tried out. A small dam is necessary to complete the reservoir at Priest, the lower end of the long tunnel, and this, together with the penstock and power house, will be finished before the tunnel is ready for service. In case delay in financing makes it necessary to postpone work on the Hetch Hetchy dam, it would be possible to carry the Lake Eleanor dam to a greater height and to divert water from this source in addition to the natural flow of the Tuolumne River for developing power at the Moccasin Creek plant.

The fact that \$1,000,000 worth of Hetch Hetchy bonds were recently sold, and an option on \$8,000,000 more was taken up at the same time, is taken to mean construction work can be pushed rapidly during 1919.

Salt-Marsh Sand Clay as a Road-Building Material

Abounds in Tidal Lands in Texas—Primarily a Mixture of Epsom Salts, Gypsum, Clay and Sand—Economical to Use

ROAD surfacing with a material known as salt-sand clay, taken from the tidal lands of Aransas County, Texas, is being resorted to, with what are reported to be excellent results. The chemical analysis of this material shows that it is essentially a mixture of epsom salts, gypsum, sand and clay. When spread upon the road it hardens and produces a firm surface which has the appearance of sheet asphalt. The information following is contained in a report made to the State Highway Department of Texas by R. H. Phillips, county engineer of Aransas County.

Heretofore the material used for surfacing in this section has generally been oyster shells in various forms and conditions. At some points large shells were used, followed with a coating of finer shells mixed with sand; at other points the final coating was partially disintegrated oyster shells; while at still others the final coating consisted of small, fine shells obtained from banks thrown up on the beach.

The best surfacing locally obtainable has been what is known as "mud shell," taken from reefs in Aransas Bay. The shells, in varying sizes, from ¼ in. up, had voids filled with mud and sand. This fine silica sand, having a coating of silt which acted as a binder, solidifies under traffic and becomes a firm road surfacing. The salty nature of this material holds the moisture and keeps the road compacted.

As these reefs are accessible by wagons only at very low water or by the use of barges, sufficient material was not obtainable to provide for road-building projects. This resulted in experimenting with the material, from salt marshes, which has a composition similar to the mud sand filling in the coarser particles of the shell.

Character of the Material

The deposits drawn from are located in what are known as salt flats, at a distance anywhere from 100 to 3000 ft. from low water at the shore. In some seasons, these flats are covered with salt water for from four to six months. For the remainder of the year they dry out so that the material can be excavated.

There is considerable variation in the composition. The silt content varies in color from black to dark brown and some is even a light yellow. Although called sand clay, the sand largely predominates. The best material for road-building purposes is that which has sufficient silt to coat the grains of sand, thus filling the voids and binding the material when compacted. That considerable salt exists in this mixture is not only shown by the chemical analysis given in the accompanying table, but, as the marshes dry out in the warm weather, crystallization can be noted upon the weeds and grass.

Most of the material is taken out by hand and shoveled into wagons to be hauled to the job. There is generally a film of clean sand over the top, of

CHEMICAL ANALYSIS OF SAMPLE OF SALT-SAND CLAY

Substances Determined:	Per Cent
Silica	6.10

Calcium chloride	2.19
Clay	11.20
Total	99.97

thickness varying from 1 in. to 1 ft. When this is over 1 in. it is generally necessary to skim it off. Wheel-scrapers are used to advantage in many places to dig the material and haul it to the roads. It is necessary to select it so that it will have sufficient binding material. If this is not done, the road surfacing produced will quickly break up and give a condition similar to deep sand.

When first excavated, the material contains considerable water, but it drains sufficiently to be easily handled by the time it reaches the road. The original road crust is not disturbed, unless absolutely necessary, the material being spread evenly over it to bring it to the desired surface. The usual depth used is about 6 inches.

Heretofore the surfacing has been too narrow, as it is found that when wagons get off the road in passing they very soon cut through the crust at the edge and gradually destroy the entire surface. Even 16 ft. is not wide enough, and Aransas County has designated its highways to be 24 ft. wide, with shoulders not less than 2 ft. wide, to be solidly rolled to the same slope as the sand-clay surfacing. Heavy crowns are also a detriment to this type of road. The best crown is about ½ in. to 1 ft. After the surface is spread it is customary to allow the traffic to consolidate it, material being added to fill the hollows which develop as the packing proceeds.

When the road has hardened it has an appearance similar to that of sheet-asphalt pavement. Each night, even in the hottest weather, it absorbs sufficient moisture to keep it compacted and in excellent condition. One of its faults is that it has a tendency to be slippery in wet weather; when this condition is bad it may be overcome by giving the surface a coating of sand or shell. If the crowns are low, the slipperiness has not been found to give much trouble.

The annual wear is estimated at $\frac{3}{16}$ in., which is approximately 73.33 cu.yd. per mile. Add to this 50 cu.yd. per mile for filling depressions that develop under traffic, and figuring the material at 75c. per cubic yard applied, the maintenance cost for the surfacing will run about $100 per mile per year. A small motor truck with a three-blade drag will prove to be an economical means of keeping this road surface in first-class condition, it is said. It is also believed that

an eight-ton roller would be a valuable addition to the maintenance and construction equipment.

Delivering the material upon the road costs about 34c. per cubic yard for a ¼-mile haul, with the addition of about 6c. per cubic yard for each additional ¼ mile. The spreading cost on the average is about 15c. per cubic yard. The information given was supplied by the Texas State Highway Department of which George A. Duren is state highway engineer.

Weights of Steel Roof Trusses by Empiric Formulas

Wide Variation in Results Obtained by Applying Rules to Practical Cases—Comparison With Estimated Weights

By R. Fleming
American Bridge Company, New York

Much ingenuity and study have been spent in the development of empiric formulas for determining the weights of steel roof trusses. Those given below have been brought to a common notation in which

T = weight of truss = WSD;
W = weight of truss in pounds per square foot of the horizontal projection of that portion of the roof supported by one truss;
S = span or distance between centers of supports in feet;
D = distance between centers of adjacent trusses in feet;
P = loading of truss in pounds per square feet of horizontal projection of roof;
U = allowable average direct stress in pounds per square inch (found only in the Thayer formula).

The following list includes the formulas most commonly quoted:

Cambria Steel Co., "Cambria Steel," 11th edition, 1914, for spans of 75 ft. or less.

$$T = 5SD$$

Carnegie Steel Co., "Pocket Companion," 19th edition, 1917, for loads of 40 lb. or more per square foot of ground area:

$$W = \frac{P}{40} \times \frac{1}{5}\left(\sqrt{S} + \frac{S}{8}\right)$$

Fowler, "Specifications for Steel Roofs and Buildings," 5th edition, 1909, for Fink trusses up to 200-ft. span:

$$W = 0.06\ S + 0.6 \text{ for heavy loads}$$
$$W = 0.04\ S + 0.4 \text{ for light loads}$$

Johnson, Bryan and Turneaure, "Modern Framed Structures," early editions: $W = S/25 + 4.0$. In the latest edition, 1916, the Ricker, 1907, formula is used for trusses resting on brick walls, and the Ketchum formula for trusses of steel-frame buildings.

Jones & Laughlin, "Standard Steel Construction," 1916:

$$W = \frac{P}{40}\left(\frac{S}{20} + \frac{12}{D}\right)$$

Ketchum, "Specifications for Steel-Frame Buildings," 3rd edition, 1916, for trusses up to 150-ft. span:

$$W = \frac{P}{45}\left(1 + \frac{S}{5\sqrt{D}}\right)$$

Maurer, "Cyclopedia of Civil Engineering," 1908:

$$W = S/25 + 1$$

Merriman, "Roofs and Bridges," 1888, 1911:

$$T = \frac{3}{4}DS\left(1 + \frac{S}{10}\right)$$

Ricker, "A Study of Roof Trusses," University of Illinois Bulletin, No. 16, August, 1907:

$$W = \frac{S}{25} + \frac{S^2}{6000}$$

Ricker, "Design and Construction of Roofs," 1912:

$$W = \frac{S}{25} + \frac{S^2}{12{,}600}$$

Thayer, "Structural Design," Vol. II, 1914:

$$T = \sqrt{\frac{PD}{U}}\,(4S^2 + 60S)$$

Trautwine, "Engineer's Pocket Book," 1911:

$$W = (0.05 \text{ to } 0.08)S$$

Tyrrell, "Mill Buildings," 1911, for roof load of 40 lb. per square foot of ground area, bays 10 to 20 ft., rafter slope 6 in. to 1 ft. and unit stresses of 12,000 compression, 15,000 tension:

$$W = \frac{S}{20} + \frac{12}{D}$$

The weights of trusses for other loadings and rafter slopes are obtained from a series of curves.

Conclusions regarding empirical formulas drawn from estimated weights of several hundred trusses may prove interesting. Three light Fink trusses resting on brick walls of 40-, 60- and 80-ft. spans, bays 16 ft., load equivalent to 40 lb. per square foot of horizontal area uniformly distributed on the top chord, roof slope 6 in. per foot, weighed 1370, 2550 and 4320 lb., respectively. The estimated weights of three trusses of the Warren type, same span and loading, but roof slope of 1 in. per foot, were 1500, 2900 and 4800 lb. The weights, according to the formulas quoted, for trusses with same spans and loading, are given in Table I.

TABLE I. WEIGHTS OF ROOF TRUSSES—16-FOOT BAYS; LOAD, 40 LB. PER SQUARE FOOT OF HORIZONTAL AREA
W = Weight per Square Foot of Area; T = Weight of Truss

	40-Ft. Span		60-Ft. Span		80-Ft. Span	
Formula	W	T	W	T	W	T
Cambria	5.00	3,200	5.00	4,800	5.00	6,400
Carnegie	2.26	1,446	3.05	2,928	3.79	4,851
Fowler	2.00	1,280	2.80	2,688	3.60	4,608
Johnson, B. & T	5.60	3,584	6.40	6,144	7.20	9,216
Jones & Laughlin	2.75	1,760	3.75	3,600	4.75	6,080
Ketchum	2.67	1,709	3.56	3,417	4.44	5,683
Maurer	2.60	1,664	3.40	3,264	4.20	5,376
Merriman	3.75	2,400	5.25	5,040	6.75	8,640
Ricker, 1907	1.87	1,197	3.00	2,880	4.27	5,466
Ricker, 1912	1.73	1,107	2.68	2,573	3.71	4,749
Thayer	2.75	1,760	3.75	3,600	4.75	6,080
Trautwine	2.00	1,280	3.00	2,880	4.00	5,120
Tyrrell	2.75	1,760	3.75	3,600	4.75	6,080

Again, three Fink trusses of the same span, spacing and slope as before, but with load of 56 lb. per square foot of horizontal projection, an increase of 40%, weighed 1670, 3200 and 5500 lb., respectively. Trusses of the Warren type, roof slope of 1 in. to 1 ft., weighed 1900, 3750 and 6000 lb. The formulas give weights for this loading as in Table II.

The variation—in some cases more than 100 per cent.—of weights obtained from the different formulas will at once be noted. The values obtained from a number of the formulas depend upon the span length alone, and are the same for all loadings. Other formulas make the weight of the truss vary directly as the load, which actual weights show to be an error. DuBois, in "The Strains in Framed Structures," gives a formula taking

TABLE II. WEIGHTS OF ROOF TRUSSES—16-FOOT BAYS; LOAD, 56 LB. PER SQUARE FOOT OF HORIZONTAL AREA

W = Weight per Square Foot of Area; T = Weight of Truss

Formula	40-Ft. Span W	40-Ft. Span T	60-Ft. Span W	60-Ft. Span T	80-Ft. Span W	80-Ft. Span T
Cambria	5.00	3,200	5.00	4,800	5.00	6,400
Carnegie	3.16	2,024	4.27	4,100	5.31	6,791
Fowler	3.00	1,920	4.20	4,032	5.40	6,912
Johnson, B. & T	5.60	3,584	6.40	6,144	7.20	9,216
Jones & Laughlin	3.85	2,464	5.25	5,040	6.65	8,512
Ketchum	3.73	2,393	4.97	4,784	6.21	7,956
Maurer	2.60	1,664	3.40	3,264	4.20	5,376
Merriman	3.75	2,400	5.25	5,040	6.75	8,640
Ricker, 1907	1.87	1,197	3.00	2,880	4.27	5,465
Ricker, 1912	1.73	1,107	2.68	2,573	3.71	4,749
Thayer	3.26	2,082	4.44	4,259	5.62	7,193
Trautwine	2.60	1,664	3.90	3,744	5.20	6,656

into account the load, span, slope and unit stresses, but it is too cumbersome for use. Moreover, it supposes the chords to be of constant section, and neglects the web members, assuming that these two errors compensate.

In fact, as stated by Marburg, in "Framed Structures and Girders," the variables are so numerous that no formula, for the weights of roof trusses, which is at once simple, accurate and generally applicable, can be devised. Such a formula is not necessary. In calculating stresses the weight of the truss is usually so small compared with the weight of the covering, the snow and the wind, that an error in its assumption is negligible.

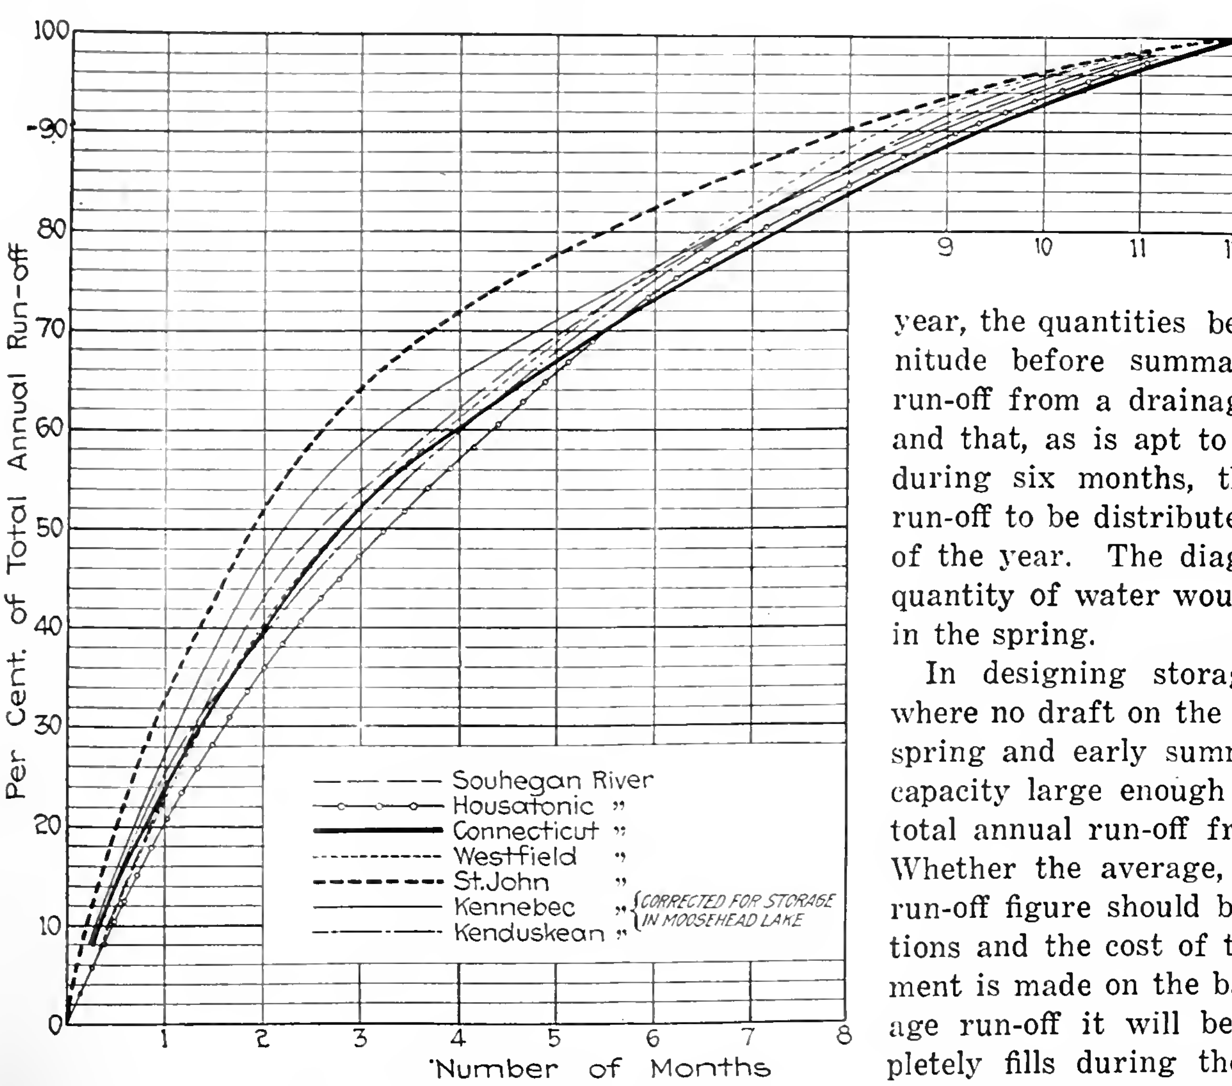
Ordinary steel roof trusses on brick walls with roof slope of 6 in. to 1 ft. and an assumed load of 800 lb. per linear foot of top chord, uniformly distributed, weigh from 30 to 75 lb. per linear foot of span for spans up to 85 ft. For less slopes the weight may be from 5 to 25% more. For different loadings the variation in weight is usually from 25 to 75% of the variation in loading. It should be noted that the personal equation of the designer and the many factors entering into the weights of roof trusses may cause a variation of 5 to 25% in the same truss.

New England Rivers Have Similar Run-Off Characteristics

In Seven Different Rivers Curves Show Half of Total Flow in Three Months and Three-Quarters in Six Months

IN THE analysis of flow records for rivers in various parts of New England the writer has found a marked similarity with respect to the quantity of water which runs off during a few months in the spring and its proportion of the total run-off for the year. The total quantity of water which passes down a river during any calendar month will naturally vary from year to year, and the month of highest run-off during one year may possibly be the month which ranks second or third highest for the next year. However, if records are available for several years so that definite conclusions can be drawn, it will be found that a certain month of the year stands preëminent as being the month which averages the highest run-off.

For the majority of New England rivers this month is April, although for some of the more northern streams May ranks the highest, and for a few rivers draining southern slopes March gives the highest run-off, the average for the one highest month being in the vicinity of 25% of the total run-off for the year. The total for the highest three months, which are usually consecutive, averages over 50% of the yearly total, while six months yield about 75% of the total. These figures are average figures based on several years' records in each case, and apply only to rivers where the flow is not regulated by the use of storage.



DISTRIBUTION OF RUN-OFF OF SEVEN NEW ENGLAND RIVERS IN A 12-MONTHS' PERIOD

The accompanying diagram shows how the cumulative run-off varies with different periods of time during the year, the quantities being arranged in order of magnitude before summation. Assuming that the total run-off from a drainage basin equals a depth of 24 in. and that, as is apt to be the case, 75% of this occurs during six months, there will remain only 6 in. of run-off to be distributed over the remaining six months of the year. The diagram shows that about the same quantity of water would go to waste during one month in the spring.

In designing storage reservoirs in New England where no draft on the reservoir is necessary during the spring and early summer, it is desirable to provide a capacity large enough to hold at least one-half of the total annual run-off from the tributary drainage area. Whether the average, or a greater than the average, run-off figure should be used depends upon local conditions and the cost of the development. If the development is made on the basis of storing one-half the average run-off it will be found that the reservoir completely fills during the spring months five years out of six, and also partially fills a second time in the autumn in some years.

ENGINEERING LITERATURE

A REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Ready Reference Books for the Engineer

By RUTH CANAVAN

Librarian with Metcalf & Eddy, Consulting Engineers, Boston

The accumulation of data and the verification of detail, by research, are necessary and important steps toward the solution of engineering problems. Certain of the most helpful reference works for these purposes are cited in the following paragraphs.

First, there may be mentioned the two useful compilations, "Engineering Index" and "Industrial Arts Index," the former covering the years 1884 to date, and the latter 1913 to date. "Engineering News Index" gives in even more minute detail than does the "Engineering Index" references to the articles in *Engineering News* from 1874 to 1909. [The period from 1910 to the close of March, 1917, when *Engineering News* was consolidated with *Engineering Record* will soon be covered by a volume now in press.—EDITOR.] The annual indexes to "Chemical Abstracts" (1907 to date) cover in a most comprehensive manner the literature on public health, sanitation, the industrial arts, water-supply and sewerage. A cumulative index of the annual indexes for the years 1907 to 1916 has recently been issued, and offers valuable assistance to the research worker.

Other useful cumulative indexes covering professional papers, committee reports and treatises, have been published by the American Society of Civil Engineers (1867 to 1911), the New England Water-Works Association (1882 to 1915), the Society of Chemical Industry (1896 to 1915), the American Society for Testing Materials (1898 to 1912), the American Institute of Electrical Engineers (1884-1910) and the American Institute of Mining Engineers (1871-1904, 1905-1909).

ENGINEERS' HANDBOOKS AND THEIR INDEXES

In seeking information from indexes the many professional "handbooks" must not be overlooked, for most of the compilers appreciate that the value of their books depends largely upon the adequacy of their indexes. For example, a fruitless search of several hours, through textbooks on solid geometry, failed to reveal the method for computing the cubical contents of a peculiar form of ungula; whereas reference to the index of Marks' "Mechanical Engineers' Handbook" led to a prompt solution of the problem. Other handbooks popular in the engineer's library are Merriman's "American Civil Engineers' Pocket Book," Trautwine's "Civil Engineer's Pocket-Book," Frye's "Civil Engineer's Pocket Book," Kidder's "Architects' and Builders' Pocket Book," Ketchum's "Structural Engineers' Handbook," "The Standard Handbook for Electrical Engineers," Foster's "Electrical Engineers' Pocket Book," Gillette's "Handbook of Cost Data," Dana's "Handbook of Construction Plant," Gillette and Dana's "Mechanical and Electrical Cost Data," Walker's "The Building Estimator's Reference Book," and Hool and Johnson's "Concrete Engineers' Handbook."

Many of these handbooks are copiously interlarded with references to articles and reports from which citations were derived, and help set the searcher on the right path. Some of the textbooks and scientific treatises offer similar guidance, by means of footnotes or appended bibliographies.

A card list of bibliographies, arranged alphabetically by subjects, is extremely helpful, and obviates the necessity of retracing ground once covered. Such a list may be so restricted as to include only the results of one's own searches, or amplified to include such bibliographies as those published by the Carnegie Institute, the Concrete Institute, and also those appended to treatises and textbooks.

USEFUL GOVERNMENT PUBLICATIONS

Of great value in engineering research are the publications of the various branches of the United States Government, such as the "Water-Supply Papers," the bulletins and "Professional Papers" of the Geological Survey; the reports and bulletins of the United States Public Health Service; and the contributions of the several bureaus of the Department of Agriculture. Then there are also the reports of the Army engineers and their "Professional Papers," the reports of the Coast and Geodetic Survey, the Lake Survey series, the Weather Bureau reports, the bulletins of the Census Bureau and the many-shelved publications of the Patent Office. Some of these branches issue departmental indexes, but all of the United States Government publications are listed in a "Catalog of the Public Documents of the (various) Congresses, and of all departments of the Government of the United States," issued monthly by the Superintendent of Documents and annually in cumulative form. A "Check List of United States Public Documents, 1789-1909," is also useful as a means of tracing publications that are not very recent.

GUIDES TO ENGINEERING BORDERLANDS

But it is perhaps in the border lands of the other sciences, only occasionally invaded by the engineer, that guidance is most welcome. Chemistry and bacteriology are, as he knows, quite thoroughly covered by "Chemical Abstracts," but a problem sometimes confronts him which demands for its solution a more intimate knowledge of the pathological significance of some factor than the familiar reference works afford, and he resorts to the medical library. Here he may consult "The National Standard Dispensatory" or the "Pharmacopœia of the United States" (two works issued in alternate years), Stedman's "Medical Dictionary," Thorpe's "Dictionary of Applied Chemistry," "A Reference Handbook of the Medical Sciences," an encyclopedia of medicine edited by A. H. Buck in eight volumes, 1885 to 1889;

or for references to the literature on medicine he may refer to the "Index Medicus" (published by the Carnegie Institute) or to the "Quarterly Cumulative Index to Current Medical Literature," published by the American Medical Association.

Again, if the engineer is called upon as an expert witness and wishes to fortify his testimony by references to court precedents, he seeks the law library where, if he wishes the Supreme Court decisions of the various states, he consults one of the branches of the National Reporter System (viz., "The Pacific Reporter," the "Northwestern Reporter," the "Northeastern Report," etc.), or he turns to the "American Digest," which undertakes to cover all decisions in all American courts. "Ruling Case Law" and "The Lawyers' Reports Annotated" also cover cases in all courts to a limited extent, by footnote references illustrative of the precedents enumerated. Textbooks and treatises such as Wait's "Engineering and Architectural Jurisprudence," are similarly helpful. The "Federal Reporter," however, covers only United States Circuit and District Court cases. All opinions relating to public utilities, whether delivered by state commissions or the courts of the various states, are digested in "Public Utilities Reports Annotated" which, unfortunately, only dates back to 1915. Then there are such general reference works as Black's "Law Dictionary," "Words and Phrases Judicially Defined" (an eight-volume encyclopedia), Stroud's "Judicial Dictionary" (in three volumes), Williams' "Law Dictionary" and Wharton's "Law Lexicon."

It sometimes happens also that the engineer is called upon to decide architectural details not usually falling within his province. Reference may then be had to Kidder's "Architects' and Builders' Pocket-Book," to the "Handbook for Architects and Builders," published each year by the Illinois Society of Architects, or to the files of such publications as the *Architectural Review*, the *Architectural Record, House and Garden*, etc., some of these publications being covered by the "Industrial Arts" and "Engineering" indexes, previously mentioned.

Finally, it is useful to know of such very general reference works as "The Readers' Guide," (1901 to date), "Poole's Index" (1882 to 1906), Bartlett's "Familiar Quotations," "The American Year Book," "The International Year Book," the "Biographical Congressional Directory" (1774 to 1911), "Who's Who in America," and "Who's Who in New England," etc.

While the reference works mentioned in the foregoing paragraphs are all well-known and much used, it is hoped that their enumeration may serve to recall some source of information which otherwise might be overlooked, or to give a timely suggestion to the baffled research worker.

Barge Canal Bulletin Ceases Publication

With the January, 1919, issue, the *Barge Canal Bulletin*, which has been published monthly for 11 years under the direction of the New York State Engineer and Surveyor, discontinued publication. According to Frank M. Williams, the present state engineer, the work on the Barge Canal is so nearly completed that it does not seem worth while to continue the publication of the bulletin, which gave publicity to the progress on the various contracts and other items of interest regarding the canal work.

Johnson's Great Book Rewritten

JOHNSON'S MATERIALS OF CONSTRUCTION: Rewritten by M. O. Withey, Associate Professor of Mechanics in the University of Wisconsin, and James Aston, Metallurgist with the A. M. Byers Co. of Pittsburgh. Edited by F. E. Turneaure, Dean of the College of Engineering of the University of Wisconsin. Fifth Edition. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 829; illustrated. $6.

Those who have leaned for many years on J. B. Johnson's great book, "Materials of Construction," will study this new edition with interest and profit, and are likely to adopt it as their reference manual. It is a new work, yet it follows the spirit of the original on a modernized working basis. Such prominent features of the old Johnson as the elaborate descriptive discussion of the varieties of wood, for example, have disappeared, while a 200-page section on cements and concretes properly reflects the great advance in this field made in the 22 years since the appearance of the original work.

Under the editorial guidance of F. E. Turneaure, most of the book was written by M. O. Withey. Six chapters on iron and steel, covering the production of the metal and its constitution, were written largely by J. Aston. Fatigue of metals was handled by J. B. Kommers, and corrosion of iron and steel by O. P. Watts. This collaboration brought to bear on the work a notable wealth of ability and special knowledge. The book clearly reflects this fact; it is of high rank in balance of treatment, in judicious selection of test results and other data, and in critical judgment on the many doubtful or contentious points affecting the properties and testing of materials.

To summarize the contents very briefly: After an introductory section on applied mechanics, of 47 pages, there follow 90 pages on testing machines and testing procedure. An equal space is given to wood, and about 30 pages each to stone and clay products. Cement and concrete have 220 pages, of which 20 pages are devoted to natural cement and lime. Finally, a little less than 300 pages is given to metals, by far the larger part of this space being devoted to iron and its alloys. Cast iron has 40 pages, nonferrous metals 30 pages. The three short but important closing chapters are "Effects of Temperature on Mechanical Properties," 12 pages; "Fatigue of Metals," 16 pages, and "Corrosion of Metals," 18 pages.

Considering the inevitably great bulk of a work of this kind—not far from 1000 pages—and the great and ever extending range of subjects and questions concerned, the technical reader and user of professional works finds himself placed squarely before the question whether compendious treatises can hold their own with sets of specialist books, or whether they may not after all be the preferable thing. Clearly, the compendium must abstract, give boiled-down conclusions, and, in fact, must omit much. Yet there are many features of the present work that would support the argument for the treatise, in view of the excellence with which the work has been done.

It is well remembered that Johnson's original book possessed a strength based as much on his penetrat-

ing judgment of technical questions and discussions and his prophetic vision as on his genius for gathering and selecting data—remarkable as was this latter. This quality of judgment and vision, rare as it is, and necessarily an individual gift, has in a measure a parallel in the present work. True, the author's personality is not so characteristic of the new book as of the old. The times, of course, have changed, and it may be that a greater proportion of the subjective element would not have been wholly advantageous.

Two details of the book may be cited as bearing on the question—which, by the way, is a question to be decided by each prospective user of the book according to his mental leanings. Under the heading of the reason for the tensile test of cement, the book expresses itself very distinctly in advocacy of making the compression test the standard, and states that the reasons for adhering to the tensile test are inadequate. There is obvious conviction in the comment, and a serviceable reminder that conventional methods often lag. Rather different is the attitude of another page. In the treatment of fatigue of metals, after a descriptive review of endurance tests and their results, the text passes without comment to a statement of the use of fatigue formulas in fixing working stresses; it carefully refrains from correlating the tests at high stress ranges with service under low stress ranges. Thus it leaves untouched one of the most delicate and obscure questions in the field of steel structures.

Water-Works and Their Operation

REVIEWED BY CALEB MILLS SAVILLE
Manager and Chief Engineer of the Hartford Water-Works, Hartford, Conn.

CONVEYANCE AND DISTRIBUTION OF WATER FOR WATER Supply. Aqueducts, Pipe-Lines and Distributing Systems. A Practical Treatise for Water-Works Engineers and Superintendents—By Edward Wegmann, C. E., M. Am. Soc. C. E., American Water-Works Association, New England Water-Works Association. New York: D. Van Nostrand Co. Cloth; 6 x 9; pp. 663; illustrated. $5.

Within recent years most branches of engineering literature have received valuable contributions from authors well equipped in theory and practice. Water-supply, however, seems to have been somewhat neglected. This is particularly true of practical water-works operation, which has received little attention since the appearance in 1889 of that pioneer work, "Some Details of Water-Works Construction," by William R. Billings. A notable exception is the very complete "Water-Works Handbook," by Flinn, Weston and Bogert.

Mr. Wegmann's new book is timely. It is divided into three parts: (1) Water Consumption and Hydraulic Formulas (54 pp.); (2) Design and Construction (436 pp.); (3) Maintenance and Operation (143 pp.). In addition, there are five appendixes, three of which are devoted to standard specifications for water pipes, valves and hydrants, structural and boiler steel. Following, there is a brief description of inside fire-protection systems and a reprint of the fire stream tables of the National Board of Fire Underwriters.

The first chapter is principally devoted to data on consumption and waste of water in municipalities. The next two chapters treat very briefly of the hydraulics of water-supply pipes and conduits, and are apparently intended merely for reference. The four chapters on pipes of wood, cast-iron, steel, cement and concrete contain little or no discussion of the merits of the several materials, their applicability to special conditions or their behavior under service conditions. Brief attention is given to stress in pipes due to water pressure, water hammer and temperature. The collapse of empty steel pipes is mentioned. Little is said of stress due to backfill or the care necessary in laying large pipes of comparatively brittle material.

Two chapters on submerged pipes give general descriptions of several under-water pipe crossings. In the two following chapters a number of makes of gate valves, sluice gates, pressure regulators and hydrants are illustrated and described. A discussion of the merits of the several types mentioned, without makers' names, would have added greatly to the value of the book.

The four chapters on intakes, tunnels, aqueducts and service reservoirs, are mostly descriptive and chiefly of historical value, giving little detailed information on design, construction or cost. They appear to have been compiled from reports and technical papers. The several aqueducts of the New York City water-supply are described in considerable detail, and much of the information appearing in the annual reports of the Croton Aqueduct and the Board of Water-Supply is brought together in convenient shape for reference.

In the chapter on service reservoirs, tables of cost of covered reservoirs are given. As these tables were compiled about 20 years ago by Freeman C. Coffin, some caution should be attached to their use at the present time. A very comprehensive compilation of groined-arch data by Prof. John H. Gregory is valuable for use in connection with that kind of construction. The pages given to reinforced-concrete stand-pipe construction are descriptive of many structures which have been built, and a very excellent table is given of the principal data connected therewith.

Tanks of wood and steel are described and some information is given as to design. Under fire protection, classic data are presented regarding the number and size of fire streams required, experiments of discharge and loss of head in fire hose, and a description of the method of conducting flow tests of hydrants. There are good descriptions of the high-pressure water systems in New York, Philadelphia, Baltimore and San Francisco.

Part II closes with seven pages on the various kinds of distribution systems; they give little information as to details and methods required in laying out the work.

Part III is devoted to general descriptions of water-works maintenance appurtenances and appliances. Some brief statements concerning electrolysis, abstracted mainly from reports of the late Prof. A. F. Ganz, are given. Tools and machinery used in pipe work and methods and apparatus used in waste and leakage surveys of water-works systems are next treated. Full descriptions of the various types and makes of meters in use occupy 64 pages. Mention is made of testing apparatus which is furnished by different makers, and a brief discussion is offered regarding results to be obtained. A very interesting and instructive diagram is given as to the average accuracy of ⅝-in. disc meters both new and after service. The author fails to state the conditions under which the data for constructing the curves were obtained.

The last chapter describes various instruments for

recording the height of water in reservoirs, stand-pipes and streams. Most of the standard devices are mentioned.

The book makes some mention of almost every matter connected with water-works operation. The portion on hydraulics is rather too brief for the hydraulic engineer and perhaps not sufficiently elementary for the nontechnical superintendent.

The chapters on design and construction are mostly historical or descriptive. They contain much matter gleaned from published reports on large work and from papers which have appeared from time to time in the technical press and in society transactions.

The portion of the book devoted to maintenance and operation, and especially those parts dealing with appurtenances, seem to be mainly a compendium of information contained in trade publications and advertising literature, rather than an original and distinct contribution to engineering knowledge.

While the classical work of Dexter Brackett, in his water-waste report to the Metropolitan Water Board of Massachusetts in 1903, is well and justly recognized by the author, it is to be regretted that he did not also include mention of the truly remarkable results attained in curtailing waste in this same district which recently has come about principally through the introduction of meters.

The descriptions of water-works appurtenances might well have been supplemented by discussions of the fundamentals of the different types of apparatus and of the limitations of the appliances under certain conditions. This would be of use to water-works engineers and superintendents and would enable them to separate more quickly the grain from the chaff in the salesman's argument.

The author deserves praise for enriching a rather barren field of engineering literature. Water-works superintendents and engineers should be thankful to him for bringing together in one place information concerning so many water-works devices and methods.

For Instructors of Industrial Workers

THE INSTRUCTOR—THE MAN AND THE JOB: A Hand Book for Instructors of Industrial and Vocational Subjects—By Charles R. Allen, Sometime Agent for Industrial Training for Boys and Men, Massachusetts Board of Education, and Superintendent of Instructor Training, U. S. Shipping Board, Emergency Fleet Corporation. Philadelphia and London: J. B. Lippincott Co. Cloth; 5 x 8 in.; pp. 373. $1.50.

According to C. A. Prosser, who in the Introduction states that he is well acquainted with the author, this book is the most important contribution yet made to industrial and trade training. It deals with the vital problem of the selection and training of competent instructors, and it should give employers and foremen a clear and accurate conception of the needs and possibilities of training new workers. It demonstrates that the pedagogy of industrial education has built up a definite content for courses of its own.

The author states that his main purposes are to present a handbook to instructors in industrial plants, and furnish instruction notes for instructor-training courses. The book is the result of actual experience in training over 1000 shipyard instructors. A fairly complete idea of the contents is given by the titles of the nine parts into which the book is divided: Training in the Plant; the Analysis and Classification of Trade Knowledge; Establishing an Effective Instructional Order; Putting it Over; Methods of Instruction; Lesson Planning; Instructional Management; Organization for Training in Industry; The Use of This Material in Instructor-Training Courses.

Perhaps the essence of the author's ideas can be expressed in his concept of what instruction really is, and his proposed tests of effective instruction. He maintains that telling is not instruction, drilling is not instruction, and showing is not instructing. In every case, true instruction requires thoughtful action on the part of the learner.

The book will be not alone of great practical value to vocational instructors, but also unusually suggestive for teachers of engineering in our colleges and universities, in view of the desire to profit by the war experience which is seen in many institutions.

Sewage Disposal Brought Up to Date

SEWAGE DISPOSAL—By Leonard P. Kinnicutt, late Director Department of Chemistry, and Professor of Sanitary Chemistry in the Worcester Polytechnic Institute; C.-E. A. Winslow, Professor of Public Health in the Yale School of Medicine and Curator of Public Health in the American Museum of Natural History, New York, and R. Winthrop Pratt, Consulting Engineer, M. Am. Soc. C. E. Second Edition, Rewritten. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 547; illustrated. $4.

The present thorough revision is timely, now that a resumption of building sewage-treatment works may be expected after a suspension of activities due to the war. Moreover, the subject is so complex and so many new processes, or variations and changes in old ones, are being continually made, that any book on sewage disposal soon gets out of date. The book first appeared in 1910 and was reviewed at length in this section of *Engineering News* of Nov. 17, 1910, p. 42 of the Engineering Literature Supplement, and also in *Engineering Record* of Nov. 19, 1910, p. 591.

The principal topics which have been expanded or added in the present edition are: Data on disposal by dilution, with particular reference to the investigation and conclusions of the International Joint Commission in its studies of the pollution of the Great Lakes; fine screening, notably experimental and other installations of Riensch-Wurl screens; the present status of Imhoff tanks, with special regard to foaming and related difficulties that have led some engineers to turn away from these tanks of late; the activated-sludge and the Miles-acid processes, both of which have come to the front since the first edition of this book appeared.

The book as a whole is a well-rounded presentation of the development and present status of sewage disposal.

Industrial Democracy Illustrated

MAN TO MAN: The Story of Industrial Democracy—By John Leitch. New York: B. C. Forbes Co. Cloth; 5 x 8 in.; pp. 249. $2.

So much has been written about industrial democracy in general terms that concrete examples afford a pleasing contrast. In this readable volume the author tells how he has helped to establish a number of manufacturing plants on the basis of a community of interest between employers and employees, substituting good-will for ill-will, and coöperation in production and profit for opposing class interests. In brief, the plan is to form a system of industrial government similar to our own Federal Government, with the wage earners as a lower house—all of them in small plants, and representatives in large plants. The Senate is composed of "under-executives, department heads and subforemen, accord-

ing to the size of the establishment." The cabinet consists of the executive officers of the company, with the president of the company acting as chairman.

In place of profit-sharing as commonly practiced, which the author apparently regards as a more or less arbitrary bonus system, the author has introduced at a number of plants a wage increment based "on the efficiency of production." He says: "I take the cost of a unit of production in the period preceding the introduction of industrial democracy and compare that cost with the results after democracy has gone into effect. The gain is distributed as a "collective economy dividend," half to the employees and half to the proprietors. It is paid at frequent intervals, as every two weeks, so as to make it a constantly live issue.

Text on Strength of Materials

Reviewed by Clyde T. Morris
Civil Engineering Department, Ohio State University, Columbus, Ohio

APPLIED MECHANICS—By Charles E. Fuller, S. B., and William A. Johnston, S. B., Professors of Theoretical and Applied Mechanics, Massachusetts Institute of Technology. Vol. II.: Strength of Materials. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 556; illustrated. $3.75 net postpaid.

Considering the fact that very little space is devoted to discussion of tests or the physical properties of materials of engineering, and that centers of gravity and moments of inertia are not included, this volume of 556 pages seems unnecessarily large. In part this is due to the inclusion, at the end of each chapter, of a large number of illustrative problems, which are generally most excellent. The methods of the calculus have been employed throughout, perhaps to a greater extent than is customary, and mathematical refinements of theoretical calculation of stresses are given which are sometimes unwarranted by the assumptions made in the premises as to the properties of the materials and the conditions met with in structures. It should be noted that the authors state in the preface, "As preparation the student should have a knowledge of differential and integral calculus, the principles of statics and dynamics, and the methods of determining the centers of gravity and moments of inertia of areas and solids."

The first chapter is devoted to a discussion of the physical properties of materials, but very little is given on the results of tests. It is followed by a chapter on analysis of stress and strain, a theoretical discussion of the relations of stress intensities acting on a particle in various directions, and including the ellipse of stress. Chapters on uniform stress and uniformly varying stress and stresses in beams give the ordinary theory of flexure. In the discussion of riveted joints no mention is made of the fact that in a riveted joint the friction is the principal resisting medium and that in good work the frictional resistance between the plates is seldom overcome. The chapter on the general theory of flexure includes beams with unsymmetrical cross-sections, acted upon by oblique loads.

Combined stresses, Chapter VII, might better be discussed after Chapter IX, on columns, and should include the article in that chapter which treats of the strut or tie subjected to combined axial and lateral loading. The treatment in Chapter VII is only approximate, neglecting the effect of the deflection of the member, and might be omitted without loss.

In the chapter on arches and catenaries, after giving the equations for the reactions of arches with two hinges and without hinges, expressed in the form of integrals, the authors develop at great length the reactions for arches of uniform cross-section in which the axis is the arc of a circle. This may be good mental gymnastics for the student, but as these conditions are almost never met with in practice, and seldom attempted, it seems that the work would have been much more valuable if the axis had been made parabolic and the section variable, as in the usual case.

The last chapter, treating of reinforced-concrete beams and columns, contains the derivation of the usual formulas for simple beams, T-beams and columns, based on the straight-line assumption. The system of notation is fairly uniform throughout and conforms in the main to current usage. It would be a great help in using the book as a reference if a table of notation were given to obviate the necessity of searching through the text for the meaning of a letter or symbol.

As a textbook for class instruction, this new work may be satisfactory if supplemented with data and lectures on tests of materials, but as a reference book for the practicing engineer it does not promise to be of any great value.

The Manufacture and Cost of Liquid Steel

LIQUID STEEL: Its Manufacture and Cost—By David Carnegie, F. R. S. E., M. Inst. C. E., M. I. Mech. E., M. I. S. Inst.; Assisted by Sidney C. Gladwyn, Wh. Ex., A. M. Inst. C. E. (Bayliss Prizeman). Second Edition. New York and London: Longmans, Green and Co. Cloth; 6 x 9 in.; pp. 526; with 10 plates and 252 illustrations. $10.

This second edition of the work of a Canadian author, the first edition of which was reviewed in *Engineering News* of Aug. 8, 1913, p. 328, is unchanged except for the addition of five pages on the development of electric steel manufacture in Canada. The new matter consists of a tabular list of the electric furnaces in Canada, which were used, before the war and in 1917, mainly in the manufacture of steel for ingots or steel castings or low phosphorus pig iron. A list of companies manufacturing ferro-alloys and electrodes is added, and a typical charge for shell steel with a statement of electrode consumption concludes the new chapter.

Extending Our Foreign Trade

AMERICAN METHODS IN FOREIGN TRADE: A Guide to Export Selling Policy—By George C. Vedder. New York: McGraw-Hill Book Co., Inc. London: Hill Publishing Co., Ltd. Cloth; 5 x 8 in.; pp. 204.

The extension of American contracting and industrial business into all parts of the world has created a demand for information regarding the best methods of conducting our foreign trade. Among other broad subjects the author of this book discusses the trade policies of the principal nations of the world; the Webb-Pomerene Act and combinations in foreign trade, and a variety of export problems and details, including agents, catalogs, "Heavy Machinery in Foreign Markets," "American Banks Abroad," our merchant marine, "America's Preëminence in Salesmanship," and our tariff in relation to foreign trade.

An Omission Noted

By mischance the name of George Paaswall, New York City, was omitted as the reviewer of Dozal's "Retaining Walls," in our issue of Feb. 20, 1919, p. 390.

PUBLICATIONS RECEIVED

[So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be obtained without cost, at least by inclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or, in case of books or papers privately printed, then to the author or other persons indicated.]

THE CEMENT GUN: Its Application and Uses—By Bryan C. Collier, M. Am. Soc. C. E. Reprint from Paper Read before the Municipal Engineers of the City of New York, Dec. 23, 1918. Allentown, Penn.: Cement Gun Co., Inc. Paper; 6 x 9 in.; pp. 21; illustrated.

CEMENT IN 1917—By Ernest F. Burchard; with a Section on Concrete Ships by Robert W. Lesley. Washington, D. C.. U. S. Geological Survey. Paper; 6 x 9 in.; pp. 37; illustrated.

CHLORINATION OF WATER—By Joseph Race, F. I. C., City Bacteriologist and Chemist, Ottawa; Captain Canadian Army Hydrological Corps; Member of Committee Standard Methods of Analysis, American Water-Works Association. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 158; illustrated. $1.50.

COMPRESSED AIR PLANT: The Production, Transmission and Use of Compressed Air, with Special Reference to Mine Service—By Robert Peele, Mining Engineer and Professor of Mining in the School of Mines, Columbia University. Third Edition, Largely Rewritten. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 485; illustrated. $4.25.

In this edition some chapters "have been entirely rewritten and several have been expanded," the preface states, but the size of the volume has been kept down "by condensation and omission of old matter." The first edition, entitled "Compressed Air Plant for Mines," was reviewed favorably in *Engineering News* of Sept. 17, 1908, the second edition in *Engineering News* of Jan. 19, 1911. The book is divided into two parts; (1) Production and (2) transmission and use of compressed air. Under "Use," rock and hammer drills, coal-cutting and channeling machines, mine pumps and mine haulage and the air-lift pump are described.

DESCRIPTION OF AND GUIDE TO JASPER PARK—Ottawa, Can.: Department of the Interior. Cloth; 7 x 10 in.; pp. 97; illustrated.

Based on a photographic survey by M. P. Bridgland, Dominion land surveyor. Contains handsome halftones, descriptive text and historical notes, all edited by E. Deville, surveyor general of Canada. The park is located in Alberta.

DRAFTING ROOM METHODS, STANDARDS AND FORMS. A Reference Book for Engineering Offices and Draftsmen—By Charles D. Collins, M. Am. Soc. C. E. New York: D. Van Nostrand Co., Cloth; 6 x 9 in.; pp. 149; illustrated. $2.

Notes on drafting-room organization, arrangements; drafting standards, symbols, abbreviations; drawing sizes and methods of marking and filing drawings. Contains also miscellaneous tables of use to mechanical engineers, conversion tables for metric system, weights and measures, decimal equivalents, etc.

DRAINAGE METHODS AND FOUNDATIONS FOR COUNTY ROADS—By E. W. James, General Inspector, Vernon M. Peirce, Assistant Engineer, Charles H. Moorefield, Senior Highway Engineer. Washington, D. C.: U. S. Department of Agriculture, Bulletin No. 724. Paper; 6 x 9 in.; pp. 86; illustrated. 20c. from Superintendent of Documents.

Covers soils, design of ditches and gutters, subdrainage, foundations, loads which can be carried, etc. Contains runoff tables for the capacity of various kinds of drains, and costs of drains and foundations. It should be interesting to all highway designing engineers.

IMPROVEMENT OF THE UPPER MISSISSIPPI RIVER: A Bibliography—By Miss Winifred Gregory, Chief of the Industrial Arts Division, of the St. Paul Public Library. St. Paul, Minn.: Affiliated Engineers' Societies of Minnesota. Paper; 6 x 9 in.; pp. 22.

MANUAL OF INSPECTION AND INFORMATION FOR WEIGHTS AND MEASURES OFFICIALS—By F. S. Holbrook, Inspector of Weights and Measures, Bureau of Standards, Washington, D. C.: Bureau of Standards. Cardboard; 5 x 7 in.; pp. 246; illustrated. Free on request.

MICHIGAN STATE HIGHWAY COMMISSIONER: Seventh Biennial Report, for Two Years Ending June 30, 1918. Lansing, Mich.: State Highway Department. Cloth; 6 x 9 in.; pp. 142; illustrated.

MNEMONIC NOTATION FOR ENGINEERING FORMULAE: Report of the Science Committee of the Concrete Institute; with Explanatory Notes by E. Fiander Etchells. New York. Spon & Chamberlain. London: E. & F. N. Spon, Ltd. Cloth; 6 x 9 in.; pp. 116; illustrated. $2.50.

Radical changes in algebraic symbols and related elements of formula language are proposed in this report. The "mnemonic" feature is illustrated by the author's advocacy of *B* for bending moment. Some of the innovations are of typographical nature and call for unusual fonts of type. Others are the substitution of new letters for quantity symbols now commonly used. The report has a number of appendixes, of which one, entitled "The Inter-Relationship of Nomenology and Symbology," indicates the author's viewpoint. Incidentally, the word "milai" is used as the name of the 1000-lb. unit.

MODEL MAKING: Including Workshop Practice, Design and Construction of Models; A Practical Treatise for the Amateur and Professional Mechanic, Giving Instructions on the Various Processes and Operations Involved in Model Making and the Actual Construction of Numerous Models, Including Steam Engines, Speed Boats, Guns, Locomotives, Cranes, etc. Edited by Raymond Francis Yates, Editor of Everyday Engineering Magazine. New York: The Norman W. Henley Publishing Co. Cloth; 6 x 9 in.; pp. 390; illustrated. $3.

A book for boys and men, this little work is likely to prove inspiring, helpful and instructive. Preliminary to the description of the making of various special models—of engines, hoists, boilers, boats, locomotives, and the like—there are very good chapters on the right kind of workshop, on lathes and drills, on soldering, on hardening and tempering, on the use of abrasives, and on pattern making and electroplating.

MUNICIPAL FINANCES: Report, Mar. 31, 1918; Statistics of Cities and Towns of Iowa. Frank S. Shaw, Auditor of State. Des Moines, Iowa: State Auditor. Cloth, 6 x 9 in.; pp. 294.

Among the tables of particular interest to municipal engineers is one giving the salaries of department heads in Iowa cities and towns. The report covers all the 105 cities of the state and 719 of the 789 towns listed.

THE NATIONAL FEDERATION OF CONSTRUCTION INDUSTRIES: A Permanent Association of Organizations in the Construction Industries and Professions, Succeeding the Temporary Organization Formed July 15, 1918, under the Auspices of the Chamber of Commerce of the United States of America. Philadelphia, Penn.: The Federation. Paper; 8 x 11 in.; pp. 23.

NEW HAMPSHIRE STATE HIGHWAY DEPARTMENT. Seventh Biennial Report Relative to Highway Improvement. Concord, N. H.: The Department. Paper; 6 x 9 in.; pp. 214; illustrated.

NOTE ON VARIOUS TYPES OF EXTENSOMETERS FOR TESTING BRIDGE GIRDERS—By H. S. Sales. Simla, India: Railway Board of India. Paper; 8 x 13 in.; pp. 16; illustrated.

PEARSON'S PATENT PERMANENT WAY—By J. D. Pearson, B.A., B.E., M. Inst. C. E., Executive Engineer, B., B. & C.I. Ry. Simla, India: Railway Board of India. Paper; 8 x 13 in.; pp. 4; illustrated.

Ties are dispensed with, each rail being riveted or bolted to a flat longitudinal plate 12 in. wide. Gage is maintained by tie bars. A 400-ft. length of this track has been laid.

A PLAN FOR SHOP SAFETY, SANITATION AND HEALTH ORGANIZATION—Issued Under the Direction of the Industrial Commission, John Mitchell, chairman. Albany, N. Y.: New York State Department of Labor. Paper; 6 x 9 in.; pp. 32.

A PORTABLE CUBIC-FOOT STANDARD FOR GAS—By M. H. Stillman, Assistant Physicist, Bureau of Standards. Washington, D. C.: Bureau of Standards. Paper; 7 x 10 in.; pp. 13; illustrated. Free on request.

PROBLEM OF RECONSTRUCTION WITH RESPECT TO URBAN TRANSPORTATION—By Delos F. Wilcox, Ph.D. Reprinted from *National Municipal Review*, January, 1919. Elmhurst, New York City: The Author. Paper; 7 x 10 in.; pp. 15.

THE RELATIVE CORROSION OF CAST-IRON, WROUGHT-IRON AND STEEL PIPE IN HOUSE-DRAINAGE SYSTEMS—By William Paul Gerhard, M. Am. Soc. M. E. New York: The Author, 736 W. 181st St. Paper; 6 x 9 in.; pp. 34; illustrated. 34c., postpaid.

REPORT ON THE BEST PROCESS AND PLANT FOR TREATING RAILWAY SLEEPERS—By C. D. Dove Wilson. Simla, India: Railway Board of India. Paper; 8 x 13 in.; pp. 12; illustrated.

This deals only with English practice in creosoting ties, including the full-cell process, the Ruping empty-cell process and the Boulton boiling process.

RHODE ISLAND STATE BOARD OF PUBLIC ROADS: Seventeenth Annual Report. Providence, R. I. Paper; 6 x 9 in.; pp. 79; illustrated.

SANITATION IN EMERGENCY SHIPYARDS—By W. L. Stevenson, Late Sanitary Engineer, Department of Health and Sanitation, U. S. Shipping Board, Emergency Fleet Corporation. Reprinted from the *Journal* of the Boston Society of Civil Engineers, January, 1919. Address the author, care Pennsylvania State Department of Health, Harrisburg, Penn. Paper; 6 x 9 in.; pp. 18; illustrated.

SPECIAL WATER POWER INVESTIGATION, STATE OF MAINE, 1918. Augusta, Me.: Public Utilities Commission. Paper; 6 x 9 in.; pp. 420; illustrated.

STEAM ENGINE TROUBLES: A Practical Treatise for the Engineer, Telling How to Locate and Remedy Troubles with a Steam Engine—By H. Hamkens, Mechanical Engineer. New York: The Norman W. Henley Publishing Co. Cloth; 5 x 8 in.; pp. 284; illustrated. $2.50.

A revision and extension of a series of articles originally published in *Power*.

STRUCTURAL STEEL FOR SHIPS: Standard Practice Recommended by American Steel Makers as Adopted by the Emergency Fleet Corporation. Revised Nov. 20, 1918. Pittsburgh, Penn.; Carnegie Steel Co. Paper; 5 x 8 in.; pp. 60; illustrated.

THE SUDD REGION OF THE WHITE NILE AND THE HARNESSING OF ITS WATERS—By Sir William Willcocks, K.C.M.G., Late Director General of Reservoir Projects, Cairo, and Director General of Irrigation Projects, Bagdad, and John Wells, Consulting Engineer and Managing Engineer Egyptian Government Research Work. Cairo, Egypt: The Authors. Paper; 7 x 10 in.; pp. 30; illustrated.

WATER CONSERVATION AND IRRIGATION COMMISSION REPORT, NEW SOUTH WALES. 1918. Sydney, Australia: The Commission. Paper; 8 x 13 in.; pp. 29.

WISCONSIN HIGHWAY COMMISSION: Fourth Biennial Report Showing State-Aid Highway Operations, 1916-18. Madison, Wis.: The Commission. Paper; 6 x 9 in.; pp. 358; illustrated.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Return Highway Engineers from France

Sir—You are probably familiar with the literature and advertising which were sent out in the recruiting of the 23rd Engineers. It was represented that this regiment was to be a special road-building regiment made up of experienced construction men—engineers, contractors, superintendents, and all classes of experienced men doing this work.

This regiment probably did a great deal of good work in France, during the year preceding the signing of the armistice. I feel now that it is needed here in the United States more than it is in France. I had a letter from my brother who is in the regiment, written Jan. 27, saying that they were building macadam roads in France on that date, and had been since the armistice was signed.

I do not believe it fair or honest to the members of this regiment to keep them there any longer. Some of the boys who were getting from $150 to $200 per month as foremen and superintendents are working over there with picks and shovels at $33 per month. They were willing and anxious to make this sacrifice during the prosecution of the war, but now that it is over I do not believe that they are willing to do this work, but are anxious to get back here, and I know that we need them. Is there not some way that we can get this regiment returned home?

The Government is urging the building of roads, pavements and buildings, and construction of all kinds, and there is going to be a great amount of this class of work started this month. The 5300 members of the 23rd Engineers, being experienced men, should be here now to take advantage of the opportunities that are opening up. J. K. Shinn.

Independence, Kan.

Injustice to Engineers Returning from Army

Sir—I beg leave to air a grouch against the engineering profession. From time to time you have printed articles regarding the underpaid younger members of the profession, but there is still a lot left unsaid.

Take, for instance, the case of the young engineers with a college education and a few years' experience who have joined the colors. Some entered engineer training camps, others enlisted in engineer regiments, and quite a few, desiring a more personal method of getting at the Hun, entered the line. For the majority of these men, their engineering education proved almost a passport to a commission, and for once at least the value of engineering training was considered at its true worth.

These men, many of whom were employed on construction work long since completed, now stand on the verge of demobilization, and few of them have their former positions open to them. Naturally, most of those who are seeking employment turn their efforts first toward the field of their profession; but what do they find? If there is any demand at all for their services, they are offered positions involving considerable responsibility at the same wage (or less) than a day laborer can demand.

Discouraged, the thought is bound to sink home: "Just what is the incentive to take up their profession where they left off?" Why should a man, well educated and reared in a comfortable home, give up almost everything in life that he has learned to consider worth while, and the best years of his life, to an existence comprised of construction camps and cheap boarding houses, deprived of the society of intellectual equals other than his companions in exile, as many of us have experienced, at less salary than that of a labor foreman in charge of a dozen or so foreign laborers? Why should a man who has spent four years or more at college be unable to demand as much pay as a man who has served an apprenticeship as a plumber, boilermaker, or the like? Take the more intimate side of his life—a man's thoughts usually turn to marriage sooner or later—can an engineer marry a girl of his own station in life, accustomed to the comforts of home and perhaps a few of the luxuries of life, and hope for real happiness with several years of bitter struggle and hand-to-mouth existence ahead? Ought he not be given some slight recompense in the way of salary for the lack of opportunity to establish a home?

The profession blames the public for failure to recognize the engineer's true value; but is the public altogether to blame? Isn't it largely the fault of the engineers themselves? Why should anyone be willing to pay the engineer in charge a fair salary when he himself hires an efficient assistant, often as good as himself, at a mere pittance, and so on down the line? It seems to me that if engineers would quit blaming the public for lack of recognition of their worth, and each and every one would try to get those under him an increase in pay commensurate with their ability, it would soon raise the scale of wages of the whole profession. A. H. Armstrong,

First Lieutenant, United States Marine Corps.

Marine Barracks, Quantico, Va.

Federation of American Engineering Societies Proposed

Sir—The question of consolidation of the engineering profession in America, ordinarily one of importance, has been brought to a head by the war and the reconstruction following it, and there is at the present time much comment upon the activities and policies of the engineering societies which are depended upon to effect the consolidation. The main object is, of course, the public recognition of the engineer, which the engineer feels has not been forthcoming so far, but which he thinks could be materially furthered by the consolidation.

There was a time when the doctors were not recognized any more than the engineers are now, but, thanks

mainly to the effective work of the American Medical Association, that condition is now past, whilst the profession's interests are guarded by a powerful organization, irrespective of whether its members are graduates of a particular university, or of a college of physicians or one of surgeons. Can this be duplicated in the engineering profession?

Influential engineers seriously considering this matter would like to see some kind of a federation of the engineering societies, with some such body as a general engineering board of direction at the head and representative of all. They would like to see a plan put through whereby each qualified engineer would be enrolled as a member of one huge organization, controlled and administered by such a board. Such a development in engineering organizations is a sweeping one, and there is very little sight of it "up the pike" so far.

Who has the scheme which will effectually coördinate all professional engineers, however specialized, and yet exclude all who are deemed insufficiently qualified, and which will not restrict the main activities of the engineering institutions but will embrace them all? Who would like to suggest a democratic Federation of American Engineering Societies?

Who, having suggested such a federation, wants to differentiate the existing organizations so that they may be assigned to their proper places in it? If this much could be worked up as a starter—just to see where we should arrive—and some publicity given to the results, then it might serve to help in many ways. In the first place, new societies might stop long enough in the framing of their charters to consider where they would stand and what little reservation they would fill out in such a federation; this might tend to reduce the number of organizations—a good thing if such reduction means simplification and tends toward better organization and control. In the second place, the older organizations who have, without exception, endeavored to "spread themselves all over the map" might also stop to consider whether "safeguarding the interests of the engineer" can be taken care of by the same organization and the same set of workers in it (for there is always a set of workers) as advance the purely educational side of the profession. In other words—none of which is meant in criticism—the organizations would begin to consider how they could all hold one another's hands without stepping on one another's toes.

All concerned would then probably arrive at an opinion that such bodies as the educational and technical societies—admirable as such—cannot properly take up economic matters concerning the financial position of their members; that such bodies as the local engineering societies should get in on the ground floor in the advancement of public affairs in state or community, and that the federation might try its hand at the national affairs.

The problem is a big one—the biggest the organizations have to face—and if a solution is attempted some organizations will stay up and some will go down. Responsible engineers would say, however, that the attempt is worth while if it only succeeds in inaugurating a legitimate movement which has the goodwill of the majority, and in which all honest organizations can fearlessly participate in the endeavor to create something for the good of all. Such a movement has not yet appeared, although some think they see it in the Engineering Council—which is no criticism of the Engineering Council. The council from the start has, however, represented the few and not the many—there are now five organizations in it out of possibly one or two hundred organizations that are eligible. Its work is being done in good faith; but the large number of societies not yet included, and not provided for in the charter of the council at the outset, would say that the organization, not representing them, is undemocratic. Whether it is or not, they would say it isn't. and so what is the use?

Mr. Flinn, secretary of the council, speaking recently at a general meeting of Canadian engineers, said that for evident reasons it would be impracticable for the Engineering Institute (of Canada) to become a member of the Engineering Council on the same basis as the other five societies, but international coöperation would be desirable, and he would suggest that the Engineering Institute and the Engineering Council should appoint a committee (another committee!) for interchange of good-fellowship and for active coöperation.

Better, then, regard the Engineering Council as what it is—a committee, a joint committee of the four national engineering societies known as the Founder Societies and one or two others, with a program of activities suggested by the participation of engineers in public affairs. It is not, and cannot become, unless its constitution is radically changed, an organization to represent all engineers, which is what we want.

The Engineering Council is apparently the only thing of its kind now existing in this country, and is the only coöperative movement representing a number of the engineering organizations—and, incidentally, it does represent probably 30,000 or 40,000 engineers. But the point is, it does not represent the organized engineering profession. These statements are not in criticism of it, but are merely to show that in this movement there is no sign of such a thing as a Federation of American Engineering Societies would perhaps provide.

WILLIAM E. BULLOCK.
Assistant Secretary, American Society of Mechanical Engineers.

New York.

Giving Credit Where Credit Is Due

Sir—In your issue of Feb. 20, 1919, p. 394, is a letter from C. E. Drayer, secretary of the American Association of Engineers, in which, among other things, he says "the efforts of the American Association to raise the pay of the technical engineer in railroad employ have been successful, much beyond early hopes." This is very encouraging and is fine work, but is the A.A.E. justified in taking all the credit to itself, as is implied by the tone of Mr. Drayer's remarks?

When it was found that the Railroad Administration had overlooked the technical engineer in the matter of increased compensation, both the A.A.E. and the Engineering Council brought the question to the attention of the administration, with the request that justice be done. Now, the Engineering Council represents six national technical organizations, with a combined membership of about 40,000 engineers, and the life history of the oldest of these member societies dates back nearly 70 years. The A.A.E., on the other hand, represents barely 3000 engineers and the years of its

life can be counted on the fingers of one hand. It is a fair question to ask, therefore, which of the two communications carried more weight with the Railroad Administration?

I am thoroughly in sympathy with the aims and work of the A.A.E. It has accomplished wonders in a short time. There seems to be a tendency among its officers and members, however, to claim for the association rather too much of the credit for results obtained, and at the expense of the old founder societies. In fact, the latter are usually ignored or destructively criticized. This attitude I have noticed in the official organ, *The Monad*, and in individual members of my acquaintance. Does this not appear to be a wrong attitude to take? Does it not tend toward bad feeling and disintegration, rather than toward enthusiasm and coöperation in the profession? The latter condition is an avowed aim of the A.A.E., I believe. Again, such an attitude is not warranted in view of the fine results recently achieved by that offspring of the founder societies, namely, the Engineering Council.

Granted that the founder societies needed prodding and awakening, and that they have been asleep to many of their opportunities and responsibilities; granted, too, that the A.A.E. was instrumental in the work of revival, still, the most unsparing critics and the most vehement prodders have been and are, themselves, members of these identical societies. So the A.A.E., after all, is only one of many instruments used in the good work.

Let me mention a few of the resultful and potential activities recently undertaken by the Engineering Council: The splendid service rendered to the Government, the nation, and the profession, during the war, by the American Engineering Service; the good work now being done by the Engineering Societies' Employment Bureau; the recent organizing of the National Service Committee of the Engineering Council at Washington, with its aim of disinterested usefulness to the nation and the profession; the formation by the Am. Soc. C. E. of its Committee on Development, from which great things are expected in the way of solidifying and otherwise helping the profession; the thorough fashion in which the council is now tackling the question of the licensing of engineers; the recent efforts to induce municipal, state and Federal officials to carry forward public works to help relieve the present industrial situation; the letter to President Wilson urging the appointment of engineers to the Commission on Reconstruction (the President's reply is aptly commented on in a letter by M. S. Parker in *Engineering News-Record* of Feb. 20, 1919, p. 395); the attempts to get justice for the railroad technical engineers, as noted above; and, finally, the action taken with regard to the unjust discharge of nearly 400 engineers of the Public Service Commission, New York.

In connection with this last, I am aware that *Engineering News-Record* in an editorial entitled "Will New York Engineers Fail in Their Civic Duty?" waxed indignant because the council at first refrained from action until the case had been presented to it in a "formal communication." A perfectly correct stand to take, was it not? Certainly, as responsible a body as the council cannot take action merely on the evidence of newspaper headlines and street gossip. Anyway, it eventually acted, and results quickly followed.

It must be recognized that the A. A. E. is doing fine work in its attempts to solve the perplexing "reconstruction" problems of the engineering profession. The task is appallingly large and complex. Does it not seem, however, that the objective of all our efforts should be a merger of the existing engineering and technical societies into one main national organization, with two distinct functional divisions; viz., the scientific or technical, and the economic or service? Affiliated district chapters in all parts of the country could take care of local requirements and be used for social and scientific purposes, as are the numerous independent engineers' clubs under the present disorganized conditions.

Some such bold and comprehensive scheme as this, through which action could be unified, is necessary in order to secure the rights of the profession and to achieve its solidarity and the public recognition to which it is entitled.

Charlotte, N. C.

Increase in Prices Due to Labor

Sir—I have read with much interest the article by O. M. Fox, in your Feb. 20 issue, p. 369, on "Material Prices Halt Chicago Building Operations." From a reading of this article, one would naturally blame the manufacturer for the high cost of material, but the writer has overlooked one vital feature which throws the increase in cost not upon the manufacturer, but upon the labor he employs.

In 1913 boiler makers were paid 42½c. and 45c. an hour, and the cost of a fabricated tank, steel, rivets and labor, overhead and margin, was 5c. a pound. Today, with labor 70c. an hour, the labor cost of building this tank is 10c. a pound, no steel, no overhead, no margin. In other words, if steel cost $20 a ton less than the price now being paid, it would make no material difference in the price for which a manufacturer could sell his tanks; and there will be no material reduction in tank prices until labor is willing to do a day's work for the high price they are paid.

We believe that the case cited above is parallel in almost any line of manufacture, such as engines, generators, pumps, and the manufacture and fabrication of steel structures or any other item where labor enters materially into the cost.

F. F. VATER,
President, Power Plant Specialty Company.
Chicago, Ill.

Safety of Workmen Should Receive First Consideration

Sir—The article published in your issue of Feb. 27, 1919, p. 443, with the title "Awning Reduces Lost Time by Hiding Movements of Derrick," has been read by me with much interest.

Without doubt the principle of avoiding the distraction of workmen's attention from their duties is correct and wise, but in applying it in this particular case a more important principle has been lost sight of completely. The carpenters who "stopped work every time the derrick swung its load and stood ready to dodge if it let go" had some justification for their evident fear. The placing of the awning did not remove this

fear, and I question very much whether the placing of the awning effected any saving in the long run.

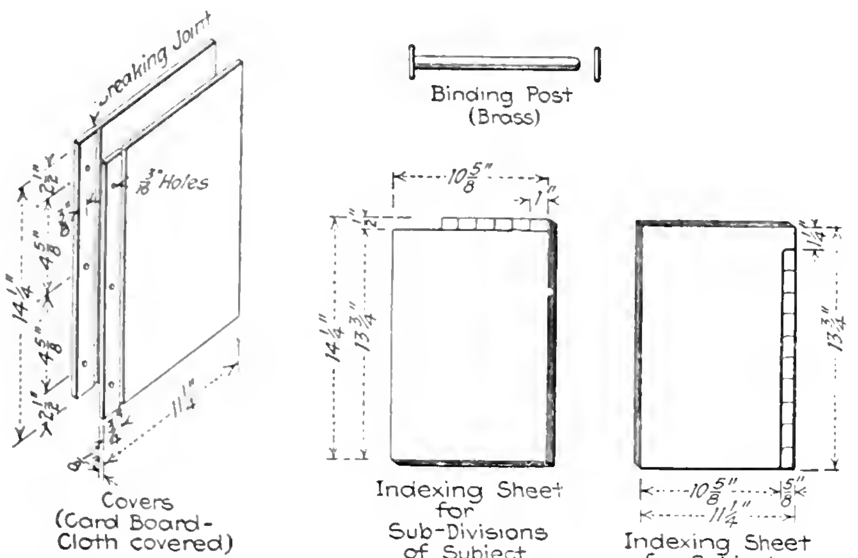
The correct procedure here should have been to avoid even the appearance of danger. The most striking point in the article referred to is that the thought of safety for the workmen does not seem to have entered the mind of the man in charge. This is surprising, considering the attention paid to the matter of safety in these days. J. JAY DUNN.

Ellwood City, Penn.

Engineer's Data File Is Compact and Convenient

Sir—The saying, "He who reads and throws away, may live to rue that very day," once heard is easily remembered, especially when you are looking for that article on a certain subject which you know you had once seen, but cannot recall where or what you did with it. It is the purpose of this article to describe a filing system used by the writer by which it is easy to locate any article deemed of sufficient importance at the time of reading possibly to make it desirable to retain it for later reference.

All articles taken from the various periodicals on subjects of interest, and sometimes the bulletins on various engineering projects, are filed, if not of too bulky a nature, by means of a pair of stiff cardboard covers, brass binding posts and paper separating or indexing sheets, as shown in the sketches. The binding



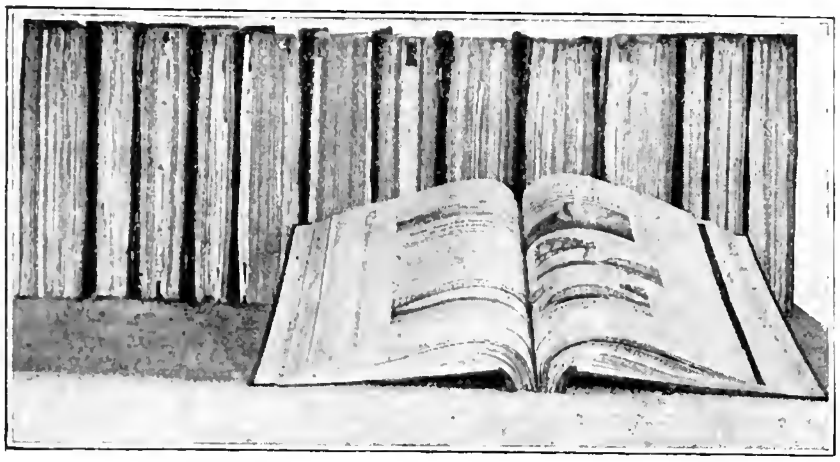
DETAILS OF CARDBOARD COVERS FOR DATA FILE

posts can be purchased from an office outfitter at about 3c. each for the 4-in. size, which is the longest made commercially. The covers can be made up for about 80c. per pair by a book-binding establishment, where the paper for the separating sheets can also be purchased and later cut as required. The size of the covers shown can be used for filing articles taken from any of the periodicals published today.

The most important part of the filing system, as regards convenience, is the separating or indexing sheets, which are bound together with the articles, according to subjects, in alphabetical order. There are subject headings at both the right-hand side and at the top of the volume. The right-hand notations indicate the subject proper, while the top notations indicate the subdivisions of the subject. For example, suppose the subject of boilers is to be referred to, the subdivisions are construction, operation, land types, testing, marine types, etc., the subdivisions being added as the articles are procured.

Articles should be removed from periodicals by pulling out the wire binders with a pair of pliers, instead of cutting the article out with a knife, which very seldom leaves a sufficient margin for filing by this method.

It can readily be seen that a system of this kind can be made very extensive when taken as a whole, yet very simple, due to the fact that all articles that are pos-



ARTICLE FILE AT ACCUMULATED IN TEN YEARS

sessed on a certain subject are all in one place, in convenient form, instead of all over the library, as they would be if put in permanently bound volumes. The photograph shows to what proportions the writer's article file has attained in 10 years.

Generally, articles are not filed as soon as they are received, due to the amount of labor involved in opening up the volumes, but are laid away until a sufficient number have accumulated to make their insertion advisable, the memory being relied upon in the meantime, or entries being made in a card index. All persons who file various data should maintain a card index in which should be listed all books, papers, etc., in the library. The card index, although not absolutely necessary for this type of article file, is nevertheless a good standby.

For the filing of catalogs, pamphlets, books, etc., the writer uses a system of numbers, combined with the first letters of the alphabet, as follows: All books, etc., are filed in four divisions of size, according to height, each size having a certain letter—i.e., those over 10 in. high are designated by the letter A, over 9 in. high and up to 10 in., by the letter B, 8 in. high and up to 9 in. by the letter C, under 8 in. high by the letter D. Filing is then done by the book or pamphlet taking the next consecutive number according to the division to which it belongs, this number being put on the outside so as to be easily seen. A standard sectional book case is used for filing; it contains also a drawer for the card index. A. H. MYERS,

Chief Inspector, Marine Department, Wellman-Seaver-Morgan Company.

Akron, Ohio.

Overhead Charge Between City Departments

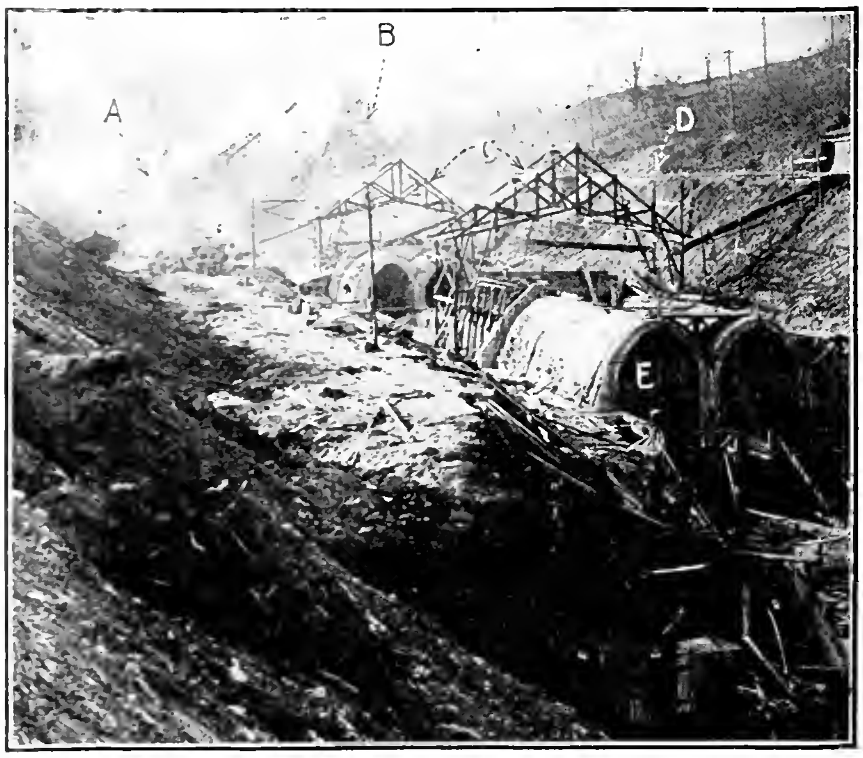
Work done by one department of the City of Detroit for another is paid for at cost plus a percentage for superintendence and overhead expense. The Departments of Public Works and of Parks and Boulevards add 15%, the Public Lighting Commission 10% and the Board of Water Commissioners 20 per cent.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Traveler Carries Concreting Chute and Forms for Conduit

TRAVELERS carry the concreting chutes and handle the outside arch forms, in concreting the outlet conduits for the Germantown dam of the Miami Valley flood-protection works. As the conduit structure at Germantown is at the foot of a very steep hill, it was



TRAVELERS SHIFT CONCRETING CHUTES AND FORMS FROM SECTION COMPLETED TO SECTION BEING BUILT

Other Articles in This Issue of Interest to Contractors:

parts of the structure by means of steel chutes suspended from travelers each consisting of two trusses with the necessary supporting columns and braces. These travelers move on a track consisting of a single line of rail placed along each side of the structure.

The method of operation is as follows: When the outside arch forms are to be moved ahead, the chute, which is suspended from the traveler by block and tackle, is drawn up out of the way. The forms, which are made in three sections for easy handling, are then lifted, one section at a time by means of block and tackle, a sufficient height to pass over the collars of the conduit section already constructed, and are suspended from the traveler. The traveler carrying the three sections of the forms and the chute is then moved ahead to the new position, the forms are lowered into place, and the traveler is then moved to the best position for concreting the section and the chute is lowered to the proper angle for concreting.

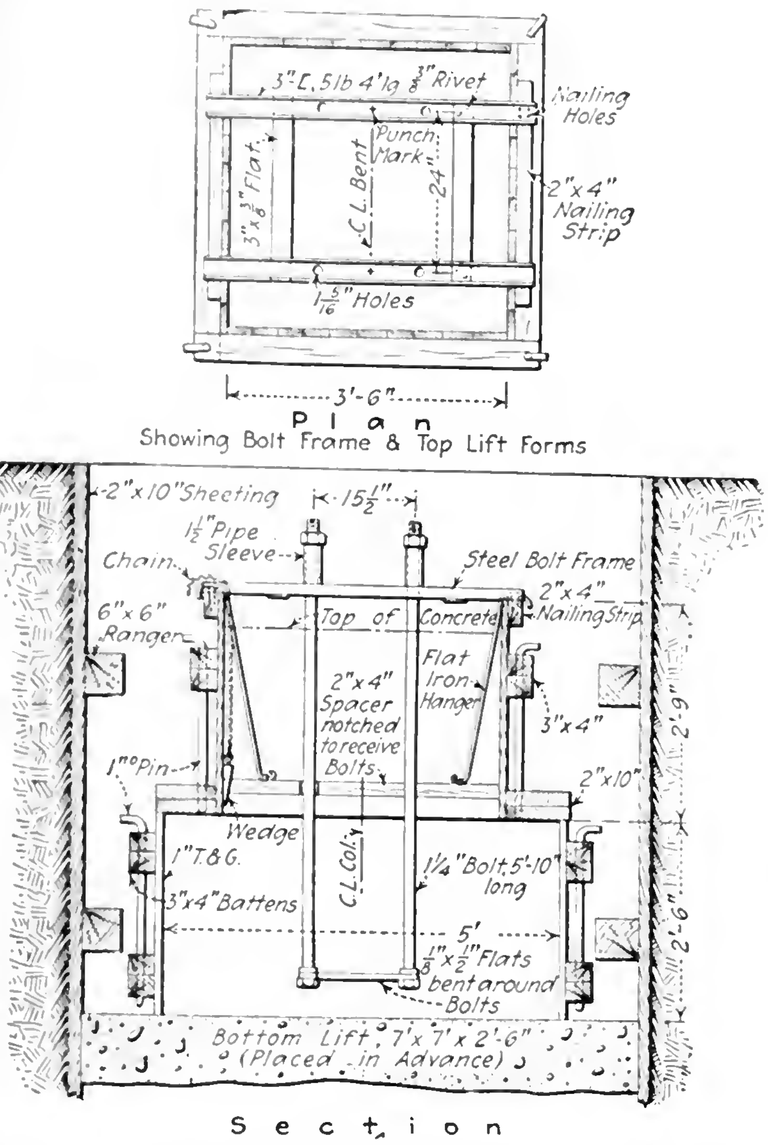
Arthur E. Morgan is chief engineer, Charles H. Paul is assistant chief engineer, and C. H. Locher is construction manager of the Miami Conservancy District.

Anchor Bolts Held in Correct Position While Concreting Footings

BY A. P. ROSCOE
Ozone Park, New York

AS THE result of experience in the construction of about a thousand column foundations for an elevated railroad in New York City, there was developed a special bolt frame and templet for facilitating the work of setting anchor bolts to exact line and grade and holding them in position while concrete was placed for the footings.

The form panels for the two upper lifts were assembled on the completed bottom lift, placed a day or two previously. The 1-in. pins used to fasten the forms were found to be difficult to remove after the concreting was done, and were later replaced by tapered pins



DETAILS OF ANCHOR BOLT TEMPLET FOR FOOTINGS OF COLUMNS

of rectangular section fitting into metal-bushed, circular holes in the battens. The completed form was then carefully braced and wedged against the rangers and sheetings so as to prevent lateral movement and to counteract any tendency of the forms to rise because of the pressure of the concrete.

The bolt frame, or templet, constructed of 3-in. channels and 3 x 3/8-in. flats, was accurately drilled for the four 1 1/4-in. anchor bolts. These frames were light and sturdy and were in good condition when the job was finished. The frame was laid on top of the form and was accurately set by a field party using the center punch marks on the frame; when set they were nailed in place through the nailing holes shown near the ends of the channels. The bolts were set and adjusted to grade by means of the sleeves and nuts shown. This afforded a quick and accurate method of setting the bolts. To hold the anchor bolts in place against the impact of concrete being placed, and to prevent their movement by workmen spading the concrete, they were fastened together at the bottom with 1/2 x 1/2-in. flats bent around the bolts; at the middle point they were stayed by 2 x 4-in. notched spacers wedged against the inside of the forms. By the time the concrete had reached these spacers the bolts were so firmly held by the concrete (and the bolt frame) that the spacing pieces could be removed and concreting completed to the finished grade. It was found to be worth while to attach a chain to the wedge and iron hangers to the spacing pieces, as shown, so as to permit their ready withdrawal, rather than to waste the time of the entire gang while a laborer fished out the wedges, etc., which operation, owing to the confined space, caused exasperating delays in the beginning.

Hoisting Engines Used to Help Trucks on Seventeen Per Cent. Grade

HAULING of excavated material from the deep cut which is being widened to give railway connection to the South Brooklyn Army supply base was accomplished by means of motor trucks helped by auxiliary hoisting engines. The grade was upward of 17 per cent., and was planked, as shown in the accompanying illustration.

That the trucks might not be delayed, two 9 x 12 hoisting engines were placed at the top of the grade, one on each side. While a truck is coming up on one side, another is going down on the other. Letting the trucks down by cable was not absolutely necessary, but was considered safe and acted as a means for taking the cable down to bring up the next load.

To center the cables on the roadway a deadman consisting of a large steel I-beam, securely embedded in the ground, was placed in the center and just beyond the brow of the hill. To this two large pulleys were attached, and the lines from the engines passed through these and thence down the grade. By this means trucks carrying about four cubic yards of material were easily operated.

This work is under the supervision of the Construction Division of the Army. Brig. Gen. R. C. Marshall, Jr., is chief of the Construction Division, Lieut. Col. H. S. Crocker is constructing quartermaster, and Maj. J. W. Cerny, Quartermaster Corps, National Army, assisted by Capt. L. A. Sumner, is directly in charge of the work described. The general contractor is the Turner Construction Co. of New York City, of which A. C. Tozzer is executive manager, and the subcontractor for the hauling is Rodgers & Haggerty, of New York.

NEWS OF THE WEEK

New York, March 20, 1919

Passaic Valley Sewage Disposal Suit Reopened

A reopening of the suit brought by the city of New York against the Passaic Valley Sewerage Commission (nominally the State of New York against the State of New Jersey) has been ordered by the United States Supreme Court. The suit was originally brought in October, 1908, to prevent the alleged pollution of the waters of New York Bay by the treated sewage of Newark and other communities included in the Passaic Valley Sewerage District. Testimony was taken from June, 1911, to June, 1913, but the case was not argued until late in 1918.

The court holds that supplementary evidence is needed. It permits the defendants to take the testimony of not more than three "sanitary or engineering experts" on (1) "any practicable modification of the proposed system of sewage treatment" that would lessen the alleged pollution, and (2) on "any practicable plan of sewage disposal or treatment" applicable to New York City sewage that would lessen the pollution of the harbor. In addition (3) both parties are authorized to take evidence on the degree of pollution of the harbor. The evidence in behalf of the defendants must be in by Aug. 15, 1919. Between then and Sept. 15 the defendants may, if desired, recall in rebuttal the experts who have testified under (1) and (2) and may also offer rebuttal evidence under (3).

After the new evidence is all in, a date for further argument will be set. The evidence will be taken by James D. Maher, clerk of the United States Supreme Court, sitting as a commissioner in New York and Newark. Mr. Maher took the earlier evidence in this case.

Engineering Regiment Cited

For conspicuous gallantry in action on the last night of the war, the Second Engineers were cited in the orders of Maj. Gen. J. A. Lejeune, commanding the Second Division. The citation reads as follows:

1. On the night of Nov. 10, heroic deeds were done by heroic men. In the face of heavy artillery and withering machine-gun fire, the Second Engineers threw two foot-bridges across the Meuse, and the first and second battalions of the Fifth Marines crossed resolutely and unflinchingly to the east bank and carried out their mission.

2. In the last battle of the war, as in all others in which this division has participated, it enforced its will on the enemy.

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Professional and Special Section, United States Employment Service:

16 East 42nd St., New York.
63 E. Adams St., Chicago.
1518 Walnut St., Philadelphia.
16 Tremont St., Boston.

N.B. Official information has been received that all offices of the Professional and Special Section of the United States Employment Service will close Mar. 22, unless they can be temporarily continued by local interests. This action is made necessary by the failure of Congress to appropriate funds.

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

American Association of Engineers, F. H. Myers, manager, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Engineers' Service Bureau, maintained by the Joint Council of Engineering Societies of San Francisco, care of B. P. Legare, Engineers' Club, 57 Post St., San Francisco. Only applications by mail or wire will be considered.

Joint Influenza Committee

The Surgeon Generals of the Army, the Navy and the United States Public Health Service, and the Director of the Census, have created a joint committee to study and compare the influenza data of the various Government departments. The members are: Dr. William H. Davis, chairman, and C. S. Sloane, representing the Bureau of the Census; Dr. Wade H. Frost and Edgar Sydenstricker, of the Public Health Service; Col. D. C. Howard, Col. F. F. Russell and Lieut. Col. A. G. Love, U. S. A.; Lieut. Commander J. R. Phelps and Surgeon Carroll Fox, U. S. Navy.

United States Employment Service Greatly Curtailed

Failure of Congress to pass the Urgent Deficiency Bill in the last days of the session has made it necessary for Secretary Wilson of the Department of Labor to curtail by 80% the United States Employment Service to returning soldiers. It was hoped that this deficiency might be overcome by drawing on President Wilson's war emergency fund, but this has been exhausted.

It is proposed to save a skeleton by retaining a 20% organization, around which various other Government agencies, welfare organizations, etc., will be centralized to carry on the work. In doing this, the 56 regular branch offices which remain of the 750 which had been established will be located in the strategic industrial centers.

Unemployment, as indicated by reports of cities to the Department of Labor, is increasing from week to week, and this curtailment of the Employment Service is considered unfortunate. It is hoped that local communities will continue the Government work.

Training Camps Association Takes Over Employment Work

Left without funds, the Professional and Special Section of the United States Employment Service in Chicago has turned over to the Military Training Camps Association a restricted portion of its work. The association proposes to handle applications from men returning from service only. This means much to engineers, for there are approximately 500 applicants in the Federal files. The Chicago office under the new organization, with W. R. Robinson as its head, has just begun to function, having placed 26 men, exclusive of teachers, during the week which ended Mar. 15. D. A. Tomlinson, who became the head of the office Mar. 15, Mr. Robinson having gone with the Curtis Publishing Co., will remain with the service only until the shift has been effected.

The Military Training Camps Association is located at 220 So. State St., and has a strong national organization maintained by membership fees and contributions. It has the military backing of General Wood, who was recently transferred to Chicago in command of the Central Department of the Army, and has interested himself in the employment situation. For the purpose of continuity of service the association has placed the nucleus of the Federal bureau's staff on its payroll.

Government Surplus Lumber For Sale

The Director of Sales of the War Department has executed a contract with J. L. Phillips and John Stephens, of Jacksonville, Fla., the representatives of the lumber producers, for all of the surplus lumber in the War Department on projects where there is any considerable quantity to be disposed of.

Messrs. Phillips and Stephens can be reached at 708 13th St., N. W., Washington, D. C., and will receive any offers on lumber which they have for sale for the War Department. They have purchased this lumber and agree to resell it at the market price for the various species and grades of lumber, paying to the War Department the amount received for this lumber, less the actual expense of selling; and, in addition, they agree to clean up the entire surplus lumber within the coming six months.

The quantity covered under the contract with the department was 188,000,000 ft., and additional quantities in sight from the department and the Housing Corporation made the amount over 200,000,000 ft. The department has now withdrawn from the contract all the lumber at all the camps and from some storage points, the amount aggregating approximately 160,000,000 ft. This lumber will not be sold. This will leave only between 30,000,000 ft. and 40,000,000 ft. located at widely scattered points and of a variety of sizes, species and grades.

Water-Main Extension Problems Feature of Meeting

Following a short lantern-slide talk on the recent break in a 1200-hp. turbine at the Wachuset dam, by William E. Foss, chief engineer of the Metropolitan Water-Works (as mentioned in *Engineering News-Record* of Feb. 20, 1919, p. 403) the New England Water-Works Association at Boston devoted the rest of its time, after the monthly luncheon on Mar. 12, to a discussion of meeting the cost of water-main extensions. The first speaker, M. N. Baker, of the editorial staff of *Engineering News-Record,* suggested wider use of the assessment-for-benefits plan, especially in view of the fact that the war and prohibition have joined hands in making more difficult than ever the problem of financing municipal improvements.

Coupled with Mr. Baker on the program was C. M. Saville, chief engineer and manager of the Hartford waterworks. In Hartford, property owners now guarantee a yearly revenue of 10% for 10 years on the cost of a main large enough to supply the street. C. E. Davis stated that in Philadelphia property is assessed $1 a front foot for main extensions. The assessment is a lien on the property. With a prospect of diminishing revenues due to prohibition, it has been proposed that there be levied an assessment for the high-pressure fire system, based on the cubic space in the buildings projected.

A. R. Hathaway of Springfield, Mass., said that in his city property owners may divide the charge for a water main extension among themselves as they see fit. Leonard Metcalf of Boston approved the general plan of assessment for benefit, which he thought is more common than generally supposed. In the West, where lots are large and much of the city area is sparsely settled, there is a strong argument for the plan. F. P. Stearns thought that the assessment plan would discourage applications for extensions.

Alaskan Railroad Work Curtailed

Owing to the failure of Congress to provide necessary funds, it is probable that work on the Alaskan Government railroads will have to be materially curtailed. The construction work under way even may be reduced, and certainly no new work will be undertaken unless an extra session of Congress should make the needed funds available.

Illinois Has Waterway Project

A new plan for a waterway to form a link in the Lakes and Gulf waterway by connecting the Chicago Drainage Canal with the Illinois River at La Salle, Ill., is contained in a bill submitted to the state legislature. It has the backing of Governor Lowden, and was prepared by the State Department of Public Works and Buildings. The channel will have a bottom width of 150 ft., with a water depth of 8 ft. in earth sections, 10 ft. in rock and 14 ft. over lock sills. Locks 110 x 600 ft. long are provided, enabling fleets with 5000 to 7000 tons of freight to be accommodated. The cost is estimated to come within the bond issue of $20,000,000 which has already been authorized by public vote. When the bill is passed the project will be submitted to the War Department, and it is hoped that approval will be given in time to permit of starting work this season.

Outlook for Highway Improvements in California

Several county bond issues are to be voted on, and several others are proposed, in California, according to reports. A $40,000,000 bond issue is also being contemplated for the state at large.

Among the counties, Fresno will vote on $4,600,000 on May 6, while Sonoma will vote on $1,600,000 on May 27. Marin County has requested a Government engineer to prepare highway plans, and five northern counties have requested an engineer to lay out an intercounty system for them.

In addressing the State Road Supervisors' Association, Governor Stephens stated that the state-wide bond issue mentioned above is about to be proposed, and requested their united support. This was given in the form of a resolution which was passed by a large majority.

Ontario Good Roads Association Meets in Toronto

Great interest in the subject of good roads was shown at the 18th annual convention of the Ontario Good Roads Association, held in Toronto, Mar. 5-7, when 300 delegates met to discuss the road problems of the province. Public work to tide over the labor shortage of the reconstruction period, together with changes in the laws affecting labor upon the roads, was the principal topic of the speakers.

What is known as "statute labor," or working out the road tax, received the greatest amount of discussion at the convention. It was the sense of the meeting, as expressed in a resolution carried by a fair majority, that this form of road administration should be discontinued, and that the road construction of counties should be put under a competent surveyor.

A great increase in motor traffic, as evidenced by the advance in receipts from licenses from $950,000 in 1917 to $1,200,000 in 1918, makes it necessary, according to the Hon. George S. Henry, minister of agriculture, to put the township roads of the present system into such condition that they can be used all the year round.

The following officers were elected for the ensuing year:

President, K. W. McKay, St. Thomas; first vice-president, J. J. Parsons; second vice-president, W. H. Pugsley, Richmond Hill; third vice-president, Capt. Lucius E. Allen, Belleville; secretary-treasurer, the Hon. George S. Henry, member of the provincial Parliament; assistant secretary-treasurer, Maj. T. L. Kennedy.

Federal Highway Council To Hold First Meeting in Chicago

The first meeting of the newly organized Federal Highway Council, described in *Engineering News-Record* of Feb. 6, 1919, p. 303, will be held at the Congress Hotel, Chicago, Apr. 7-8. The meeting will open with an informal "get-together" dinner on Monday evening, Apr. 7.

Representatives of 38 state highway departments, together with 190 prominent men representing civic organizations throughout the entire country, have accepted membership in the council and are expected to be in attendance. Indorsement by many organizations of the national highway policy and plan outlined at the Chicago Highway Congress by E. J. Mehren, editor of *Engineering News-Record,* indicates the interest in highway work throughout the country and suggests a wide field of action for the Federal Highway Council.

Road-Bond Issue Submitted to Vote by Legislature

Another state was added to those which have submitted large highway bond issues to a vote of the people, when the Governor of Washington signed a bill passed by the legislature

providing for a referendum on an issue of $30,000,000. The measure will be voted upon at the general election in 1920 and, if it is carried, the funds will be used to build hard-surfaced roads throughout the state. A bill providing for county superintendents of highways reporting directly to the State Highway Commission, reported in *Engineering News-Record* of Feb. 13, 1919, p. 351, was defeated.

Interior Department Obtains High Explosives for Road Work

High explosives worth $10,000,000 and consisting largely of TNT have been turned over by the War Department to the Department of the Interior for reconstruction purposes. It is reported that Secretary Lane, of the Interior Department, plans to use much of this material for blasting on road-building projects.

Federal-Aid Highway Appropriation Goes Through

Federal aid for highways received a large addition when the Postoffice appropriation bill went through the Senate carrying $200,000,000 for this purpose. The bill, which was noted in *Engineering News-Record* of Jan. 30, 1919, p. 251, now awaits the signature of the President.

The provisions of the bill greatly enlarge the scope of the term "rural post road," to cover roads that either are used or can be used for transportation of the mails. It also increases the maximum payments which the Federal Government can make per mile from the previous amount, $10,000, to $20,000. This will allow the building in coöperation with the states of roads costing $40,000 per mile.

Canada Takes Over Grand Trunk Pacific

The Grand Trunk Pacific Ry. has been taken over by the Canadian government, which assumed control at midnight Mar. 9. The Hon. J. D. Reid, minister of railways, was appointed receiver. This action was caused by an official notification received by Sir Thomas White, acting premier, from the vice president of the railway, that, in view of the fact that the increased rates have not been sufficient to meet the increased operating expenses, it would not be possible for the company, owing to lack of funds, to continue its operations beyond Mar. 10. The War Measures Act was held to provide adequate authority for immediate action by the Government to prevent interruptions in the operation and management of the system.

W. P. Hinton, the general manager, has agreed to conform to the requirements of the Government and to facilitate the carrying out of the powers and duties required by the minister of railways as receiver. The acquisition of the road adds 1964 miles of main road and about 1000 miles of branch line to the Government system.

Oklahoma Society Considers Paving Brick and Concrete Tanks

Influenza compelled the postponement of the annual meeting of the Oklahoma Society of Engineers in October last, and the deferred meeting was held in Oklahoma City, Mar. 6. Trouble with reinforced-concrete tanks was described by R. E. Brownell, district engineer of the Portland Cement Association, and the discussion indicated a general opinion that tanks 12 to 30 ft. high, made with 1:2:4 concrete, should be waterproof if properly built. Mr. Brownell pointed out that to produce strong concrete the water must be measured as carefully as the other materials.

Officers of the society for the short term of 1919 were elected as follows: President, T. P. Clonts, county engineer, Muskogee; vice-presidents, Col. Frank B. King, R. E. Brownell and D. W. Patton; secretary, H. V. Hinckley, Omaha City, Okla.

Civil Service Examinations

For United States Civil Service examinations listed below, apply to United States Civil Service Commission, Washington, D. C., or to any local office of commission, for form 1312.

United States.—Superintendents of road construction, Bureau of Public Roads, Department of Agriculture, Mar. 25: Class A (candidates with four years' responsible charge of construction) $150 to $175 per month: Class B (six years' responsible charge) $185 to $225; Class C (eight years' responsible charge) $230 to $250 a month. File applications before Mar. 25.

United States.—Assistant examiner, Patent Office, Washington, Mar. 26-28, and May 21-23 and July 23-25. Pay, $1500 per year. File applications in time to arrange for examinations at place selected by applicant.

United States.—Chief physicist, qualified in aëronautics, National Advisory Committee for Aëronautics, Langley Field, Hampton, Va., Mar. 25, $3000 per year. Also physicist, $2100 per year. File applications before Mar. 25.

United States.—Senior highway bridge engineers, Apr. 1, Bureau of Public Roads, Department of Agriculture, Washington, D. C. Grade 1 (examination percentage above 70) $2400 to $2700 per year; Grade 2 (percentage above 80) $2800 to $3000 per year; Grade 3 (percentage above 90) $3100 to $3400 per year. File application before Apr. 1.

United States.—Engineer-draftsman, Apr. 22, $1500 to $1800 per year. File application before Apr. 22.

United States.—Transitman, $100 to $125 per month, and surveyor, $125 to $200 per month, Mar. 26-27 and Apr. 23-24. File applications in time to arrange for examination at place selected by applicant.

United States.—Aëronautical engineering draftsman, National Advisory Committee for Aëronautics, Apr. 1, $1500 per year. File applications before Apr. 1.

Engineering Societies

Calendar

Annual Meetings

NATIONAL FIRE PROTECTION ASSOCIATION; 87 Milk St., Boston, Mass.; May 6-8, Ottawa, Can.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

The Niagara Peninsula Branch of the Engineering Institute of Canada was formed at a meeting at Niagara Falls, Ont., Mar. 11, attended by members of the Engineering Institute of Canada and other engineers resident in the Niagara district. Frazer S. Keith, general secretary, explained the scope and functions of the Engineering Institute to a large gathering of representatives from St. Catharines, Thorold and Niagara Falls. Visiting engineers were present from New York City, Philadelphia and from the Hamilton branch. The following officers were elected: Chairman, A. C. D. Blanchard, Niagara Falls, Ont.; vice-chairman, W. P. Near, St. Catharines, Ont., and secretary-treasurer, R. P. Johnson, Niagara Falls, Ont.

The Society of Polish Engineers and Business Men in America, with headquarters in the Engineering Societies' Building, 29 West 39th St., New York City, has been organized to work in conjunction with the Commercial and Industrial Bureau of the Polish National Department, 33 West 42nd St. The organization is headed by Ralph Modjeski, as honorary president. Steven de Csesznak, publisher of *Export American Industries*, is president.

The Iowa Section of the American Water-Works Association will hold its fourth annual meeting at the State University of Iowa, Iowa City, Apr. 16-17. Preliminary plans for the meeting indicate that a prominent place will be given to the reconstruction and extension problems of water-works under existing abnormal conditions.

The Engineers' Society of St. Paul held its regular monthly meeting Mar. 10. A motion picture, "From Ore to Finish 'National' Pipe," produced by the National Tube Co. of Chicago, was shown. The society was recently represented by a committee which addressed the appropriations committee of the state legislature on the neces-

sity of having an appropriation to continue the topographic mapping of the state, and hydrographic surveys, in conjunction with the United States Geological Survey. The committee representing the society was composed of E. V. Willard, state drainage engineer; G. O. House, general manager of the Northern States Power Co.; L. P. Wolff, consulting engineer, St. Paul, and E. C. Dugan, of the United States Engineer's office, St. Paul.

The Bankhead National Highway Association will hold its third annual meeting at Mineral Wells, Tex., Apr. 18-19. Delegates from all the states along the line of the Bankhead Highway, from Virginia to California, are expected to attend. The United States Good Roads Association, of which Senator Bankhead is president, will also meet during the same week at Mineral Wells, beginning on Apr. 14. There will be an exhibit of machinery and materials. J. A. Roundtree, Birmingham, Ala., is secretary of the Bankhead National Highway Association.

The American Association of Engineers will hold a meeting in Chicago, Mar. 21, at which W. E. Skinner will speak on the proposed $10,000,000 soldiers' memorial building.

The Engineers' Club of Philadelphia will be addressed by Joseph A. Steinmetz on "News from the Peace Zone," at the weekly luncheon Mar. 25.

The Technology Club of Syracuse, N. Y., was addressed Mar. 17 by Henry C. Allen, city engineer, on "The Water Supply of Syracuse." On Mar. 24 C. E. Drayer, secretary of the American Association of Engineers, will speak on the work of the association.

The Quincy, Ill., Engineers' Society elected the following officers at the recent annual meeting: President, W. F. Gerdes; vice-president, W. C. Dowd; secretary-treasurer, Dwight P. Child. A paper on street paving, by Webster P. Bushnell, was presented.

The Montreal Branch of the Engineering Institute of Canada will be addressed Mar. 27 by R. de L. French, who will read a paper entitled "Some Notes on the Design and Construction of Reinforced-Concrete Covered Reservoirs."

The Southern California Association of Members of the American Society of Civil Engineers has planned a series of discussions on flood control in southern California. The regular meetings of the association have been changed from bimonthly to monthly. After the first topic has been covered, other "local engineering problems of vital consequence to the community" will be considered along professional lines. At the first meeting, which was held on Mar. 12, there was an introduction of the flood-control subject by George G. Anderson, a historical sketch by F. H. Olmsted, and a talk on the physiography involved, by A. L. Sonderegger.

The New England Water-Works Association will hold its next annual meeting in Albany. The time will probably be the second week in September.

The Duluth Engineers' Club held its monthly meeting Mar. 15, at which the committee on local transit reported on Duluth street-railway conditions with respect to factors attending impairment of the service last winter.

The Engineers' Club of Seattle, at a recent meeting, was addressed by Maj. William F. Allison, who spoke on "The Work of the Sanitary Engineers with the American Army in France."

The Engineers' Club of Minneapolis was addressed Mar. 17 by Professor Comstock of the Minnesota State University of Mines, who spoke on "The Mining Industry of Minnesota."

Personal Notes

COL. F. A. MOLITOR, Twenty-Second Engineers, has been discharged from the Army and has returned to New York to resume his consulting practice. The Twenty-Second Engineers, which Colonel Molitor commanded, was assigned to the construction of light railways. In November Colonel Molitor was detailed from his regiment and placed in charge of engineer supplies.

ROY MULLINS, division highway engineer of New Jersey at Trenton, has been appointed division engineer in charge of the northern division, with headquarters at Newark, succeeding E. M. Vail, who has been put in charge of the new department of maintenance, as noted elsewhere.

MAJ. I. S. OSBORN, Quartermaster Corps, U. S. A., has been discharged from the service and has returned to engineering practice with the Allen-Osborn Co., engineers and architects, of Cleveland, Ohio. At the request of Herbert C. Hoover, he organized the Garbage Utilization Division, United States Food Administration, later resigning to enter the Army to organize the Reclamation Division in the Quartermaster Corps, of which he was chief during the first part of 1918. During the latter part of the year he was assigned to special duties and inspection work in connection with the Salvage Division, Office of the Director of Purchase, Storage and Traffic.

HENRY E. ELROD, DAVID DRENNAN and FRANK S. TAYLOR, formerly of the engineer firm of Lyndon, Taylor & Perrilliat, New York City and New Orleans, have become associated under the firm name of the Henry Exall Elrod Co., Dallas, Tex., consulting engineers, successors to Henry Exall Elrod. The new organization will continue to specialize in municipal work, utility valuation and regulation, and highway engineering.

H. A. SCHAFFER, previously of the firm of Harrison & Schaffer, consulting engineers and chemists, Easton, Penn., has joined the staff of the Portland Cement Association as chemical engineer to conduct conservation studies. From October, 1918, he was acting as advisory chemist and assistant to the Director of Building Materials, War Industries Board, Washington.

MAJ. W. A. WELCH, Air Service Aircraft Production, U. S. A., division engineer, Spruce Production Division, and chief engineer, Spruce Production Corporation, has been discharged from the service and has returned to his former position as chief engineer of the Palisades Interstate Park Commission.

MILO S. KETCHUM, assistant director of the United States Government explosives plant, who since February, 1918, has been in charge of the construction of the smokeless-powder plant at Nitro, W. Va., has returned to the University of Colorado to resume his duties as dean of the College of Engineering and professor of civil engineering.

CAPT. A. U. WETHERBEE, Chemical Warfare Division, U. S. A., who was formerly chief engineer and assistant works manager of the Niagara Alkali Co., recently received his discharge from the service and has become chief mechanical engineer, Powdered Coal Engineering & Equipment Co., Chicago.

LIEUT. C. F. URBUTT, Construction Division, U. S. A., has received his discharge from the service and has been appointed district engineer, Chicago, Milwaukee & St. Paul R.R., with office in Chicago, succeeding W. L. Webb, assigned to special work in connection with the Chicago Union Station, as noted elsewhere.

ARTHUR H. BLANCHARD, consulting highway engineer, New York City, has been appointed chief of the Bureau of Public Works, Department of Citizenship, under the Army Overseas Educational Commission of the Y. M. C. A. General Pershing has requested the Y. M. C. A., through its commission, to take charge of the development of instruction and courses for all educational work of the Army overseas. The staff of the Bureau of

Public Works and Army instructors, in 500 post schools throughout France, will give lectures and courses relative to waterways, railways, highways, bridges, water-supply, sewerage, waste disposal, public utilities, and irrigation.

LIEUT. WILLIAM H. HOBBS, 332nd Field Artillery, American Expeditionary Forces, has received his discharge from the Army and resumed his work as assistant engineer, Louisiana Division, Missouri Pacific R.R., with headquarters at Monroe, La.

H. W. SKIDMORE, construction engineer, Department of Public Works, Village of Oak Park, Ill., on Apr. 1 will become associated with Lester Kirschbraun, consulting and testing engineer of Chicago, and will become associate director of the Chicago Paving Laboratory, devoting practically all of his time to the paving field.

LIEUT. G. D. SHANNON, Ordnance Department, U. S. A., formerly highway division engineer, Vermilion County, Illinois, has received his discharge from the service and has become highway engineer of the Joplin, Mo., road district, in charge of construction.

LIEUT. WILLIAM F. BROCK, Engineers, U. S. A., stationed at Camp A. A. Humphreys, Virginia, has received his discharge from the service and has returned to his work with the Interstate Commerce Commission, Division of Valuation. He is at present located at Newbery, Fla.

L. P. SCOTT, assistant engineer, Road Department, Office of the Constructing Quartermaster, Camp Henry Knox, Kentucky, since his discharge from the service, has become constructing engineer on highway work for Sedgwick County, Kansas, with headquarters at Wichita.

U. S. MARSHALL, senior highway engineer, Bureau of Public Roads, who has just completed the paving work at Camp Lewis, Washington, has been transferred to Missoula, Mont., in charge of Federal road work in the state, succeeding J. S. Bright, transferred to District No. 3, Denver, as noted elsewhere in this issue.

E. M. VAIL, division state highway engineer in charge of the northern division, New Jersey, with headquarters in Newark, has been promoted to head the new department of maintenance.

COL. WILLIAM D. WRIGHTSON, chief of the Sanitary Corps, U. S. A., has received his discharge from the service and has resumed his connection with the International Health Board of the Rockefeller Foundation as sanitary engineer and member of the yellow fever commission. He will sail this month for South America, in company with Maj. Gen. William C. Gorgas, chairman of the commission, and Brig. Gen. Theodore C. Lyster, member of the commission, to investigate yellow fever conditions in Central and South America.

COMFORT AVERY ADAMS, previously professor of electrical engineering and Lawrence professor of engineering, Harvard University and Massachusetts Institute of Technology, has been appointed dean of the School of Engineering at Harvard.

CAPT. ALLAN V. ELSTON, 314th Engineers, American Expeditionary Forces, has received his discharge from the service and has resumed private practice in the firm of Wood, Elston & Witten, consulting engineers, Tulsa, Okla.

JOHN FLYNN, JR., who recently completed his work as project and supervising engineer, United States Housing Corporation project, Watervliet, N. Y., has been appointed village engineer of Green Island, N. Y., for the ensuing year.

LIEUT. FRANK W. VARDEN, U. S. A., formerly with the Koppers Co., has been discharged from the service and has entered the technical department of the Barber Asphalt Paving Company.

O. H. FRICK, field engineer on valuation work, Chicago, Milwaukee & St. Paul R.R., has been appointed district engineer, middle district, with headquarters in Milwaukee.

G. H. BISHOP, previously with the United States Public Health Service, Montgomery, Ala., has become chief engineer for the Cement Products Co., manufacturer of "Sanisept" portable sewage-disposal systems.

J. S. BRIGHT, engineer in charge of the branch office of the Bureau of Public Roads at Missoula, Mont., has been appointed engineer in charge of District No. 3, with headquarters in Denver.

W. F. CRAWFORD and R. N. WHITTESEY have become associated under the firm name of Crawford & Whittesey, civil and consulting engineers, Sapulpa, Okla.

MAJ. JAY A. ROSSITER, formerly track elevation engineer, Chicago, and CAPT. C. C. SANER, assistant engineer, on the city engineer's staff, Chicago, announce the opening of a sales engineer's office in the Union National Bank Building, Houston, Tex. Major Rossiter and Captain Saner were connected with the 108th Engineers, formerly a Chicago National Guard regiment. The new firm, Rossiter & Saner, represent the following manufacturers: Page-Burton Boiler Co.; F. C. Austin; Yeomans Bros.; Williams-Wendt Co.; Austin Manufacturing Co.; Baylis Sanitary Supply Co.; Chicago Waste Co.; American Steam Conveyor Corporation; Boland Construction Co.; Municipal Supply Co.; Universal Engineering Co., and Typhoon Ventilating System.

W. L. WEBB, district engineer, Chicago, Milwaukee & St. Paul R.R., with headquarters in Chicago, has been assigned to special work in connection with the Chicago Union Station.

JOSEPH W. HUNTER, formerly state highway commissioner and since 1911 first deputy highway commissioner of the Pennsylvania State Highway Department, has been appointed township commissioner of the department.

LIEUT. ALLEN F. SHERZER, 301st Feld Artillery, American Expeditionary Forces, has resumed his work with the Kingsford Foundry & Machine Works, Oswego, N. Y., having received his discharge from the service.

ROBERT C. BERLIN,, PERRY W. SWERN, and FRANK A. RANDALL have become associated as the firm of Berlin, Swern & Randall, architects and engineers, 19 So. La Salle St., Chicago.

GEORGE H. BILES, second deputy highway commissioner of Pennsylvania for the past three years has been appointed assistant highway commissioner.

R. A. BOOTH has resigned as state highway commissioner of Oregon.

OBITUARY

LYNDEN B. SCHOEMAKER, for the past nine years engineer of distribution, Department of Water Supply, Brooklyn, N. Y., died in that city Mar. 10, at the age of 34. He was graduated from Princeton in 1906 and served as an instructor during the following year, afterward entering the service of New York City.

THOMAS FLETCHER OAKES, former president of the Northern Pacific R.R., died in Seattle Mar. 14 at the age of 76. He directed the construction of the road from Spokane to Seattle. In 1863 he entered the service of the Kansas Pacific Ry., from which he resigned as vice-president in 1879 to become general superintendent of the Kansas City, Fort Scott & Gulf R.R. He later served as vice-president and general manager of the Oregon Ry. & Navigation Co. In 1881 he became vice-president of the Northern Pacific, and served as president from 1888 to 1893, when he was appointed receiver for two years.

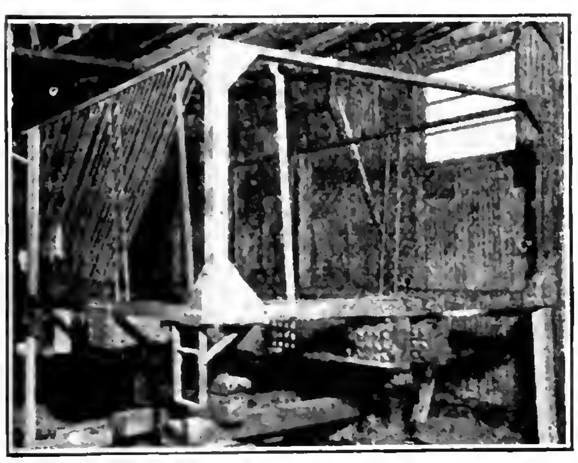
Concrete Freight Car Designed to Relieve Steel Shortage

A reinforced-concrete gondola car, having concrete sides, ends and floor with a steel skeleton body frame, and mounted on a steel underframe, was on exhibition in Chicago recently and represents a new development in the use of concrete. It was designed during the war as a means of relieving the shortage of steel and the demand for cars, but plans are being made for

FREIGHT CAR HAS CONCRETE SIDES AND FLOOR ON STEEL FRAME

manufacturing various types of concrete cars on a commercial scale.

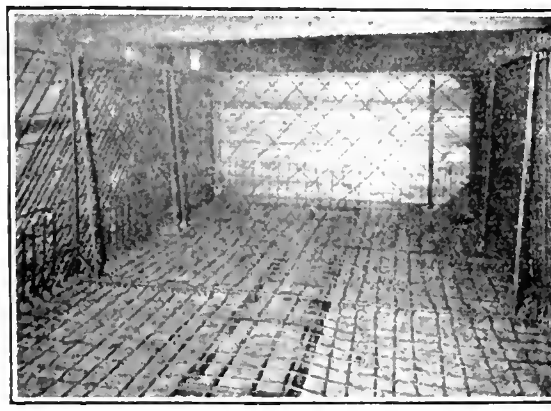
The car has a body 41 ft. long, 9 ft. 8 in. wide and 4 ft. 8 in. deep. It is designed for 50 tons load capacity plus 10% for overload. Unit stress was taken at 16,000 lb. in steel and 1000 lb.



STEEL FRAME AND REINFORCEMENT OF CONCRETE FREIGHT CAR

in concrete. Impact was computed at 25%. As the thickness of the concrete is only 2½ in., it was decided to use the cement gun for making the sides and floor, the cross-bearers being poured in the usual way. Forms were placed on the outside of the frame, and the concrete was shot from the interior. The density of the concrete applied in this way increased the weight, but it is estimated that cars of this size and design can be made weighing 23 to 24 tons. A new light-weight aggregate, known as haydite and invented by Stephen J. Hayde, of Kansas City, was used. This makes concrete said to weigh 104 lb. per cubic foot, with a compressive strength of 4450 lb. in 28-day tests.

The car was designed by J. B. Strauss and built by the R. F. Conway Co., while many parts of the equipment were contributed by the Illinois Central R.R. After 30 days' service on that road it will be turned over to the United States Railroad Administration. The



REINFORCEMENT FOR CONCRETE FLOOR, SIDES AND ENDS OF CAR

Concrete Car Co. has been organized by J. J. McCarthy, Joseph B. Strauss and F. E. Sullivan, of Chicago.

Business Notes

The Sullivan Machinery Co., Chicago, announces the establishment of a branch office at Edificio Oliver No. 3, Mexico City, in charge of Joseph F. Bennett. The appointment of Chester Mott as manager of the Denver, Colo., office, succeeding Wallace T. Roberts, resigned, is also announced.

Twenty-one years' of service have brought G. W. Burrell to the assistant vice-presidency of the Wellman-Seaver-Morgan Co. He will have entire charge of the company's work, both at Cleveland and Akron.

The Chicago Pneumatic Tool Co. announces the removal of its Cleveland district office from Room 813 to Rooms 406-408 Engineers Building, effective Mar. 1. The new headquarters will serve the company's interests within the Cleveland district. Ross Watson is district manager.

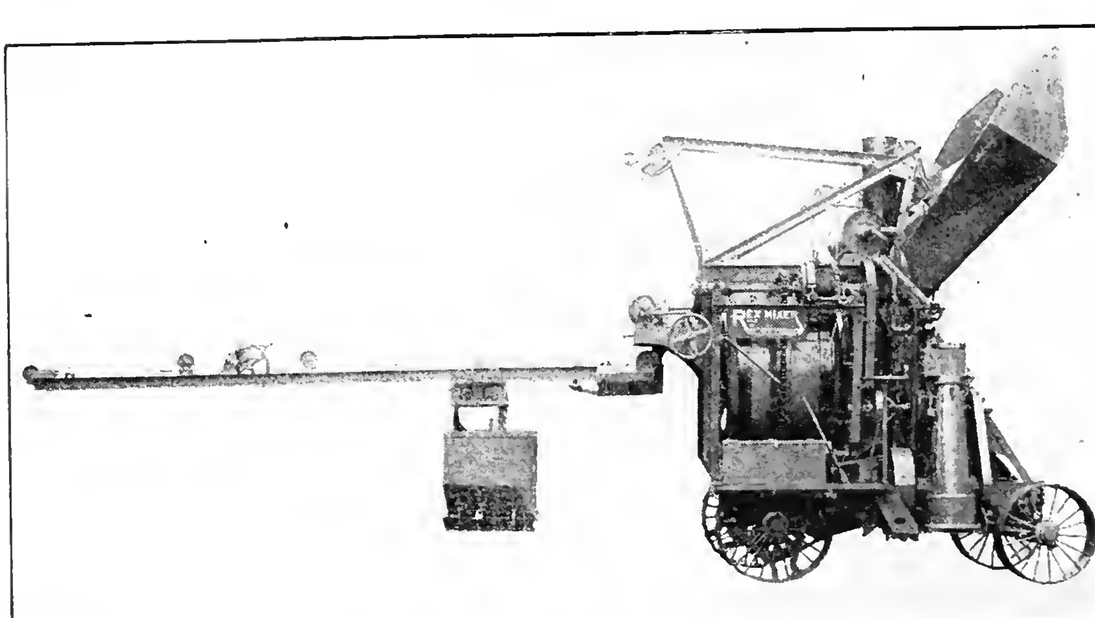
Turning from war to peace interests, the Associated Metal Lath Manufacturers have moved from Washington to their pre-war offices in the Swetland Bldg., Cleveland. During the war, Wharton Clay, who is the new commissioner, was connected with the Military Training Camps Association, in the work of placing men of special qualifications. The assistant commissioner is C. O. Powell, formerly with the Northwestern Expanded Metal Company.

Andrew Barr, who has been associated with the United States Wind Engine and Pump Co. since 1914, has accepted a position as superintendent of the foundry of the Waterloo Gasoline Engine Co., Waterloo, Iowa.

The Appraisal Engineering Co., Seattle, has opened offices at 409 Burke Bldg., as engineers and building contractors. Joseph Klein is superintendent.

New Paving Mixer Has Inclosed Transmission

A step toward automobile practice is marked in the concrete paving mixer field by the announcement of the 1919 model "Rex" 14-E, manufactured by the Chain Belt Co., of Milwaukee, shown in the cut. The sprocket chain drive is retained in the new model, which has rated forward speeds of 84 and 120 ft. per minute and a reverse speed of 90 ft. per minute. As suggested by its number, the machine has a wet concrete capacity of 14 cu.ft. It has a 90-in. loader, allowing the use of two wheelbarrows, and is equipped with either a 20-ft distributing boom or a 15-ft. spout, which receives the concrete at a height of 60 in. above the ground. The power plant is underslung, in order to lower the center of gravity. The overall width of the machine is 8½ ft., and the total height is 13 feet.



MIXER HAS INCLOSED TRANSMISSION GEARS SIMILAR TO AUTOMOBILE'S

A Consolidation of Engineering News and Engineering Record — McGraw-Hill Company, Inc.—JAMES H. MCGRAW, *President*

ENGINEERING NEWS-RECORD

A WEEKLY JOURNAL
DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, *Editor* — CHARLES WHITING BAKER, *Consulting Editor*

Volume 82 — NEW YORK, THURSDAY, MARCH 27, 1919 — Number 13

Time Economy in the Use of Society Lists

THE latest issue of the *Proceedings* of the American Society of Civil Engineers carries the information that the Publication Committee recommended to the Board of Direction, as a measure of economy, the omission of the alphabetical and deceased-members lists from the forthcoming "List of Members." If the society wants (1) to save money, (2) to economize in the time of its members, (3) to cease the absurdity of publishing a directory of the directory, it will eliminate the present alphabetical direct-you-to-the-proper-page-to-find-the-address list and consolidate the names of all members, no matter what the grade, into a single list. The national mechanical and electrical societies have long since done it. It is a time-saver. One search gives all of the information, instead of the two searches required now.

Criticism of Bureau of Public Roads Unfounded

RECENTLY criticism has been heard that the Bureau of Public Roads has been delaying the states in their Federal-aid work, the delay being attributed to the failure to appoint a new director. To ascertain the facts, *Engineering News-Record* sent telegrams to 10 state highway engineers, well distributed geographically. The answers are unanimous that there has been no delay. In fact, some of them indicate that there has been improvement. However, some of the officials feel that injury to the organization and work will result if the appointment of a director is unduly delayed. In this feeling all will concur. The sooner the new director takes office, the better it will be for the road-building interests of the country. Disorganization is bound to follow if the present uncertainty is allowed to persist much longer.

A Fair Day's Pay for a Fair Day's Work

IN THIS issue will be found a brief article, by J. B. Lippincott, which goes to the heart of one of the critical situations of the day—that of wages. Mr. Lippincott shows that on a certain operation excellent results were accomplished in an endeavor to persuade the men that, in order to maintain the war wage-scale, they had to give an adequate day's work. The closing down of the operation prevented carrying the work to a very much higher stage of efficiency, but the incident is sufficient to indicate both to employee and manager that the way out of present wage controversies is for the one to guarantee a fair day's work and the other to guarantee a fair day's pay. The disposition among employers, so far as we have been able to ascertain, is to maintain the present rate of wages, asking in return either pre-war efficiency or an efficiency readily attainable by the average worker. If the worker will see the need of fair production and will be guaranteed a good wage for it, many of our industrial difficulties will be quickly cured.

First Big, Worth-While Step In Compensation Efforts

LAST week's conference on salaries of engineers in railroad service, held under the auspices of the American Association of Engineers, marks the first big, worth-while step in the long discussion on compensation. Various societies have standardized the fees of consulting engineers, and here and there have even suggested the proper rates for employed engineers. For the first time, though, a nationally representative meeting of engineers has proposed a schedule of salaries for a large section of the profession. Furthermore, they propose to get action, to press home to the Railroad Administration the fairness of the approved schedule. The action at Chicago is certain to have a stimulating effect on the whole compensation discussion. It will give it definiteness. There is now a norm to which discussion can be referred. The men who did the work of the conference and the society, the American Association of Engineers, which arranged it, deserve great credit for their accomplishment. Every engineer will be with them in their future steps with the adopted schedule.

Resort to Primitive Tools Often Wise Plant Selection

SELECTION of a hand derrick instead of a more modern hoisting machine to place the considerable volume of stone required to repair the masonry dam described in *Engineering News-Record* of Mar. 13, 1919, p. 517, demonstrates a more alert perception of the art of plant selection than is apparent in many construction operations. With the multiplicity of highly perfected power tools, the constructor falls very easily into the habit of regarding the choice of a less modern tool as a violation of good practice. Instead, as was the case in the dam work at Willimantic, the truly scientific procedure often is to revert to a primitive tool. The installation of a power derrick on this work, however efficient it may be by itself, would have been an error in plant selection. The speed and output of the power derrick could not have been utilized, while the cost of getting the heavier plant onto the work and of keeping it supplied with fuel might easily have increased the cost per unit of output to a figure which would show no economy, compared with the use of a hand derrick. It is as easy to over-plant a construction operation as it is to fail to provide sufficient equipment. The resultant lack of economy is often quite as great.

A Forward-Looking Railway Convention

IN ITS record-breaking meeting at Chicago last week the railway engineering profession made full response to the call of the times. Coming after the stress and confusion of war railroading, the inspiring energy and hopefulness evident at the meeting gave unmistakable promise of a broadening and deepening of technical work in the railway field. Yet even during the war research was active in the solution of transportation problems. The notable studies of rail quality recorded on another page open the first definite prospect of distinct advance in this subject that has appeared in years. Remarkable work, too, was done in the study of bridge specifications, a foundation stone of structural safety. The greatest achievement of the past year, however, was the liberalization of thought among railway engineers of which the meeting gave repeated evidence. With new views on the engineer's relation to labor, and a coöperative spirit forming with regard to the manufacturers who aid in developing railway materials and methods, a basis is given for progress greater than that of any prior period.

Conference on Federal Public Works Department

A NATIONAL convention of engineers representing every branch of the profession, made up of delegates chosen by all classes of engineering societies, local and state societies as well as national, has been called by the Engineering Council to assemble at Chicago Apr. 23-25 to discuss the proposed Federal department of public works. Never before has it been attempted to bring the influence of the entire engineering profession to bear on a great project for public welfare. In fact, no such convention representing all branches of the engineering profession has ever been laid. The nearest approach to it was a convention held in Cleveland 33 years ago, or Mar. 31, 1886, when delegates from 23 local societies of civil engineers met to organize to further the project, then as now a matter of deep interest to engineers, for a national department of public works. It is not strange that the movement of that day failed of success. The total membership of all the 23 engineering societies which joined in that Cleveland convention 33 years ago was less than the number of members in any one of many of the representative local engineering societies of today, to say nothing of the huge roll of members in the national societies. More than 50,000 engineers will probably be represented at the Chicago convention. If the united influence of this great body of engineers can be put behind a well worked out plan for a Federal department of public works, at this time when the public is demanding greater efficiency in Governmental business, there is good hope for success.

Simple Tests Disclose Trade Skill

MANAGERS of the "practical" school as a rule believe that the engineer's methods of analysis fail when the problem of appraising applicants for work is up for solution. The work of a few pioneers in recent years has gone far to discredit this belief. Unfortunately, this work is not generally known. Even engineers do not know it well. And, because in all problems of human relations there is a residuum which does not break down under analysis, even some engineers have dismissed the problem as unsolvable by engineering methods. It is these conditions which lend special interest as well as value to the experience of the personnel organization of our new Army in appraising the trade skill of thousands of recruits. The general method of conducting trade-skill tests for Army workers were outlined on page 554 of last week's issue. The simplicity of the operation is exceeded only by the conclusiveness of the results obtained. The Army experience has demonstrated other facts of equal importance to construction and to industry generally. Trade-skill tests are expensive neither in time consumed nor in equipment required, nor in the cost of skilled direction. They operate as well in selecting men for the industries as in selecting men for warfare. They involve no previously unknown methods. War experience here, as in a score of other directions, has rendered a service to business.

Discussion for the Guidance of the Development Committee

SEVERAL members of the Development Committee of the American Society of Civil Engineers have recently expressed their disappointment at not having received from the members suggestions regarding the conduct and desirable activities of the society. Some local sections have given expression to views on certain topics, but on the whole the membership has remained inarticulate. Naturally, the Development Committee needs to have the best thought of the whole membership. Individual opinion, however, is not likely to be freely offered until the committee takes the initiative by presenting something concrete for discussion. It need not be the conclusion of the majority. In fact, alternative plans will be as effective in stimulating discussion as would a single plan more or less matured.

But while individual expression of views may not be readily forthcoming, there is another means—through studies and reports of local association of members—of learning what a large part of the membership desires. The Philadelphia and Pittsburgh groups have already pointed the way. Both have organized section development committees, which, in turn, have been divided into subcommittees paralleling those of the Development Committee itself. These local development committees have already sent to their respective associations reports that have had intelligent and eager discussion. At Philadelphia the report has been circulated confidentially to the members, in order that they may give it close study and be prepared to discuss it with greater thoroughness at the April meeting.

In both cases the local associations' representatives have attended the meetings and have looked upon the work as a process of formulating the opinion of the local members for their (the representatives') guidance.

What Philadelphia and Pittsburgh have done the other local associations should proceed to do. Then, as the conclusions of each section are formulated, they should be published. They will thus not only stimulate the thinking of the other sections, but also of individuals without local-section affiliations. The resulting discussion should furnish information and suggestions that will help the parent Development Committee in the discharge of its weighty but inspiring duty.

Road Contractors Must Prepare for Dry Concrete

CONTRACTORS for concrete roadwork must be prepared to alter their construction methods. The star of dry concrete is ascendant. Convinced by the tests of Prof. D. A. Abrams, described in *Engineering News-Record* of May 2, 1918, p. 873, many road engineers are barring the use of the wet mixes of past years. Specifications already prepared for considerable mileages of concrete road to be built this year call for mixtures so dry that they must be tamped. It is known that these specifications are but forerunners of others covering the work of whole states.

This change in concrete-road practice is of direct concern to contractors. New and different equipment will be required, and greater working capital will be needed to conduct construction operations.

In these conditions there is no reason for alarm. The danger, if there is any danger, lies in ignoring them. Nor need contractors anticipate a wholesale change to the dry mix in the specifications for this year's road construction. A few specifications will call for mixtures so dry that the concrete must be heavily tamped to flush the water to the surface. Most specifications will call for only moderately stiff mixtures, or for no change until engineers are more fully convinced that the mechanical means for handling abnormally dry concrete are assured. In the end, however, contractors must look forward to the use of drier concrete for road construction, a mixture so dry that it must be compacted by tamping, and they must be prepared to change their practices to meet the conditions.

New Prospects for Improving Rail Steel

WITH the discovery in recent months of a wholly new means for investigating rail quality, a start has been made toward the acquisition of new truths whose magnitude and importance can hardly be estimated as yet. Laboratories all over the country are engaged in examining good and bad rails by etching with strong acid, and they have begun to coördinate the interior conditions disclosed by the acid with failures of rails in track service. It is nearly eight years since the transverse fissure was discovered; yet in that period hardly as much advance has been made toward locating its source as within the past few months.

An appreciation of the power of the new method of study may be obtained from the light it throws on the part played by "bad heats." During the past years of investigation not a few rail men came to believe that fissure troubles reside not in the individual rail but in the ingot or in the heat. Yet this conclusion did not impress itself on all, and further conclusions of possibly great moment were thereby forestalled. With deep etching, however, the parallelism of acid-unsoundness and transverse-fissure troubles appeared early, and further investigation showed a tendency for all or a large part of a furnace heat of steel to be unsound in the acid test. It was natural to conclude that the transverse-fissure danger affected the whole heat or the part which the acid test pointed out as suspicious. Joining this conclusion to the known fact that, in many cases, two or more rails of the same heat had failed in the track, a tentative conclusion has been established that transverse-fissure troubles must be blamed on defective quality of the heat.

Two important deductions follow: First, that if one or two breakages in service give warning against all other rails of the same heat number, possible further breakages (or accidents) may be avoided by taking out these rails at once. Second, that there is more promise in metallurgical studies of rail steel and examination of furnace and mill conditions than in study of track service.

As the facts stood until recently, the case was equally unsatisfactory for both of the opposing theories: That overstress in the track is the cause of transverse fissures and that mill defects are the cause. Against the latter stood the fact that no defects of the steel could be discovered by any known method of examination, as well as the fact that the breaks develop on the gage side of the rail, where the service is most severe. On the other hand, the stress theory was confronted by the unanswerable objection that out of many like rails in a given stretch of track only very few developed transverse fissures. Moreover, light rails often survived where an adjacent rail of heavier section broke—though its stresses were lower; under the stress theory it should not have broken. Furthermore, a rail that had one transverse fissure often, or usually, contained several, and sometimes many, and it seemed undeniable that the material itself, the rail, was defective.

Today it appears clearly established that the stress action—that is, the production of a progressive or detail fracture—does not begin until a steel defect gives it a starting-point. The search is narrowed down to the nature of the defect that causes a star-shaped break, or a "gray spot," or a transverse fissure. Does nonhomogeneity of the metal, whether visible under the microscope or not, cause the trouble? Are there cracks in the steel, little discontinuities that never were welded up firmly, and that the acid seeks out and enlarges into sawcut-like gashes? Such questions are likely to be answered soon during the inquiry into what material dissolves out of the gashes made by the acid.

Doubtless, the defects revealed by the acid go back to an early stage in the rolling. Dr. P. H. Dudley's statistical demonstration that rails rolled from reheated blooms do not break seems to make this fact certain. Reheating allows the alloying elements of the steel to diffuse. It also, perhaps, furnishes heat enough for the welding up of cracks that developed in the ingot or during the blooming. But the latter probability is less attractive, in the light of the fact that direct-rolled rails often break; time of heating seems to be the factor, and this means diffusion rather than welding.

So close a similarity exists between the transverse-fissure trouble of rails and the "snowflake" trouble of nickel-steel gun forgings discussed at the American Institute of Mining Engineers' convention a month ago, that the tendency to look for identical causes is but natural. The rail question, however, is more easily solved, perhaps, as an independent study. In discussing snowflakes, in our issue of Feb. 27, 1919, p. 408, we spoke of the essential unity of steel study. It is more probable, however, that rail study will throw light on snowflakes than that the converse should happen. The new acid-etching process gives immediate promise of advance in our knowledge of rail quality.

Cost of Camp Utility Operation by the Construction Division of Our Army

Roads, Buildings, Fire Protection, Electric Service, Heating, Water-Supply, Sewerage and Sewage Treatment with Grease Recovery, Refrigeration and Railroad Service

By George W. Fuller
Consulting Engineer, New York City

THE history, functions, organization and major operations of the Construction Division of our Army were outlined by the writer in *Engineering News-Record* of Feb. 27, p. 416, and the organization set up by the Construction Division to operate and maintain the buildings and utilities at the Army camps was described by the writer in *Engineering News-Record* of Mar. 20, 1919, p. 562. Some of the operating records and costs are summarized in the present article. Efficiency in control of camp water-supply both as to quality and quantity is an outstanding feature. Among the more novel experiences is that of removal of grease from kitchen wastes in order to lessen the difficulties with floating solids and acid fermentation in the treatment tanks at the sewer outlets.

Roads—At the camps and embarkation ports alone there were during 1916 nearly 750 miles of highway. Since early August each camp and cantonment has received an appropriation of $15,000 for road maintenance. In addition to this amount, special sums of from $10,000 to $25,000 each have been alloted in the case of some camps for road reconstruction.

The original specifications call for four standard types of roads, but no single type was adopted in all camps and cantonments. The four used at the various places were bituminous macadam, asphaltic concrete, brick, and cement concrete. The main arteries of traffic were in general paved with one of these types, depending, of course, upon such factors as the availability of materials, the character of construction equipment, the nature of the soil, and the speed of construction. These roads, considering the rough usage which they received, have stood up very well, but almost constant repairs are necessary.

Buildings—Demands for roof repairs have been so great that special study was made to determine the cheapest effective method of making such repairs, taking into account the temporary character of the buildings in other than permanent Army posts. The buildings constructed since the spring of 1917 have for the most part been roofed with two-ply roofing paper. The drying out of decking naturally caused the roofing paper to buckle, in some cases to such an extent as to crack it or pull it around flashings, thus causing leaks. A good deal of damage was also caused to the roofs by walking on them for signal practice, for use as observation posts and similar activities at the camps. In co-operation with the Bureau of Standards, an economical method of roof repairing with plastic cement was adopted, and by the proper use of this material the roofs have been kept reasonably water-tight, at an annual cost of about 10c. per square. At the principal camps alone, for 1918 the average cost of maintenance and repair was $\frac{1}{24}$c. per cubic foot, while the total population housed approximated 1,000,000. On this basis the cost of maintenance and repair of buildings for the six-month period which ended with the calender year 1918 was $4.05 per capita, or $8.10 per capita per year. The total number of individual buildings which have to be maintained is nearly 55,000, with a combined volume of 1,705,625,000 cubic foot.

Fire Protection—As fire marshal, the utilities officer at each large project has organized an efficient and up-to-date fire company for the protection of buildings and stores. The general policies maintained in the design of the camps, of providing an ample number of hydrants and automobile fire trucks, and of leaving "fire breaks" and sufficient space between the individual buildings, has been well justified. At each camp the fire company has been organized at a strength of about 60 men, commanded by an officer corresponding to the municipal "fire chief," who has had experience in municipal fire department work. Similarly, the enlisted men, so far as possible, were chosen for their previous fire-fighting experience.

The fire loss per capita has been kept down to a remarkable low figure, considering the character of the construction. The total fire loss in the Army camps, with average populations of about 30,000 men during the year 1918, amounted to 46c. per capita as against the loss of $2.10 per capita throughout the whole United States. This is noteworthy in view of the fact that the standards of the National Board of Fire Underwriters designate as a low annual fire loss in municipalities one that is below $2 per capita. Thousands of fires, of course, broke out, but only four got beyond the buildings in which they originated, and in each case the camp fire department succeeded in saving a part of the building in which the fire started and a part of the single adjacent building to which it spread.

Electric Light and Power—One of the routine duties of the utilities officer in the field consists of seeing that the necessary generator capacity is actually available at the power station, that the transmission lines are af sufficient size and properly protected, that the necessary transformers and service stations meet adequately the demands, and that the electric energy is properly distributed where it is needed. The secondary distribution circuit, including street lighting, service entrances to buildings, all interior wiring in buildings, together with supplying and maintaining the electric power equipment of the pumping stations, refrigeration plants, laundries, and so on, all falls within the duties of the utilities organization. In the 32 organized camps and cantonments alone electric wiring averages about 1,000,000 ft., or 190 miles.

The average cost to the Government for electric energy has been kept down to about 2.5c. per kilowatt-hour. The cost of electric current varies according to local conditions. At Camp Lewis, Washington, with water-power generation, it costs approximately 0.9c. per kilowatt-hour, while at Camp Mills, with steam gen-

eration and under somewhat unusual conditions, it cost about 7.5c. The average per capita consumption for all camps is about 7 kw.-hr. per month.

Heating Service—In connection with the heating operations, the conservation of fuel has been of great importance. The records of the Maintenance and Repair Division show at 14 central heating plants a saving by careful operation alone of almost 50% of the estimated cost. The estimated daily average of coal required was 360 tons, while the actual consumption was 179 tons. These figures were taken from Northern camps, where the cost of the coal was \$8.21 delivered at the boiler houses, and the saving over the estimated requirements amounted to \$313,213. Something over 5,000,000 sq.ft. of cast-iron radiation are used in the camps alone. Tens of thousands of room heaters and stoves are used, and all must be kept in good order.

The amount of coal consumed in the camps reaches nearly 2,000,000 tons per year at an average cost of \$5.03 per ton delivered, or \$10.01 per capita per year. Approximately a third of the total cost consumed in all camps was used to heat buildings. For example, during the extremely cold weather of a year ago Camp Funston used 8640 tons of coal per month for heating purposes alone, and to heat the 2000-bed hospitals at Camp Dix during November, 1918, required 1271 tons.

Control of Water Supply

The average cost of purchased water-supply has been 8.16c. per 1000 gal., varying from 4c. at Camp Doniphan to 17.5c. at Camp Frémont. With an average total daily population in the larger camps of 506,882 persons, from January to October, 1918, inclusive, and a total daily consumption of 26,166,000 gal., the total daily cost amounts to \$2135 per day, or \$1.54 per capita per year for a daily average of 52 gal. per capita.

In a number of instances the Government maintains a booster station on the force mains in addition to the station at the camp or project, hence there is an additional item of expense. Although precise figures are not available it is estimated that 2½c. per 1000 gal. for boosting is approximately correct. This would make a total cost of 10.7c. per thousand gallons.

In the month of January, 1918, for example, when the peak per capita consumption was reached at the camps, one camp reported the maximum average per capita daily consumption for the month at 123 gal., while another reported the minimum average of 42 gal. The high consumption may be attributed to some extent to allowing water to keep running from the outlets to prevent freezing, and also to central heating plants without return systems. The water-supply in most cases is designed on a daily 55 gal. per capita basis at a pressure of 60 to 85 pounds.

The majority of the National Army cantonments have wood-stave pipe for their distribution mains, some 3,500,000 ft. in all having been laid in the National Army and National Guard camps. At Camp Dix there are approximately 19 miles of water main, one-third of which is cast-iron with leadite joints. There are approximately 25 miles of service pipe, ranging in size from 3 to ¾ in. and about 15,000 water fixtures.

By careful test at Camp Dix it was determined that fixture waste and legitimate use accounted for 400,000 gal. of a minimum night rate of 600,000 gal. per 24 hours. It was also determined that the filling of the railroad water tank accounted for another 100,000 gal. This leaves an unaccounted-for flow of 100,000 gal. daily, which may be attributed to underground leaks. At Camp Grant, with a total of 48,840 ft. of main and 55,900 ft. of service pipe, a careful test showed a total underground leakage of 35,588 gal. per 24 hours.

Soon after the camps and cantonments were placed in operation it became apparent that at some the water consumption in winter exceeded the 55 gal. per capita per day basis. Inasmuch as military discipline was commonly supposed to be a corrective for various shortcomings, a campaign of water conservation was undertaken through the issuing of military orders and large posters. But this did not bring about the desired result in all cases. From the very start round-head self-closing faucets were repeatedly recommended by the advisory engineer for water-supply, but for various reasons their use was not then authorized. Since last July self-closing faucets have been used on all new construction.

Attention Directed to Defective Fixtures

Investigation revealed large quantities of water being lost through careless use and defective plumbing fixtures. It was felt that efforts to control this waste would be productive of better results in less time and with less labor than to center major efforts on elimination of the usually small underground leakage.

Some of the more common methods for restricting waste included the lowering of float balls in flush tanks and the reduction of pressure by inserting, back of the faucet, rubber tubing, buttons with two thread holes, glass marbles or tapered lead plugs with small orifices. The latter were inexpensive and easily installed. Since July, 1918, water consumption at practically all camps has been kept within the established quantity.

No case of water-borne disease has so far been attributed to a water-supply installed and operated by the Construction Division.

Sewerage—The construction of 455 miles of sanitary sewers for the 16 National Army camps, approximately 300 miles for the National Guard camps, and approximately 400 miles for various special projects, was an undertaking of no small magnitude. During the 15 months the sewer systems have been in operation very few defects have developed, a rather remarkable fact considering the haste and other unusual conditions under which they were installed

Sewer sizes range from 6 to 30 in. Manholes were designed to be built as cheaply as possible, and were provided with wood covers. During the past summer most of these covers were equipped with locks to prevent the throwing of garbage or refuse into the manholes.

Every effort is made to prevent the access of surface water and the infiltration of ground water to the sewers, particularly at camps having sewage-treatment plants. Utilities officers were instructed to watch for any indication of surface water during periods of rain, and to use every effort in locating any defective sections. Investigations at a number of camps showed that in the haste of construction the manhole tops had not been made high enough and that surface water was gaining access to the system. Orders were issued that all such manhole tops should be raised.

At a few camps trouble was experienced with sand, which found its way into the system through such low manholes as are mentioned above and partly filled the first compartments of the settling tanks. In one or two

instances the trouble was due to defective sections of sewer which had to be relaid. In the few instances where clogging of sewers has been reported, grease has usually been the cause.

Grease—One of the most interesting developments in connection with sewerage at Army camps has been the importance of intercepting grease from kitchens. This subject, up to the time the camp sewage-works were put into operation, had been practically overlooked.

The typical plans at first adopted in connection with sewerage systems at camps provided that an 18-in. tile grease trap should be installed on each kitchen line.

The flow from kitchens comes in sudden gushes. Experiments conducted at Fort Myer by the Sanitary Corps showed that the average flow per capita per day from the kitchens was 2.4 gal. A maximum rate of flow of 1.5 to 2 gal. per capita per hour was observed. However, these sudden gushes cover short periods varying from 5 to 15 min. During a 10-min. interval, therefore, the flow from a kitchen serving 200 men on the basis of the above figures would be from 50 to 67 gallons.

A trap is required of sufficient capacity to take care of these sudden surges, to allow for some cooling of the liquid in passing through the trap, and to permit the accumulation of grease during the period of a week without any great reduction in the capacity of the trap. The tile traps were entirely too small to take care of the peak flows. At such times grease which accumulated in the trap was partly washed out through the outlet. The shape of the trap also has a great deal to do with its efficiency. For instance, the outlet must be so arranged as to prevent as far as possible accumulation of organic matter in the bottom. Traps of the new type installed at the various camps (see sketch) had capacities ranging from $\frac{1}{4}$ to $\frac{3}{4}$ gal. per capita, based on the number of men served in the kitchen. The early records of quantities of grease recovered indicate that a capacity of $\frac{2}{3}$ gal. per capita for the latest type of trap is perhaps sufficient. Such a trap requires cleaning weekly.

Camp data from various sources during last autumn show that the quantity of grease recovered per capita per year is about 10 to 12 lb., and the market value of this grease at the present time is about 10c. a pound, or in round numbers, $1 per capita per year. The population of all the principal camps during the past summer was about 1,000,000 men. If all the kitchens had been provided with traps the total potential income per day, on the basis of the above figures, would have been $2750, equivalent to $1,000,000 per year. Thus, the installation of grease traps, instead of being an item of expense, should be a source of profit. However, the money returned is in reality a secondary consideration in comparison with the needs of these traps for protecting the sewer lines and preventing grease from interfering with the proper functions of tanks at the treatment works. Grease trap skimmings contain some water and impurities and will apparently yield about 65 to 70% of grease.

Cold weather promotes the separation of grease, as shown by records from grease traps of various capacities during a period beginning about the middle of November last, as follows:

CAMP MERRITT

Capacity Gals. per Capita	Number of Cleanings	Pounds per Capita per —ea
0.30	3	17.9
0.50	7	7.2
0.60	82	16.1
0.70	22	7.4
0.80	9	11.8
0.90	3	11.1
1.00	12	27.3
2.00	2	77.7
3 00	16	100.1
	156	

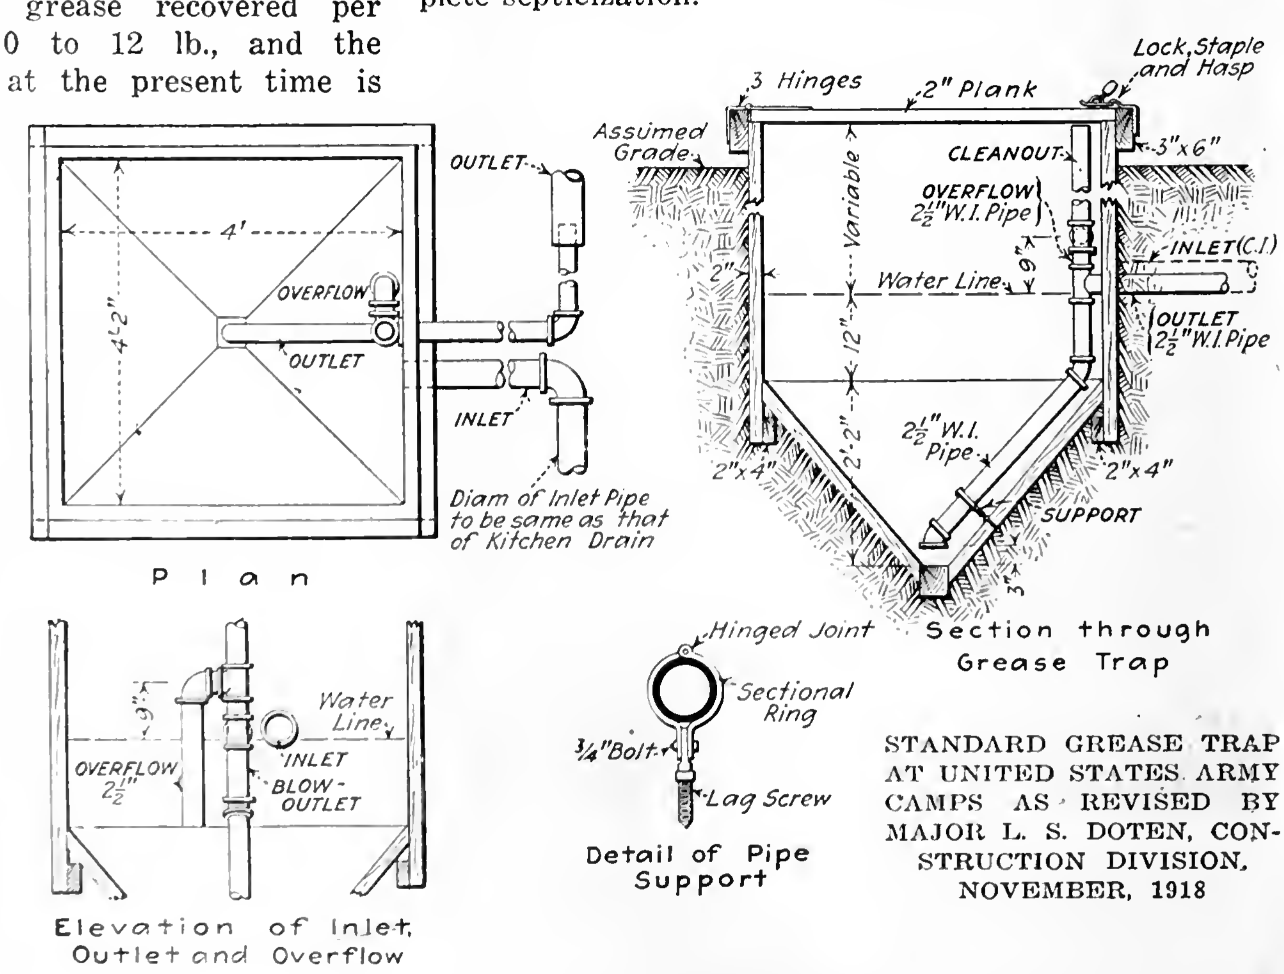
CAMP MEADE

0–0.5	2	11.7
0.5–1.25	143	18.8
1.25–2.00	68	23.2
2.00–3.00	27	69.7
3 00–4.00	25	65.7

The capacities refer to persons served in the kitchen, to the drain of which the trap is attached. These data show advantages in still larger traps than were installed last summer. At some institutions a trap of 2.5 gal. per capita is favored. More data, especially in regard to summer conditions, are needed.

Tank Treatment of Sewage—Chlorination has been generally practiced at the outlet of the camp sewers, but tankage is the feature most worthy of comment in this article. Briefly, the tanks were unusually small in size, about 10 gal. per capita connected with the sewers. At some plants, as at Fort Myer, Camp Sherman and Camp Custer, septicization became established more quickly and completely than at other camps.

At all plants the freshness of the sewage and the unusual grease content made the sewage solids in the tanks float to a large extent, as compared with the sedimentation more generally noted at city plants. The grease, furthermore, seemed to promote acid fermentation, which generally interfered with prompt and complete septicization.



STANDARD GREASE TRAP AT UNITED STATES ARMY CAMPS AS REVISED BY MAJOR L. S. DOTEN, CONSTRUCTION DIVISION, NOVEMBER, 1918

Absence of funds retarded the program in the spring and early summer of 1918, but solids were removed promptly and carefully, beginning in July. The small tanks have much to be said in their behalf in connection with an efficient operating schedule and adequate grease removal arrangements. Larger tanks (35 gal. per capita) were ordered installed at some of the camps, especially those whose capacity was generally enlarged.

Refrigeration—Data indicate that it costs about $2 per capita per year to operate camp refrigeration plants. These plants comprised a meat-storage room and an ice factory.

Railroad Maintenance—There are 844 miles of railroad at the camps, terminals, depots, etc. Averages of maintenance records show costs of about $1400 per mile per year.

Concrete Consistency Measured by New Device

Method Developed for Concrete-Ship Work Determines Amount of Water to Use in Field Operations

By Herbert A. Davis

Engineer, Concrete Ship Section, Emergency Fleet Corporation

DEVICES to determine the proper consistencies of concrete have been put forward from time to time, but, so far as the writer has noted, none has been put into practical use. In the concrete ships now under construction by the Emergency Fleet Corporation, however, a field instrument has been developed that has proved quite satisfactory.

Soon after its inception the Concrete Ship Section of the Emergency Fleet Corporation recognized that the concrete to be used in the construction of concrete vessels must be of a high quality and special character, due to the relatively thin concrete sections, high steel areas and high working stresses employed for the purpose of reducing the weight of such ships to a safe minimum. Furthermore, it was seen that the concrete for such construction must not only have sufficient strength to meet the high stresses it is called upon to carry, but such concrete must be sufficiently mobile or workable properly to fill the forms and completely embed the reinforcement, with reasonable care and workmanship.

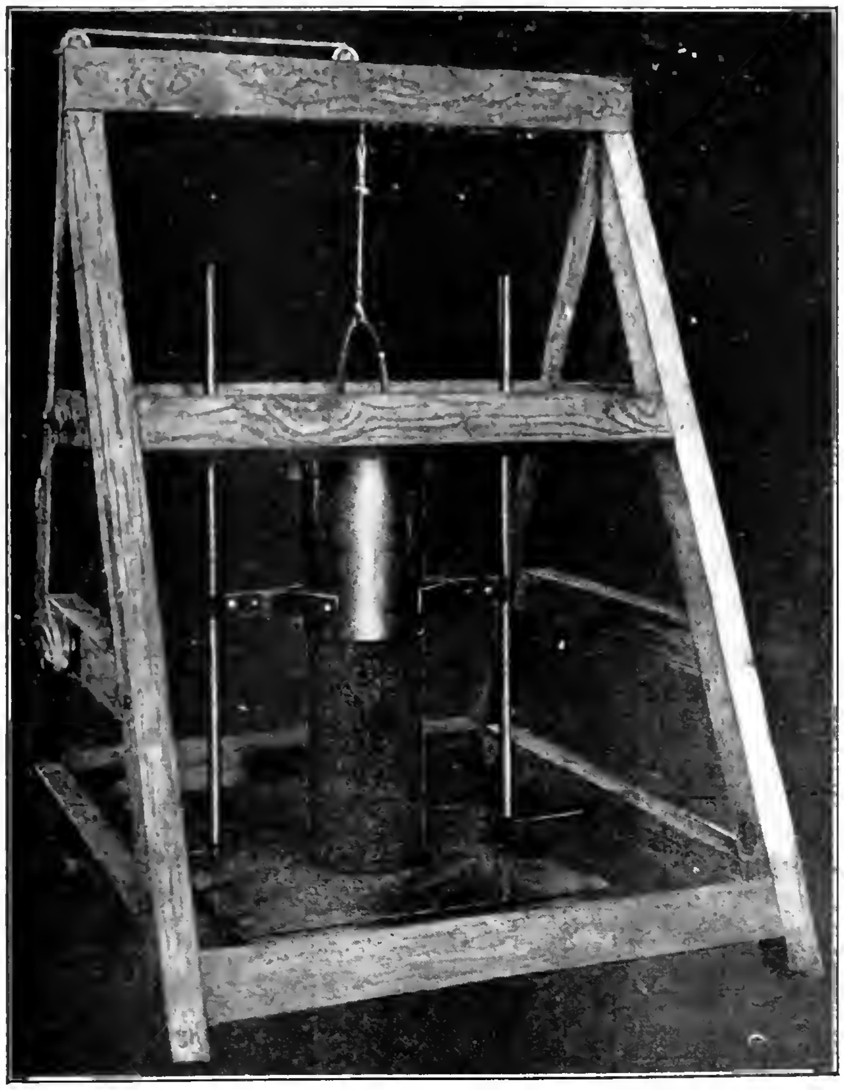


FIG. 1. CONCRETE WHICH DOES NOT DROP IN THE TEST IS TOO DRY FOR PRACTICAL USE

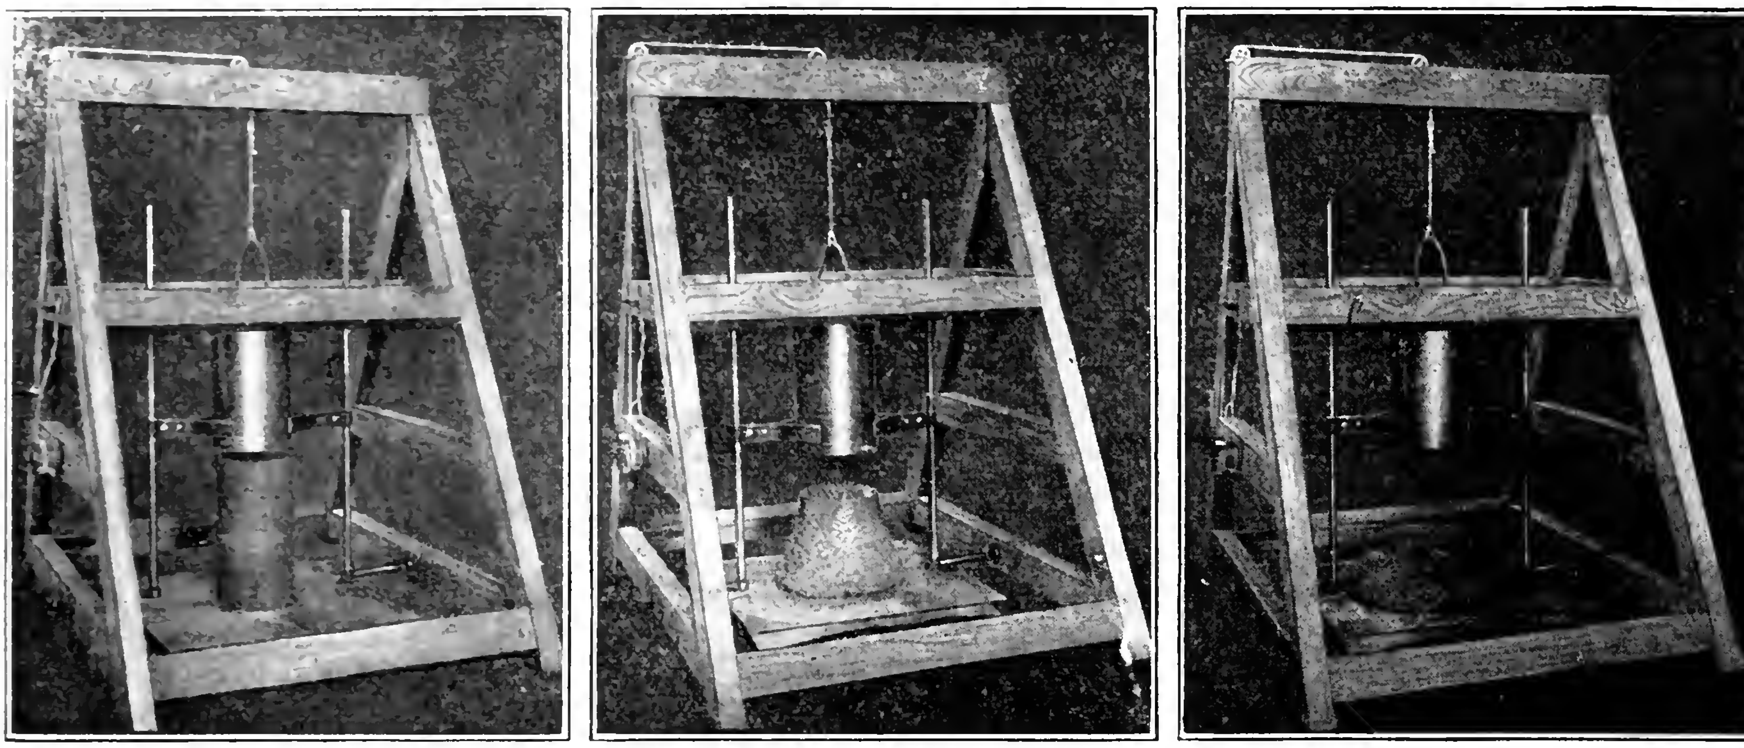
With these factors in mind experiments were made in the laboratory on a large number of materials as aggregates, used in different proportions and with varying amounts of water—that is, with different consistencies. From such studies the aggregates and proportions to be used in concrete-ship construction at various places were established, and data as to the effect of varying the water content of such concretes over a reasonably large range were obtained.

Assuming that all the concrete materials as delivered on the work are inspected to guarantee their quality and uniformity, and that steps are taken to insure the proper proportioning and mixing of the concrete, there still remains the need of a reliable means of regulating the amount of water which the laboratory studies indicated was required to produce a concrete of the strength and workability desired. In the field it has been noted that where the operator judges the consistency of the concrete by means of the eye, such concrete is far from uniform in most cases, and there is a general tendency to use an excess of water far beyond that necessary to give the desired mobility. Furthermore, it has been observed that the judgment of different operators, depending on the superficial appearance of the concrete, as to what is the desired consistency will vary widely.

In an effort to meet this obvious need of a reliable criterion for determining the proper consistency of concrete, the apparatus described has been developed. This consistency apparatus consists essentially of a metal cylinder whose inside surface is perfectly smooth, mounted on metal slides that direct the movement of the cylinder so as to be truly vertical, and this cylinder rests on a smooth glass plate supported horizontally and independent of the supports of the cylinder.

To operate this apparatus, the cylinder resting on the glass plate is filled as a mold with the concrete, the top surface is struck off level and the metal cylinder is slowly raised, leaving the concrete unsupported. It was found that this unsupported concrete took various shapes, dependent on the amount of water used in gaging the concrete. Furthermore, over a considerable range it was noted that the loss in height of the concrete cylinder on removal of the metal cylinder bore a definite relation to the amount of water used in gaging the concrete.

In the original experiments both the loss in height



FIGS. 2 TO 4. CONCRETE CONSISTENCIES SHOWN IN NEW TEST MACHINE

Fig. 2. While probably giving the maximum strength, can only be used in plain concrete work, such as sidewalks, concrete roads, and in large mass work. Fig. 3. Can be successfully used in practically all ordinary reinforced-concrete work, with excellent results. Fig. 4. Suitable for use in concrete-ship construction where it can be placed with reasonable care in spite of the thin concrete section and high steel areas employed in the design of such vessels

of the cylinder and the diameter of the base when left unsupported were measured, but it was found that the loss in height was a much more reliable criterion for determining the amount of water used. The measurements taken of the diameter were somewhat irregular, but in all cases, where care was taken to produce a symmetrically shaped figure, the diameter of the resulting cone was fairly reliable as a measure of consistency

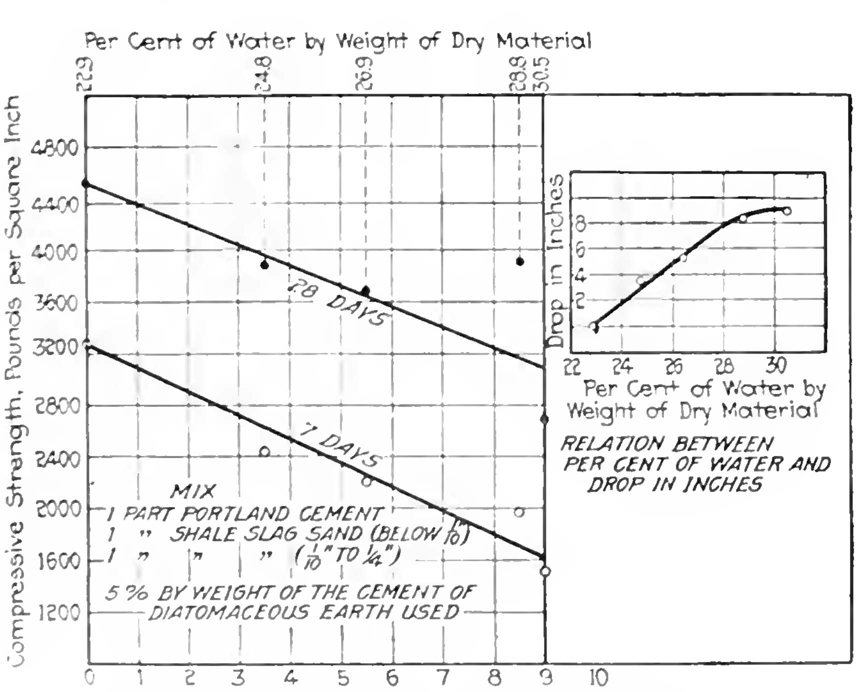
Typical curves, showing the relation between compressive strength, the amount of water used and the loss in height of the unsupported concrete cylinder, as determined by this apparatus for two different concretes, are given.

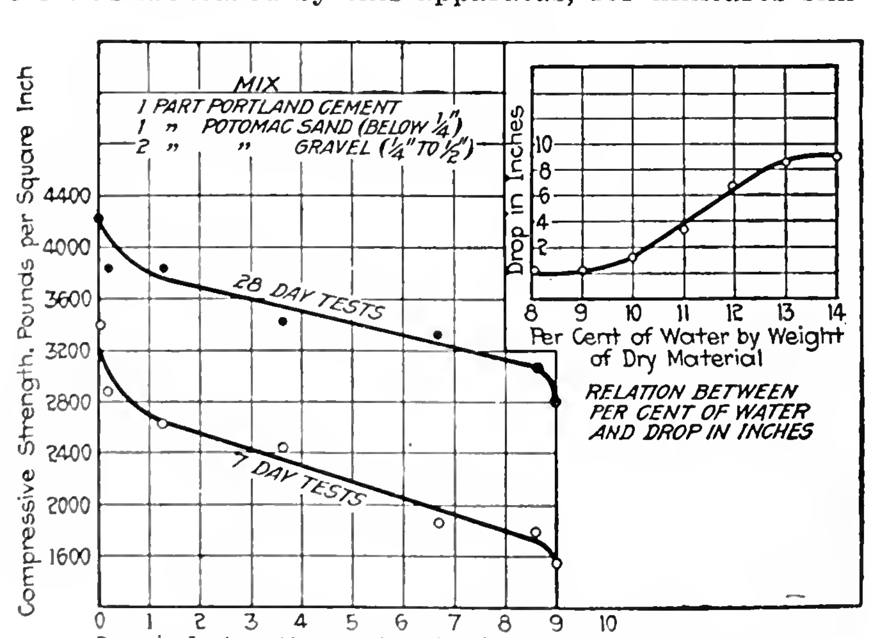
It should be recognized that the aggregates as stored on the work have varying moisture contents, which would materially modify the amount of water needed to produce a given consistency in the field, and further experience has shown that even with mixers equipped with water-measuring devices it is difficult to obtain the same amount of water in each batch. For these reasons it was deemed necessary to measure the consistency of resulting concrete with the "consistency machine" to determine the actual amount of water in the concrete, and to decide, from previously made laboratory studies of such concrete, whether the amount of water used was in excess of that necessary to give the required strength.

Practically, this means that in the field the loss in height of the concrete cylinder as measured by the "consistency machine" should not exceed a given maximum percentage of its original height.

In fixing a maximum limit of drop permissible for the consistency of concrete in the field, the general tendency of contractors to use an excess, rather than too little water, was in mind. It is believed, furthermore, that a certain amount of freedom should be permitted the contractor in this matter of consistency, provided he does not produce a concrete that is too wet. Accordingly, in the field work the effort was made to secure a concrete in which the drop was approximately 75% of the original height of the cylinder—that is, nine inches.

The consistency of the concrete which has a drop of 9 in. as measured by this apparatus, for mixtures sim-





FIGS. 5 AND 6. EFFECT OF WATER ON CONCRETE CONSISTENCY AND DROP AS SHOWN IN TESTING MACHINE

ilar to those used in the construction of concrete ships, may be described as semi-fluid or very mushy.

This method of controlling the amount of water used in the concrete has been tried out on practically all the ships or barges constructed to date, and it may be said to have accomplished with a reasonable amount of success the purpose for which it was designed, as attested by the results of tests made on the concrete cylinders taken from the work. This was accomplished with little or no interference with the work, and in general the consistency of concrete as regulated in this manner satisfied both the contractor and the Government representatives.

The author wishes to express his appreciation to G. V. Marconi and Watson Davis, of the Bureau of Standards, for assistance given in obtaining some of the data published in this article.

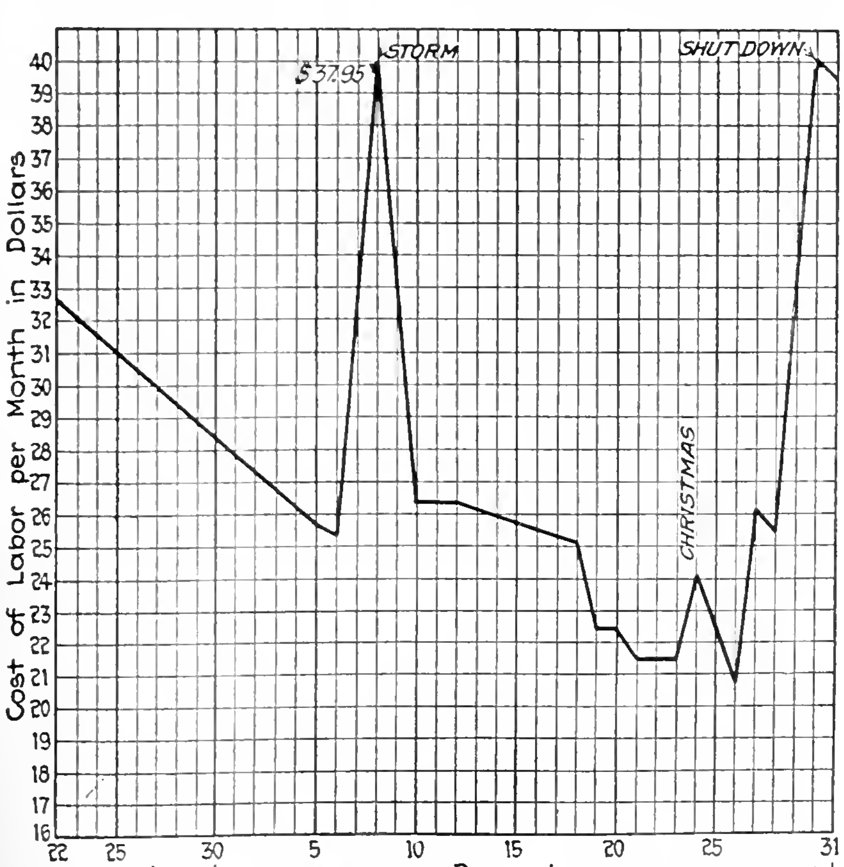
Unit Costs Lowered Without Cutting Wages

By J. B. Lippincott

Consulting Engineer, Los Angeles, (recently engaged in war work in the East)

During the war, high unit costs of construction have been due to the low output per man-day rather than to high wages, though the latter is, of course, a factor. Whether the bricklayer is paid 65c. or 85c. per hour is less important than that he has reduced his output from 1000 to 300 bricks per day. The experience here related and illustrated in the diagram shows strikingly the effect of increasing output, for the wages were not changed.

The incident is all the more important because the present inactivity holds grave possibilities, a fact realized by the Government, financiers and others. Labor is organized because it has to be for its own existence. It has taken advantage of its opportunity during the war to advance its rate of pay. I believe from personal contact with the unions that the skilled trades will not reduce that scale. The wage of common labor probably will go down, as it is not organized. However, *it is more important that wages be stable than that they be lower.* As compared with war conditions, overtime, which is paid at the rate of time and a half or double time, has been eliminated. This means a substantial reduction in the average wage rate per hour. I believe mechanics will endure much and go hungry a long time before they will reduce their scale. On the other hand, it is folly for them to try now under existing conditions to ask for an increase. It should be the problem of all to work for a resumption of business and to avoid placing any obstructions in the way.



COST OF BRICKWORK JOB ON ATLANTIC SEABOARD, NOVEMBER AND DECEMBER, 1918

The diagram shows the decrease in the labor cost of laying brick at a point in eastern Pennsylvania, following the signing of the armistice. The wage was 87½c. per hour. The writer was assigned to this work Nov. 16. The project was suspended Dec. 27; consequently, the unit costs cannot be given for a greater range of time. The costs were averaged for the week. The sharp rise Dec. 10 was due to interruption of the work by storms. That on Dec. 27 was due to the shutdown. Christmas week also shows a peak.

This diagram is fairly typical of other decreasing costs. The general decrease was brought about as follows: Overtime was eliminated as labor became more abundant. The personnel was much improved by a process of segregation. Those that remained did more work. The output per man-day was nearly doubled. The cost in November (1918) was outrageously high. It remained too high by far when the job was shut down from Washington, but there was a reduction in labor costs from \$33 to \$20 in 37 days. This reduction in cost was accomplished during a period of increasingly bad weather and in spite of much rain and bad roads. If the work could have been continued through to spring weather the reduction would probably have continued down to a reasonable unit cost. *No reduction was made in the wage.*

The union local and state officials took a keen interest in assisting in improving the unit costs. They realized that this should be done in order to encourage resumption of normal conditions. They also appreciated that if improvements were not shown by their trade other trades would supplant them—for example, that concrete buildings would supplant brick structure. In other words, the union in this case was an agent in helping to improve conditions.

This experience is a suggestion for reducing unit costs elsewhere, a move essential for the resumption of building. It is difficult to accomplish, doubtless, but probably far less so than to attempt to reduce the wage scale. Moreover, the possible results offer greater opportunity for larger cost reductions. The most effective way to reduce these costs is to adopt a piecework policy. If this is untenable, then the establishment of a reasonable day's output per man should be sought. At least in one case organized labor coöperated in this policy.

It is to labor's interest to assist in establishing efficiency so that it may not be vitally necessary to reduce the wage scale or defer starting new work.

Stream Flow Article by C. H. Pierce

The article "New England Rivers Have Similar Run-Off Characteristics," in *Engineering News-Record* of Mar. 20, 1919, p. 577, should have been accredited to C. H. Pierce, district engineer, United States Geological Survey, Boston, Mass., as author.

Railway Engineering Association Has Active Meeting

Tentative Rail Specifications Mark New Views of Quality and Tests—Rail-Joint Test Methods Adopted—Proposed Bridge Specifications to Be Reconsidered—Large Attendance and Atmosphere of Coöperation

IMPORTANT progress in technical railway matters, progress made despite unfavorable conditions, was put on record by the annual meeting of the American Railway Engineering Association at Chicago last week. In the fundamental subject of rail quality and rail testing a new field of study was opened up, and improvement of the specifications for rails to apply the new views was begun. Even more active work centered on the subject of steel bridges. A radical revision of the standard bridge specifications was worked out during the year, but the association, at its meeting, decided that it could not be accepted without full consideration, and referred the draft back to the committee for another year.

Significant of the unusual success of the meeting was the record-breaking attendance. Over 500 members were registered, a number considerably higher than at any previous meeting. In part, this is credited to the action of the Federal Railroad Administration, which, recognizing the importance of the technical studies carried on by the association, urged the various Federal managers to induce as many members as possible of the engineering organizations to attend.

The atmosphere of the meeting expressed the unusual character of present railway conditions and the exceptional importance of the railway engineering work that must be done during the next few years. President-elect Earl Stimson brought this matter to the fore in his inaugural remarks at the close of the meeting, in urging the technical committees to early and energetic attack on the problems submitted to them.

Relations to Railway Managers and to Manufacturers

New conditions will surround the association's work henceforth, due to the formation last month of the American Railroad Association as a consolidation of and successor to several executive and technical railway associations which heretofore covered the field—the American Railway Association (executives), the Master Car Builders' and Master Mechanics' Associations, and others. An engineering section of the new American Railroad Association has been created, but the Railway Engineering Association will remain independent of it, though actually furnishing the substance for the recommendations and conclusions which that section will report to the larger body.

More coöperative relations to manufacturers have also come into fairly definite prospect. President C. A. Morse, in his address to the meeting, laid special stress on the results accomplished by the committee on track, in working out new standards for frogs and switches in collaboration with manufacturers. It has been the policy of the association in the past to restrict its committee membership rather closely to railway men, in sharp distinction from the policy of the American Society for Testing Materials in balancing its committees as between producers and consumers. The spirit of President Morse's words may lead to a liberalization of the committee work in this latter direction, and some steps of the kind have already been taken by the rail committee.

An outstanding feature of the rail committee's report is a new method of studying rails for interior defects, contained in a series of reports on special investigations. The method consists of etching horizontal sections of the rail head with strong acid, hot, for several hours. It produces remarkable pitting or fissuring in certain rails, and all observations so far indicate that this pitting and the occurrence of "transverse fissures" in the rail while in track service are intimately related. Studies of defective rails by the "deep-etching" method are being made in rail laboratories all over the country at present. A brief summary of the subject is given in another column.

Among the other special-investigation reports presented by the committee are: Tests of various splice-bars (summarized on page 611), the quick-bend test by W. C. Cushing, interior transverse fissures by P. H. Dudley, and a statistical study of the service obtained with narrow-head rail (the so-called frictionless rail) on curves. This rail was found to be in use on about 25 roads, with results that are in general satisfactory, the rate of rail wear being reduced in most cases.

Besides these several matters covered by the report of the rail committee, there was discussion of the relations of wheels and rails by the track committee and on curve wear of rails by the committee on economics of railway location.

Proposed Rail Specifications Raise Quality and Provide New Test

Small but important changes in the association's specifications for steel rails, proposed by the rail committee, led to a call for coöperative work from the manufacturers' rail committee. The changes would (1) result in harder rails; (2) make more severe the criterion of acceptance of rails, and (3) establish a radically new form of test as an alternative to the time-honored drop test. The practicability of furnishing rails under existing mill practice would thus be affected, and, as stated by the manufacturers' committee, the mills have had no opportunity to consider the new test and acceptance requirements properly. In acknowledgement of this fact, a joint meeting of the two interests is to be arranged for, where differences of view may be considered and ironed out. The proposed specifications are in the meantime to be published only for consideration and discussion during the coming year. The essential changes from the present specification are the following: The required percentage of manganese in open-hearth rail of all weights is raised by 0.10%, making the limits read 0.70 to 1.00%. For the heavy weights of open-hearth rail, 111 lb. per yard and over, the required amount of carbon is raised by 0.05%, to the figures 0.67 to 0.80%. Both changes mean harder rail. At the same time, however, a higher ductility is demanded, the elongation (in drop test) being

changed from 6% to 8%. Furthermore, acceptance is made less easy by the requirement that all three drop (or bending) tests representing a given heat must pass if the heat is to be accepted.

Hitherto, the drop test has been the determinative physical test of rails. Experience on the Pennsylvania R.R., however, has developed so clearly and convincingly the value of a bending test made in a hydraulic press, that the committee adopted this test as an alternative to the drop test. The bend test is specified to be made with a 350-ton press on a 48-in. span, and autographic records of load and deflection are to be taken; the test is to be made preferably with the rail head in tension.

The specifications contain an unusual "information" clause, which states that transverse fissures have been more numerous in the product of mills that roll rails direct from the ingot than in material rolled from reheated blooms; it also states that six mills reheat the blooms and eight roll direct. The clause makes no recommendations or requirements, but contains a note stating that it is given merely as information derived from the statistics of rail failures.

Standard Specification for Tests of Rail Joints

Elaborate experimental studies of the strength of rail joints made by the Altoona laboratory of the Pennsylvania R.R. brought out so much valuable information concerning rail joints that the Rail Committee formulated a specification of test methods for rail joints, with a view to securing comparable results from tests made at different laboratories. The test is to be made in a press, the rails being supported on two supports 48 in. apart and the load applied over the joint midway of the span, measurements of deflection and set being made at 3000-lb. intervals of load. From the results of the test the efficiency of the rail joint is to be computed as the ratio of the elastic limit of the rail joint (in pounds) to the elastic limit of the continuous rail. This efficiency is to be stated both for head up and for head down. Furthermore, the rigidity of the joint is to be stated, expressed as the ratio of the deflection at the elastic limit of the joint.

By vote of the meeting this test specification was adopted, and is to be included in the "Manual."

Under the chairmanship of O. E. Selby, the committee on iron and steel structures studied and reported on several bridge subjects. By far the most important of these was the association's standard specification for steel bridges, which was first adopted in 1906 and was slightly revised several years later. Wholly new specifications were drafted by the committee.

They differ externally from the old ones in being much more elaborate as to design details and workmanship, having nearly twice as many clauses. A new train loading is specified—Class 60 in place of Class 50—but the Cooper type of engine and train is retained. The Turneaure impact formula is substituted for the old Schneider formula. Secondary stresses are taken into account. Reduction of live load on multitrack bridges is allowed. Reversed stresses are treated in a new way. A parabolic column formula is substituted for the old straight-line formula, and the limit of 12,000 lb. per square inch is fixed as the basal figure of column loading in place of the former 14,000 lb. In all parts the proposed specifications represent a wholly new departure from the old. However, they were printed so late that they did not reach the members of the association until two days before the convention, so that study with a view to adoption by the meeting was impossible. For this reason, after discussion on the floor revealed serious differences of opinion, the committee's motion that the new specifications be adopted in place of the old and printed in the "Manual" as standard was declined, and the subject was referred back for reconsideration during the coming year.

Remarkably broad discussion developed, in spite of the late printing, and points of fundamental importance to bridge design were raised. A few notes follow.

W. H. Courtenay questioned the ambiguity of the requirements as to lateral forces, wind effects being apparently omitted from an important clause. F. E. Schall asked whether the new specifications will produce weaker or stronger bridges than the old; until careful study can answer this question, they should not be made standard.

Referring to the clause reducing the live load on multitrack bridges, J. J. Yates suggested that the center girder in a 100-ft double-track bridge will be burdened with 70% impact under the new clause, as against 60% under the old. The new would increase both floor and girders, but experience shows that many floors are weak while the girders are still adequate.

A wholly new basis of design was advocated by A. C. Irwin, a member of the committee but not in agreement with its conclusions. He urged that bridges must be designed with a view to carrying the heaviest loading likely to come on them, and that designing for an artificial loading without much margin over present-day railway service makes it necessary to use low unit-stresses, the latter giving the margin necessary to provide for future load increase. An unbalanced bridge is the result, and one that is not designed for the heaviest load that may come on it. The cure for this condition is not the proposed specification, but one that will provide for the heaviest possible loading and allow the highest unit-stresses for this. With low unit-stresses there is continual trouble from the effect of the ratio of dead load to live load. Mr. Selby replied that these arguments had been considered very carefully. The committee recognized that low unit-stresses do not give a balanced margin for live-load increase, but gave heed to the psychological effect of specifying very high dead-load stress and an enormously increased live load.

The Proposed Specifications Criticized

E. A. Frink, characterizing the proposed specifications as an admirable piece of work, said that many serious faults need to be corrected. The loading adopted is the principal point of trouble. With Class 60 the engine loading is about 8800 lb. per foot, while heavy Mallet engines give about 8000. For present service the use of Class 60 gives an uneconomical bridge, with too much metal in the trusses and too little in the floor, in long spans. It is time to adopt a loading nearer the actual than is the Cooper series; the association should devise a new standard loading.

Moreover, it is questionable whether a loading as high as Class 60 should be prescribed. Such a capacity is not needed everywhere, and even Class 50 is not needed in some regions. In view of the great influence exerted by a bridge specification printed in the

"Manual," it will be hard for a bridge engineer to use a lower loading than Class 60 even if the conditions on his line justify it, and for this reason the best course might be to omit specifying a standard loading. In that case, the specification would say that bridges should be designed for the actually used train loads, with a given margin for probable increase of train weights. Mr. Frink also criticized the stresses in cross-ties as too high, and commented on the enormous loading specified for floors composed of transverse beams —over 25,000 lb. per linear foot of track, static equivalent.

Criticism was presented also by P. B. Motley, although a member of the committee. He asked that the specifications be referred back for further consideration. The new specifications of the Engineering Institute of Canada, drawn up under his chairmanship, were arranged to present successive subjects in the order of design, and differ in arrangement from the proposed specifications. It is necessary to have a Canadian specification to which Government bureaus can refer by name, and though it is desirable to have it agree with the American, this result could not be reached during the past year. However, there should be no international boundary in science.

European Plan Is Suggested

After dealing with several specific points, Mr. Motley said that he largely agreed with Mr. Irwin, and felt that the specifications "are not yet down to brass tacks in design." If the Mallet engine were to be adopted as basis of bridge loading now, we might have a quite different engine in ten years. It may therefore be wise to adopt the European plan of designing for a wisely selected uniform load.

Prof. F. E. Turneaure, speaking for the committee, dealt with the question of basing design on ultimate (maximum) unit-stresses.

Some years ago the association adopted 26,000 lb. per square inch as the stress defining the limit of safety of an old bridge. The committee considered whether this method could be applied to the designing of a new bridge; thus, 24,000 lb. per square inch. (or 22,000) might be used for the dead load and for the ultimate future live load, taking for the latter a loading that might exist 30 or 40 years hence. If the live-load stresses were properly increased by impact addition, this method would give a balanced bridge. But, Professor Turneaure asked, is 24,000 a safe figure to place before engineers as the allowable unit for static loading? We now use 16,000. The committee did not feel that it could substitute 24,000 for this figure. And the same view held against accepting 22,000, or even 18,000, as an allowable dead-load unit-stress. The resulting conclusion is what the proposed specifications embody, namely, 16,000 lb. as dead-load tensile stress.

Unbalanced design is guarded against by a clause which requires web members to be designed for two-thirds dead-load stress plus 1⅓ of the live-load stress plus impact. A span of 200 ft. so proportioned will have webs and chords of uniform strength; a shorter span has the web system stronger, while a longer span has its chords stronger.

A special proviso limits the proposed specifications to spans not over 300 ft. long, as B. R. Leffler pointed out. Longer spans, in his opinion, are subjects of special design. Unbalancing is guarded against not only by the clause quoted by Professor Turneaure, but also by a clause which requires that in ballasted-floor bridges only three-fourths the floor weight shall be considered.

Other Work on Steel Structures

Specifications for movable bridges presented by the committee a year ago and printed in the *Proceedings* are still under advisement. Revision has been considered, but few comments or criticisms have been sent to the committee. A special request for such assistance was made at the meeting, in order to permit the carrying out of the revision this year.

No experimental work on impact and secondary stresses was done during the past year. The research is now regarded as concluded, and the subcommittee on the subject has been discharged. The conclusions already reached "are not likely to be modified by any further work of that kind which the committee might be able to do in the near future." Column testing, however, is to be continued, and steps have been taken to enlist the help of the Bureau of Standards, now that its war work is closed.

Plastic compounds for protecting structures of steel and concrete from the blast action of locomotive exhaust are being studied. Some experimental applications are under observation, but no report was made. Waterproofing is also to be worked on during the coming year.

Track-scale girder designs which had been prepared by the committee on yards and terminals were approved by the committee on iron and steel structures. They cover the design data and the girder sections for three sizes of track scale.

Improving the Quality of Concrete

Carrying forward his tests on excess water in mixing concrete, Prof. D. A. Abrams has obtained a large number of results confirming and supplementing his findings given in *Engineering News-Record* of May 2, 1918, p. 873. These additional results were presented by him in a paper forming an appendix to the report of the committee on masonry. Wear resistance, Professor Abrams found, is almost exactly proportional to strength. Both strength and wear resistance are greatly increased by limiting the amount of mixing water to a much lower point than common practice allows. Attention to the conditions of seasoning of the concrete is also important. Concrete made under favorable conditions as to consistency and curing showed an increase of 275% in compressive strength and 240% in wear resistance over concrete made under distinctly unfavorable conditions.

Prof. A. N. Talbot, in discussing this paper, gave a careful analysis of the factors correlating the moisture conditions, the mixing operation, and the strength of concrete. He called attention also to the effect of moisture on concrete that has been cured under insufficient supply of water. The later supply gives a great gain of strength. Some specimens in dry storage that were under observation and test for various ages showed at 7 years 3 months a strength of 3000 lb., but when thereupon placed in moist storage for 9 months they had a strength of 5000 lb. per square inch. However, while the supply of moisture during seasoning is vital, surface sprinkling may be ineffective and is often over-rated.

Discussing the time of mixing, B. R. Leffler stated it as his conclusion that the proper time for good mixture and adequate mobility of the concrete depends on the type of mixer. A time of 1 min. may be satisfactory for certain types of mixer, especially those of ½ cu.yd. and smaller, but not enough for others. From his experience, however, it is believed that many contractors are likely to protest strongly against a 1-min. mixing time.

Track Questions

Unsatisfactory relations between rails and wheels were indicated in the report of the track committee. The opinion was expressed that the present heavy wheel coning of 1 in 20 has disadvantages, and that the coning which gives minimum wear of wheels—which was the purpose of changing from 1 in 38 to the present 1 in 20—is not a condition favorable to economical wear and least stress of rails. Furthermore, a 1 in 20 canting of the rail is considered too steep an inclination, as it conforms to the present wheel coning and thus practically nullifies the objects aimed at in this coning.

Possible injury to rails by flat spots on wheels led the track committee to recommend that the present 2½ in. limit of length should be reduced to 1½ in. The impact effect increases with heavier and stiffer rails or with rigid, frozen roadbed. C. E. Lindsay, of the United States Railroad Administration, pointed out that the likelihood of damage by heavily loaded wheels having long flat spots is not generally realized. The recommendation was adopted and will be submitted to the Master Car Builders' Association with a request for the reduction of its present 2½-in. limit.

Cost of Curvature

A change in methods of valuating rail wear on curves was suggested by the committee on economics of railway location, in a statement to the effect that rail wear on curves, as compared with tangents, increases approximately as the square of the degree of curve. The importance of this was stated to be evident from the fact that heretofore it has been customary to estimate curve expense directly with the central angle, or with the degree of curve when a different length is considered. Individual experiences with rail wear on curves were brought out in the discussion.

Consolidation of the subgrade by a 10-ton roller to prevent water pockets in the roadbed was advocated by the roadway committee, which also suggested methods of curing such pockets by drainage and filling with porous material, while concrete filling for such pockets and wet spots was suggested by the ballast committee. Concrete-slab construction to carry the ballast was discussed by the latter committee, but it did not include the extensive experiments on the Northern Pacific Ry. which were described fully in *Engineering News-Record* of Dec. 12, 1918, p. 1071.

Screw Spikes

Screw spikes appear to be showing less favorable results than was anticipated a few years ago, when they began to be used to any large extent. Doubt as to their value in increasing the durability of ties was expressed by the tie committee, except under such special conditions as on elevated structures and in track having a more substantial foundation than the ordinary tie and ballast construction. It was explained by F. Boardman of the N. Y. Central R.R. that this statement was based on unfavorable reports from most of the roads using screw spikes.

As an offset to this statement, however, extended and favorable experience on the Delaware, Lackawanna & Western R.R. was recorded by G. J. Ray, formerly chief engineer. On a 30-mile stretch of double track laid in 1911 the only spikes which were loose after eight years' service were those in about 100 ties which proved to be rotten. A standard form of thread is important, as the replacement of one spike with another having a different pitch and form of thread will destroy the threaded groove in the wood, and after a few such replacements there will be no effective hold of the spike.

Expansion of the present allowable working stresses for structural timber to include treated timber is inadvisable without further experiments on treated and untreated timber in large sticks. This conclusion was presented by the committee on wooden bridges and trestles. Tests indicate that neither the character nor the quality of the preservative causes any appreciable decrease in the strength of timber, but that such effect is due entirely to the process of treatment and that this may affect different timbers in different degrees.

Zinc as an Alternative for Creosote in Treating Railway Ties

ZINC-CHLORIDE treatment for railway ties is justified where, for economic reasons, creosote oil is not available, or where conditions of maintenance will not warrant the expense of application of the latter. Furthermore, zinc treatment will secure at least double the life given by an untreated tie of the same kind in the same location, no matter whether oak or pine is used. In dry climates this increase in life may be still greater. These conclusions are given in the report presented by the wood-preservation committee at the annual meeting of the American Railway Engineering Association. The committee frankly says that creosote is the best timber preservative for all purposes, but points out economic limitations to its use.

Climatic conditions qualify the above conclusions favorably to zinc chloride, the Eastern and Southeastern states generally being excluded from the field for zinc-treated ties. Introduction of some lubricating agent with the zinc, to correspond with the action of creosote oil, is recommended where excessive rainfall and humid atmosphere would cause the zinc in the ties to be influenced unfavorably by leaching; also, where checking of the timber or its mechanical wear is likely to be excessive, but where it is not possible to secure a straight creosote treatment.

One of the objections urged against the use of zinc chloride has been that, as the salt is soluble, it will leach out of the wood by moisture and cannot be expected to give permanent protection. The committee finds, however, that leaching does not take place as rapidly as has been assumed. In ties which have been in the track for several years, especially in the drier climates, the zinc chloride has been found well distributed through the wood.

Air seasoning for 60 days after treatment is recommended, as it results in greater strength of the tie, increased resistance to wear by spikes and tie-plates, less leaching of the zinc, and less disturbance of signal circuits by leakage of current from the rails.

Progress in Study of Rail Quality

American Railway Engineering Association Research—Deep Etching of Longitudinal Sections of Rail Head Brings Out Network of Lines Present Before Rails Are Straightened—The Quick-Bend Test

EXTENSIVE studies of rail quality made during the past year under the direction of the Rail Committee of the American Railway Engineering Association led to results that represent marked progress and give a distinctly better understanding of rail troubles. An important factor in the matter was that, due to the increasing interest in the subject on the part of the railroads, more investigators worked on the problem than ever before, according to a statement by P. H. Dudley of the New York Central Lines. "This is due," says Dr. Dudley, "to so many officials of the railroads having found from the service records that some brands of rails in the track had a large number of failures, while other brands rolled under a different mill practice did not have one failure in the same section, though subject to the same wheel loads and tonnage."

Three prominent points of the new research work are: (1) The discovery of the value of deep etching with strong acid to bring out hitherto unrecognized defects in the interior of the rail head; and the discovery through such etching that defective rails show a startling degree of non-homogeneity, streaks running in various directions through the rails; (2) statistical proof that rolling rails direct from the ingot contributes to the production of transverse fissures in the rail; rolling from reheated blooms is a preventive; (3) study of a new toughness test for rails, a bending test in a hydraulic press, as a substitute for the drop test, long the traditional standard of rail acceptance testing.

Depp Etching Brings Out Extensive Flaws

F. M. Waring, engineer of tests at the Altoona laboratory of the Pennsylvania R.R., last summer developed the use of deep etching with strong mineral acid to bring out defects in longitudinal sections of rail heads. This laboratory and the rail officials of the Pennsylvania system have for a number of years centered their attention on non-homogeneity of rail metal as a responsible cause of rail failures, and in this line of thought some years ago decided that chemical analyses of samples from different parts of the cross-section of the rail must not show large variations of composition, if the rail is to be regarded as satisfactory. Pursuing the same line of thought, laboratory studies were made to discover indications of unsoundness, by etching longitudinal horizontal slices cut from the heads of rails and carefully smoothed and polished. The usual micrographic etching solutions did not bring out any special appearance, although this method in some prior cases had revealed hair cracks in the metal. It was then decided to use a more drastic etching process. Trial was made of successive etchings in a number of the solutions, still without result. But very definite results were attained when the specimens were etched for two hours in hot, strong, mineral acid (nine parts of hydrochloric acid, three parts sulphuric acid, and one part of water, kept at 200° F.). This brought out a remarkable number of longitudinal, transverse and irregular marks or depressions. These marks, representing streaks of more soluble material, proved the existence of serious non-homogeneity, likely to lead to irregular stress distribution in the rail and therefore create opportunities favorable to cracking in service.

These deep-etching studies were applied to a number of rails that had developed transverse fissures in the track (or in some cases while being tested), and the same irregular markings were found in nearly all cases. On the other hand, a rail that performed well under the drop test, though made from the same heat of steel as a number of the defective rails, showed uniform metal when etched by this method. Mr. Waring in a report to the railroad company says, "Since these rails were all from one heat, of a fairly uniform chemical composition, and rolled at the same time, and since they were all subjected to approximately the same amount of service in the track, it would appear as if these defects found in the rail heads are associated in some manner with the process of manufacture."

Trial was then made to see whether similar defects could be found in a rail that had never been in service. The deep etching with mineral acid brought out the markings, though picric acid etching had failed to develop anything unusual.

"An examination of all these deep etchings," says Mr. Waring, "brings out the fact that these small internal transverse ruptures correspond in their location and appearance with the nuclei of transverse fissures, and it is possible that they may be the original cause of such fissures."

Closely related to this investigation is an observation made by J. B. Young, chemist of the Philadelphia & Reading R.R., a few months ago. Test specimens cut from the center of the head of a 100-lb. rail that had never been in track, and had not even been on the hot bed, showed cracks in various directions through the metal. The cracks were noticed after the standard test specimen was fractured in the testing machine. Hitherto, many rail experts have believed that small cracks are produced in the rail head during the straightening process, in the gag press, but in the present case there had been no gagging or other straightening. Mr. Young therefore holds that his findings "are conclusive evidence that flaws and cracks exist in new rails which have been subjected to no strains except those developed in the rolling."

Reheated Blooms Make Good Rails

Reporting on the subject of transverse fissures, Dr. P. H. Dudley, consulting engineer, New York Central Lines, brings sharply into view various discrepancies of fact that have surrounded the two opposing theories on the cause of transverse fissures. As against the theory of James E. Howard that repeated stresses in track service produce the transverse fissures (as fatigue fractures), Dr. Dudley directs attention to the fact that the nucleus is not a point but is of measurable size, and, from its appearance, obviously resulted from a process different from that of the rest of the area. He emphasizes the fact that such fissures occur only in an occasional rail head, although design, traffic conditions, and stresses are alike for many rails, and there-

fore, if stress is the cause of the fracture, most rails should break in the same way.

That transverse fissures in their development are fatigue or detail fractures is conceded by Dr. Dudley: "There is no difference of opinion about the growth in the track of the specular surfaces which start from and around the nuclei of interior transverse fissures." What fault or flaw at the nucleus gives opportunity for the transverse fissure to start remains the essential problem. Dr. Dudley refers to the discoveries of Mr. Waring and Mr. Young, above mentioned and to the discovery of streaks of high-phosphorus metal in defective rails by George F. Comstock, as reported in *Engineering News-Record* of Mar. 13, 1919, p. 532. Without expressing an opinion on these discoveries, however, he brings out other facts on the influence of reheating the steel before rolling.

Statistics prove, Dr. Dudley shows, that about all transverse fissures occur in rails rolled direct from the ingot, while rails from reheated blooms virtually never fail in this way. This appears to establish beyond question that qualities or defects of the steel are responsible, rather than excessive stress.

The service records of eight railroads for the seven years 1909-1915 exhibit a total of 559,644 tons of rail produced by direct rolling; in these rails 1054 transverse fissures developed. The same road had 322,593 tons of rail made from reheated blooms, and these developed only 59 transverse fissures, or less than one-tenth as many per ton of rail as by the direct-rolled material. The rails were rolled at 11 mills, and thus represent a large variety of mill conditions. Moreover, 27 of the 59 failures of rails made from reheated blooms came from a single mill, and are said to have been rolled at a time before the mill practice was made uniform and good. It should be mentioned that the whole group of statistics concerns only heavy rails; that is, rail weighing 100, 101 and 105 lb. per yard.

Whether finishing the process of rolling the rail at a low temperature is advantageous was also studied by Dr. Dudley. Some years ago it was a common charge that steel rails were put through their finishing passes too hot, and thus did not go through the grain-refining process which cooler rolling would have brought about. Dr. Dudley cities experiences showing that a low temperature in the last pass of the rail mill is apt to produce brittleness. This brittle metal is capable of being restored to a tough condition by annealing. General experience leads him to conclude that chemical composition has an important influence on toughness or brittleness, and he concludes that steel with more than 0.85% carbon is particularly likely to have its toughness destroyed in the rolling or in the cooling of the rails on the hot beds with the effect of producing brittleness.

Surveys of rails by a magnetic tester to detect internal flaws were made by Dr. Dudley recently. He gives no detail results, but states that the leakage curves of rails obtained with this apparatus furnish much information about the physical properties in rails and about the disturbance of the metal by the gag press used in straightening it.

Rails are tested for acceptance by the Pennsylvania R.R. by means of a press bending test in addition to the regular drop test. The press is in a hydraulic machine operated by an intensifier standing alongside, and capable of exerting a pressure of 378 tons. The main ram is 16 in. in diameter and has a 12-in. stroke. The machine weighs 11 tons. The supports for the rail, under the press ram, may be set at various spacings; tests have been made with supports 24 to 51 in. apart. A hydraulic pressure indicator records on a drum turned by a connection with the main ram, so that an autographic diagram is produced.

Deflections at ultimate load of rail specimens bent in this machine are found to be an indication of the ductility of the material, just as well as is the elongation in the drop test of the rail. It is also belived that the deflection is in a measure an indication of the toughness of the rail, or rather its capacity to resist shock.

Tests made with the head down (in tension) gave more satisfactory and uniform results than those made with the head up. In the former, breaks were obtained in nearly all cases, while with the head up the breaks were apt to be branching or irregular. Furthermore, the tests made with different lengths of span of the rail showed closer agreement between the test results and theoretical curves, for the tests with head down than those with head up.

One of the striking results of tests with the bending machine brought out in a report on the subject submitted by W. C. Cushing, chairman of the subcommittee on the quick bend tests, is the distinct superiority in quality of the rails produced by one mill as compared with those of another. A large number of tests of 130-lb. rails from three mills, plotted to show elastic limit as ordinates and ultimate deflection as abscissas, placed the rails from one of the three mills in a group distinctly above and to the right of the groups representing the other two mills. This comparison shows greater ductility and strength, on the average, for the rails of the first mill, though all were rolled to the same specification and the same section and weight.

In another experiment, a rail that failed in the bend test at a small deflection—in other words, was brittle—was retested after annealing, and the deflection was increased more than four times, indicating a curing of the brittleness by the heat treatment.

Rail-Joint Tests Show Heat Treatment and Short Bars Advisable

THAT plain angle bars, if heat treated, can make a rail joint having strength and efficiency equal to that of the solid rail, is the important conclusion of a report submitted by the rail committee of the American Railway Engineering Association as an appendix to its own report. This rail-joint report was made in 1915 by C. D. Young, then engineer of tests of the Pennsylvania R.R. It was based on tests made at the Altoona laboratory covering different forms of plain angle bars, splice bars with stiffening flanges depending below the rail and joints giving a base support to the rail.

Heat-treatment results constitute the main feature of the report, showing an increase in elastic limit ranging from 60% in solid 100-lb. rail to 79% and 150% in plain angle-bar joints with six and four bolt holes, respectively. In the rail the elastic limit was raised from 175,000 to 280,000 lb., while in the bars it was raised from 70,000 and 50,000 lb. to 125,000 lb. in both cases. From this the conclusion was drawn that heat treatment was one of the simplest and most economical means of increasing the efficiency of the joint.

The treatment mentioned consisted in heating the material above the recalescence point (approximately 1500° F.), quenching in water, and then annealing the hardened steel at about 1050° F. It was estimated at that time (1915) that this should not add more than $5 to the cost of the steel, while it would increase the stiffness of the bar at least 50% and still leave the metal softer than the rail.

Mr. Young pointed out that a joint equal in efficiency to the solid rail could be obtained by heat treatment of some of the patented types of joint, or at less cost by similar treatment of a special angle bar. The joint with this bar showed a strength, at the elastic limit, equal to the rail, and would cost less than the then standard angle bar, which had a strength about 33% that of the rail. The new bar was to be used with heat-treated bolts, as, being shorter than the standard bar, it might require greater bolt strength.

Comparison of joints having four and six bolts indicated that the two additional bolts gave no increase in strength in transverse loading. It was concluded that a four-hole splice is sufficient for 100-lb. rail if it is of proper section and material. It has fewer parts and greater cross-sectional area for the same weight. As to bars 26½ in. and 18½ in. long, tests with 20-in. and 26-in. spacing of supports indicated no loss of efficiency in the joint having the shorter bars.

Switching Cars Into Station Order at Large Freight Yards

METHODS of sorting cars or switching them into station order for outbound trains are discussed briefly in the report presented by the committee on yards and terminals at the annual meeting of the American Railway Engineering Association. Suggestion has been made for the provision of a small gravity yard for this purpose, located between the classification and departure yards, but the committee finds that such an arrangement is rarely provided or, at least, rarely included in yard construction. In some gravity classification yards, such sorting is accomplished by means of a yard tributary to the hump, having its ladder next to the outside track of the main yard and its short body tracks diagonal to this. The same purpose might be effected by intermediate ladder tracks subdividing a few of the main classification tracks at one side of the yard.

In the opinion of the committee, secondary sorting of cars for station order or other similar grouping can be accomplished satisfactorily by supplementing the gravity switching for classification with flat switching by engines at the foot of the hump yard or in the departure yard. This would save the additional investment and increased length of terminal involved by an auxiliary sorting yard, and it would avoid the delay attending the delivery and removal of cars at such a yard.

In certain situations, however, the auxiliary yard may be necessary, as where it is impossible to provide a sufficient number of tracks in the classification yard, or where the number of cars to be handled is too great to permit of switching them at the outgoing end of the classification yard or in the departure yard without hampering the flow of traffic. It should have assisting grades if practicable, and the length of its tracks would be governed by the requirements of each case.

Railroad Engineers' Conference Adopts Wage Scale

Representatives of Fifty Roads Meet—Chief Discussion on Pay of Chief Engineer, Division Engineer and Tapeman

(*Editorial Correspondence*)

FOR the first time in the history of engineering a body of 350 engineers, representing fifty railroads, met in Chicago Mar. 17 to discuss openly and above board a minimum salary schedule for every technical position from chief engineer to tapeman. No unusual demonstration preceded this history-making meeting, only the usual setting of a well planned, well carried out convention of engineers who always take their society gatherings seriously. Born of experience gained by years of handling the intricate problems on the greatest transportation systems of the world, the men proceeded to business with reference to their own economic welfare in somewhat the same manner as has been the custom in getting practice and procedure ironed out in the American Railway Engineering Association. In railroad parlance, it might be said that the schedule was adopted as "recommended practice," but was not ready to be "incorporated in the 'Manual.'"

The program, carried out by the American Association of Engineers, was well planned. The chairman was one who all felt had given justice to young as well as old engineers. Willard Beahan is a white-haired engineer, revered by hundreds whom he has fathered into real usefulness from the time of his experiences with General Dodge, finding the line for the Union Pacific (fighting Indians meanwhile), down to his present capacity of assistant chief engineer with the New York Central.

Leading up to the main business of the meeting, which was the discussion of a "preliminary report by a subcommittee of the railroad committee," of the American Association of Engineers, was a paper on overtime by H. P. Gillette, editor of *Engineering and Contracting*, which laid down a rough rule that when the salary reached $200 a month, or when the duties became advisory, overtime allowance was not desirable. A sufficient number participated in the discussion to break the ice of acquaintance. A venerable Seaboard Air Line engineer came to mental grips with a young division engineer from the Southern Pacific. A middle-aged chief draftsman from the Missouri Pacific let the audience know that the Middle West had similar difficulties.

Discussion of Schedule

Well acquainted now, the engineers were plunged into the intricate problem of classification and salary-fixing by J. L. Jacobs, a specialist on system and organization. With his word for it that a world of work lay ahead of them in gathering statistics, standardizing positions and nomenclature, the conference was in a proper frame of mind to appraise the work of the subcommittee, a work which the Wage Board in Washington gave up in despair. W. C. Bolin, chairman, explained that the subcommittee had been at work night and day for two weeks on the problem after the paid staff of the committee had gathered a mass of information from all over the country as to existing schedules, in and out of the profession. Three elements of the schedule—the salaries of chief engineer, division engineer and tapeman—were attacked first, for, said Mr.

Bolin, with these points fixed the determination of the intermediate salaries became a matter of mathematics tempered by good judgment. Reasons for every piont were forthcoming immediately from Mr. Bolin. No question seemed to have been without consideration, and so well had he and his co-workers hit the consensus of opinion that only six salaries proposed, out of 36, were revised. A surprising unanimity of opinion was found as to nomenclature and definition. Only one position, that of assistant electrical engineer, was added, and only one name changed, that of detailer to junior draftsman.

With the schedule adopted, the conference was not ended, for still, holding to engineering procedure, the next step was a set of specifications for the plans, a paper by W. W. K. Sparrow, corporate chief engineer of the Chicago, Milwaukee & St. Paul, on "How Shall Proper Recognition Be Obtained?" Walking still on crutches from a recent accident, dramatically he called on engineers inside and outside of railway service to unite for proper concerted action all engineering societies of the country into a United Engineering Society of America. But Mr. Sparrow is not an impractical dreamer, and, until the constitution of a league of societies has been drawn—which, he well said, should not be so hard to frame as that for a league of nations—he proposed to support the organization which had fathered the conference and to urge every engineer of his acquaintance to do likewise. And when, in answering the question of a skeptic as to what he would do should the railroads refuse to consider the schedule proposed, he said, "I would not strike," the spontaneity of the applause said louder than words, "We are not that kind of an organization." "But," said Mr. Sparrow, "after the lessons of the war I believe men will get what, in justice, they are entitled to get." Organization for the purpose of giving the profession a single voice with authority back of it, licensing to give political and social status, and a broader education, with interest and activity in other than purely technical matters, were his suggestions for obtaining greater recognition.

The committee's next step is the presentation of the schedule to the Wage Board in Washington, for it is the opinion of many that that body will not refuse to reopen the hearings of February, 1918, to listen to the united voice of the railroads' most valuable and trusted class of employee.

SCHEDULE OF MINIMUM SALARIES ADOPTED BY RAILROAD CONFERENCE OF AMERICAN ASSOCIATION OF ENGINEERS

The duties of resident engineers involve construction work of ordinary magnitude. Where exceptional work is undertaken it is assumed that the assistant district engineer, district engineer or assistant chief engineer will take charge personally.

The duties and qualifications attached to the positions named are generally well understood. Any schedule of rates promulgated should specify that the work actually performed should govern. Thus, if a railroad calls a man an assistant engineer and he is actually performing the usual duties of a division engineer or other position, he should receive the pay of that position.

The rates for the higher positions do not apply to short lines, terminal railroads and roads of similar character, the rates in these cases to be in proportion to the duties and responsibilities assumed, based upon the schedule.

The schedule is not to operate to reduce any salaries now existing.

Expenses away from headquarters or in connection with moving headquarters are to be allowed.

No pay is to be allowed for overtime.

Civil service rules are to apply as to annual and sick leave.

The following schedule of salaries is adopted:

Chief engineer	$15,000 to $9000
Assistant chief engineer	9000 to 7200
District engineer	6000 to 4800
Assistant district engineer	5400 to 4200
Division engineer	4800 to 4200
Assistant division engineer	3600 to 3000
Resident engineer	4200 to 3000
Office engineer—field engineer	5400 to 3600
Engineer of bridges	7500 to 6000
Assistant engineer of bridges	5400 to 4800
Signal engineer	7200 to 4200
Assistant signal engineer	4800 to 3000
Building engineer	6000 to 3000
Valuation engineer	8400 to 7200
Assistant valuation engineer	6000 to 4800
Chief pilot engineer	4800 to 3600
Pilot engineer	3600 to 3000
Engineer accountant	4800 to 3000
General superintendent of motive power	15,000 to 9000
Assistant general superintendent of motive power	9000 to 7200
Mechanical engineer	7500 to 6000
Assistant mechanical engineer	4800 to 3600
Engineer of tests	7500 to 6000
Electrical engineer	8000 to 6000
Assistant electrical engineer	4800 to 3000
District electrical engineer	3600 to 2700
Shop engineer	4800 to 3600
Chief draftsman	3600 to 3000
Leading draftsman or designer*	200 to 250
Draftsman*	150 to 200
Junior draftsman*	125 to 150
Tracer*	100 to 120
Engineer inspector*	150 to 225
Instrument man*	200 to 225
Rodman*	125 to 150
Tapeman*	100 to 120

*Rates per month stated for junior positions cover the length of service in the respective positions, an increase of not less than $5 for each six months' service to be granted up to the maximum rate of the position.

Without the efforts of the American Association of Engineers, in bringing the conference together, in financing the machinery necessary to gather the data on which the schedule is based and in energizing individuals to action, the movement could not have been consummated. On that organization still remains the burden of opening the way to the Wage Board and of keeping the schedule up to date as conditions change. It may rest assured that support will be forthcoming from the railway engineers. W. W. D.

Machines Cut Water-Main Costs in Detroit

Shortage of labor and high wages have been largely counterbalanced by the Board of Water Commissioners of Detroit, Mich., by extensive use of machinery in laying water mains. Mechanical appliances are now used nearly exclusively for trench excavation, backfilling, tamping and pavement cutting, pumping and pipe handling. The savings per foot effected by machines in constructing pipe lines of smaller sizes are given as follows:

Size of Pipe	Hand	Machine	Saving
6	$0.59	$0.35	$0.24
8	0.58	0.40	0.18
12	1.11	0.49	0.62
16	1.62	0.99	0.63

Labor per foot in laying 42-in. and 48-in. pipe will average $8.70 by hand, and $3.50 by machinery; calking averages $1.32 per joint by hand, and $0.49 using pneumatic hammers; handling and lowering each pipe by hand labor averages $6.70, and $1.88 using the steam crane. Backfilling ditches on small lines costs about 9c. per lineal foot by hand and 3½c. per foot by machine.

Additional Meteorological Data Needed by Engineers

Points on Which More Data or Further Study Would Be Helpful, Including Rainfall Distribution and Intensity, Precipitation and Heavy Floods, Evaporation, Vegetation, Soil Infiltration, Temperature, Run-off

By Robert E. Horton
Consulting Hydraulic Engineer, Albany, N. Y.

EVERY experienced hydraulic engineer feels the need of additional meteorological data. First of all, there are far too few rainfall stations, and where the stations are reasonably close together group records should be studied to gain light for use where the stations are far apart. Periodic distribution of precipitation, rainfall intensities, flood flows, evaporation, the influence of vegetation, soil percolation, temperatures of the air and of the surfaces of both soil and water, and, finally, the broad general phases of run-off—all need attention. A brief review of the more important meteorological needs, grouped under 10 heads, follows:

1. More Stations—A much larger number of rainfall stations is needed throughout the country generally. In the East there is generally one station in each county, an average of about one station to every 1500 square miles. In England, Denmark, Saxony, Jamaica, Barbados, St. Kitts, Victoria and Mauritius there is an average of about one station to every 40 square miles. That is sufficient to provide good data for almost any small drainage basin, such as is commonly required for gravity water-supply systems. In New England the number of rainfall records available is about twice as great as elsewhere in the United States, owing to the fact that many good records are maintained in conjunction with water-works systems. But even in New England the number of stations is by no means adequate for satisfactory determination of the rainfall on many small drainage basins used for gravity water-supply.

2. Special Group Studies—In view of the sparsity of rainfall records, special groups of stations are needed, and studies based on existing data to determine the reliability, both of the long-term mean for any one station and the actual annual and monthly amounts indicated by single gages when applied over a varying radius of 1, 5, 10 or 15 miles from the station. Data are available at Providence, Worcester, Pawtucket, St. Louis and New Orleans, where rain gages are maintained sufficient in number to determine the general accuracy of a single record as applied to larger or smaller surrounding areas in those particular localities. Undoubtedly, with more data general relations could be established which would greatly increase the utility of rainfall records, and would also increase the degree of confidence which could be placed in such records where it becomes necessary to apply a single station to a considerable area.

3. Periodic Distribution of Rainfall—Experience shows that with identically the same rainfall distributed in different ways throughout the year, especially during the summer, quite different amounts of run-off may result. In applying rainfall data, in critical cases, it is, therefore, necessary to take into account its distribution as well as its total amount. It is desirable, therefore, that the total number of rainfall days per month at each station should be published, with the amount of rainfall. For example: A rainfall of 4 in. in August may all occur in four days, with heavy thunderstorms, or it may be distributed throughout 10 or 20 days. In the latter case, the opportunity for water loss by evaporation would be enormously increased by the long continued wetting of the ground surface, and the available supply for run-off would be steadier, but much smaller in amount than in the case of concentrated rainfall. I believe that practical methods can be readily developed by which the effect of rainfall distribution can be taken into account in estimating stream yield, if the number of rainfall days is known.

4. Intensities—As regards rain intensity, there are at present about 200 stations in the United States with recording rain gages. The details of these records, some of them running back to 1896, are published in the *Monthly Weather Review* and in the annual reports of the Chief of the United States Weather Bureau. No complete, exhaustive analyses of all these records have ever been made. Partial analyses, covering the records within considerable areas, or for a considerable number of stations, have recently been made by Meyer and published in his "Elements of Hydrology," and by the United States Housing Corporation, the results not yet having been published. So far as the results go, they indicate that rain intensity formulas of the same type, but with varying coefficients, can be applied to localities having widely different amounts of rainfall.

Room for Much Valuable Work

Practice hitherto in using rain intensity data in storm-sewer designing has been in general to work out a rain-intensity curve for each different place or problem. Usually, the data of the most intense and most critical storms are meager, and the results of such scattered individual studies are unquestionably less reliable than would be those obtained by thorough, general analyses involving a large number of stations of smaller rainfall characteristics. There is room for much valuable work in standardizing and analyzing rain-intensity data along more general lines. Not only this, but all attempts hitherto to utilize such data have been wholly empirical. There is reason to believe that at least a semirational formula of general application can be developed for rain intensities of short durations.

5. Great Storms and Floods—In connection with the broader problems of flood causation and flood discharge, studies of rain intensity in great storms covering periods of one to five days are needed. A valuable start was made in this direction by the Miami Conservancy District, the results being given in its series of technical reports, Part 5. Good work along similar lines, with much more numerous records on which to base the results, has been done by the British Rainfall Organization.

One of the most fundamental problems of flood control is the determination of the relative frequency of

occurrence of floods of different magnitudes, as fixing the maximum size and cost of works economically justified for flood control. Further data and analyses along these lines are much needed, and would be likely to afford results of broad utility and permanent value.

It may be noted in passing that so far as the studies by the Miami Conservancy District go, they seem to indicate that the law covering the relative magnitudes of storms of one to five days' duration, and having different intensities and frequencies of occurrence, is very similar in form to the general law covering the relations between frequency, intensity and duration of short storms, such as are involved in storm-sewer designing—with, however, probably, the important difference that temporary storage of considerable volumes of rain by suspension in the upper air, in ascending air currents, is the important factor contributing to high intensities for rainfall duration of less than, say, one hour, but is not of importance in relation to storms of one or more days' duration.

Incidentally, there is a gap between existing results of studies covering, on the one hand, rain intensities used in storm-sewer designing and of generally less than one hour's duration, and flood intensities of one or more days' duration. This seems to open up a profitable field for investigation—a field which would be very likely to lead to results useful in both classes of studies. Furthermore, in many flood problems and in numerous litigations involving rainfall, the only data available are daily rainfall records. Data and studies showing the relation between 24 hours' rain and the average duration and intensity for the actual portion of the day during which rain fell are much needed.

6. *Evaporation*—With regard to evaporation, very good records are now being kept by the Weather Bureau and other Government organizations. It appears, however, that records obtained from the ordinary evaporation pan, say 3 ft. square, are not directly applicable to broad water surfaces. There is need for experimental determination of what may be called the area factor or average ratio of evaporation loss from a standard pan of a certain size to the evaporation loss from an area of any given size larger or smaller. A start along this line has been made in the work of Prof. F. H. Bigelow, R. B. Sleight and others.

Altitude and Evaporation

The writer, in *Engineering News-Record* of Apr. 26, 1917, p. 196, has called attention to the physical factors underlying and controlling this so-called area factor. The area factor involves, however, certain climatic conditions, especially convective action, data for which are not included in meteorological reports. In view of the complexity of the subject, further studies, especially out-of-door experiments with evaporation pans of various sizes, are greatly needed.

In this connection, too, attention may be called to the need of further data and studies on the relation of altitude to evaporation. There is a prevailing popular notion that evaporation increases with elevation. This idea is undoubtedly derived from the well known fact that water boils more readily at high than at low altitudes. This, however, is only one of the elements involved. Mean temperature at the surface decreases on the average about 1° for 300 ft. elevation. The absolute humidity also decreases with elevation, in accordance with the exponential law developed by Hann. Wind velocity generally tends to increase with increased elevation. The amount of evaporation from water surfaces is mainly controlled by temperature, humidity and wind velocity, and is affected probably to a minor extent by other factors, including so-called radiation or black-bulb thermometer temperatures, facility for convection, and barometric pressure. Some of the factors tend to cause an increase, and others tend to cause a decrease in the amount of evaporation, with increasing altitudes. The natural result would be the occurrence of some particular elevation for which evaporation losses would be maximum. While this fact never seems to have been pointed out before, yet it is confirmed by the few good observations available, especially those of Charles H. Lee. The whole subject of relation of evaporation loss to elevation is worthy of further investigation and more rational discussion.

7. *Vegetation*—The subject of interception of rainfall by vegetation will be seen to be one of great importance, when it is considered that oftentimes, especially in light showers, 50% or more of the rain is caught upon and directly evaporated from trees or other vegetation and never reaches the ground. This subject has been experimented upon in Europe, and to a limited extent in the United States by the writer, and, I believe, also by the United States Weather Bureau. Further investigation and discussion would aid in laying a foundation for more rational estimates of stream flow and better determinations of water requirements for irrigation purposes.

8. *Infiltration*—Floods are mainly the results of direct surface run-off from heavy rains or melting snows. The direct evaporation loss during flood rains is usually only a very small proportion of the available supply of water. The difference in flood-discharging capacities of different drainage areas is, without doubt, more largely due to differences in the amount of water which can percolate into the soil during heavy rains than to any other one factor excepting rainfall itself.

Soil Infiltration During Rains

Furthermore, infiltration of rainfall is the source of ground-water supply to streams, wells and artesian horizons; yet, with the exception of some meager experiments by O'Meara and the writer, practically nothing has been done in this country relative to the determination of the amount of infiltration into different soils, on different slopes and with different rates of rainfall. Numerous formulas for estimating maximum flood discharges have been evolved, but it does not seem possible to arrive at either a rational understanding of the causation of floods or the most reliable method of estimating probable maximum flood discharge without taking into account the amount of infiltration occurring during rains.

9. *Temperature*—The most important factor affecting evaporation losses of all kinds is temperature. It is also an important factor in relation to floods as affecting the rate of melting of accumulated snow. Data for air temperature are generally available, but what is needed in relation to evaporation is the temperature of the soil and of water surfaces. Data on these subjects are meager. The obtaining and publishing of additional data of soil-surface and water-surface temperatures, and especially the correlation of such temperatures with air temperature, are matters which will become of increasing importance and value as the

development and use of more rational methods of handling hydrologic problems progress.

10. Run-off—The run-off or yield of a drainage basin is the difference between the precipitation on the drainage basin and the water losses due to evaporation of various kinds. The amount of evaporation from the soil surface is dependent upon the same factors which control evaporation from water surface and, in addition, it is dependent on the degree of saturation of the soil surface. Some experimental data in relation to the evaporation loss from soil surface with different degrees of saturation have been obtained by Samuel Fortier (see *Engineering Record* of Apr. 15, 1905, p. 430).

Additional experimental data along this line would be of the utmost practical and economic value, not only in relation to the ordinary problems of hydrology in estimating stream flow, but also in relation to irrigation, land drainage and agricultural engineering in general. The writer has designated the ratio of the actual evaporation rate from a soil surface at any given time and with any degree of saturation to the evaporation rate from water or a saturated soil surface as the "evaporation opportunity."

It so happens that in long periods of drought, when the evaporation rate from a saturated surface is highest, the evaporation opportunity from the soil surface decreases. It is a natural result of these opposing influences that there is some particular amount and distribution of rainfall in any locality for which the total evaporation loss from the soil is a maximum. Although this is important, the writer does not think that it has ever hitherto been pointed out. Strangely enough, it follows as a simple mathematical deduction from a number of existing formulas for calculating run-off and, furthermore, it is abundantly confirmed by experience, inasmuch as it will be found that if almost any long-term record of rainfall and stream flow is analyzed, and the results are plotted in terms of water losses against precipitation, the resulting water losses will have a maximum for an annual rainfall which generally lies between 45 and 75 in. in England and the Eastern United States.

This calls attention to the fact that the older ideas and methods of expressing run-off as a percentage of rainfall are essentially fallacious, and if engineers are to justify public confidence with regard to their ability to predict safely the available yield of water-supplies, their work must, in the future, be founded upon the use of meteorologic data now often ignored and upon more rational and detailed methods of analyzing and utilizing such data.

Licensing Laws in Oregon and Idaho—Proposed Ohio Bill

Unique Features in Ohio and Idaho Bills—Oregon Law Follows Joint Committee—Iowa's Proposed Law

PROGRESS in the movement to license engineers is seen in the fact that the Association of Ohio Technical Societies has prepared for introduction into the legislature of Ohio a bill which contains many unique features. It is designed to include all classes of professional engineers and architects; also land surveyors, by specific provision. The special features of this bill are here presented, and a short statement follows giving the features in which the bill passed by the Oregon legislature Feb. 26, 1919, differs from the Joint Committee bill, as discussed in *Engineering News-Record* of Feb. 27, 1919, p. 423. A similar bill has just been introduced into the Iowa legislature. The Idaho legislature has just passed a licensing bill, the main features of which are here given.

The Ohio bill provides for a state board to be appointed by the Governor "by and with the consent of the Senate," for the purpose of registration for professional engineers and architects. It is to consist of nine members, not more than five of the same political party, and with one representative each for civil, mining, mechanical, electrical, and chemical engineering, and architecture. The qualifications for membership include a five-year previous residence and 10 years of active practice; the latter may be in teaching the profession, but not more than three members may be appointed who have had such active practice in teaching professional engineering in a reputable college or university. The secretary of the board may or may not be a member, but must have the qualifications of a member, receives a salary to be fixed by the board, and must give a bond. Members of the board receive no compensation except necessary expenses. The board shall meet in Columbus on the last Wednesday of June each year and at other appointed times. Seven members constitute a quorum.

The bill provides that after one year from its passage it shall be unlawful "for any person to practice professional engineering or architecture, as defined in this act, or to hold public office or employment involving the practice of such professions, or to set or disturb boundary monuments in Ohio, unless such person shall have first obtained a certificate entitling him to practice professional engineering or architecture from the board. Such certificate shall state whether the holder thereof is registered as a professional engineer or architect."

Special provisions are made for registering surveyors. No map or plat of any land or mine shall be accepted unless certified by a registered professional engineer or a registered surveyor. The act shall not apply to officers holding office or officers-elect at the time of passage of the act, during the term for which they have been elected, or to engineers or architects in the employ of the United States Government, but the latter shall not do any engineering or architectural work in Ohio except that pertaining to their official position, unless they comply with the act. Registered professional engineers or architects only can qualify to give testimony as engineering or architectural experts.

Definition of Professional Engineering and Architecture—These are defined to include all branches other than military engineering, as follows: "Any person who designs *or makes drawings for* any building, bridge, railroad, harbor, water-works . . . " etc., including a complete list of possible activities for all classes of engineers, not even excepting marine architecture and landscape engineering. It includes a person acting "as resident engineer, department engineer, division engineer, assistant engineer, clerk of works, or other similar title, with authority to exercise discretion, assume responsibility, devise methods, or to perform duties ordinarily delegated to such position . . . "even though employed by or under the di-

rection of a registered professional engineer or architect. However, nothing in the act is to be construed to prevent the employment of assistants of grades below those specified "provided they are under, and report directly to, registered professional engineers or architects or a registered surveyor, who assumes all responsibility for their work." Residents outside of Ohio may be called to testify as witnesses without holding certificates.

Qualifications for Certificates—A certificate may be issued to any applicant holding lawfully a diploma in any branch of engineering or architecture, except surveying, from a college or university approved by the board, together with evidence that he has had at least two years' practical experience; or to any member in good standing in the six great national engineering societies (including the Chemical Engineers and Architects) or other national engineering organizations having similar requirements for membership; or who, within one year, submits evidence of five consecutive years' prior practice; or to any applicant who successfully passes an examination before the board, to determine his fitness for such practice. The board may grant a certificate to practice land or mine surveying to any person otherwise eligible under the foregoing requirements, whose practice has been limited to such branch, or who, upon examination, satisfies the board of his fitness to practice the same; but the holder shall not be entitled to practice any other branches except surveying and platting of land or mines.

In providing for nonresident engineers, architects or surveyors, certificates are granted to those from such states as have equal qualifications, provided equal rights are accorded by such states to Ohio registered engineers, architects or surveyors. The fee is the same as that in the state from which the engineer comes; or if there be no such fee, it is made $10.

The board may reject an applicant guilty of fraudulent methods of practice, or revoke a certificate for the same cause. An affirmative vote of not less than six members shall be required to authorize the issue or revocation of a certificate. The fee for consideration of an application is $10, without examination, and for examination the fee shall be $25; for certified copies of certificates, $1 per copy. In no case shall the fee be returned in event of refusal to grant a certificate, but unsuccessful candidates may be examined at any subsequent session within one year. Fraud in obtaining a certificate is made a misdemeanor, punished by a fine not exceeding $1000 nor less than $100, or imprisonment of not more than one year nor less than 30 days, or both. Violation is classed as a misdemeanor, punishable by a fine of not less than $20 nor more than $500, or imprisonment of not less than 30 days nor more than one year, or both. The secretary of the board is charged with the duty of enforcing the act.

Bill Passed by Oregon

The bill just passed by the Oregon legislature is almost exactly like that of the Joint Committee proposed in 1915, but with modifications stated below. It takes effect on July 1, 1919, when the term of office of the Board of Examiners also begins. It prescribes Jan. 1, 1920, as the date after which certificates must be obtained to allow practice.

The prohibition against permission to testify is omitted; the salary of the secretary of the board is specified at $1200 per annum; his bond is to be fixed by the board; the fees are to be paid into a special fund, the "Engineers' Registration Fund"; the fee for admission to examination is $10, the additional fee for certificate is $5; and $15 is required for a certificate without examination for which six years, instead of ten years, of practice are required, not necessarily immediately preceding the date of application; penalties for violation are provided by a fine of from $25 to $500, or imprisonment not to exceed six months.

The act does not apply to "any architect practicing architecture," and the time limit for engineers from without the state is placed at three months before application for examination must be made, and the following clause is added, "The service of professional engineers in the United States military service shall be considered as the practice of professional engineering, and provided further that such Army engineers may be registered without examination . . . within a period of one year from the date of their discharge." No provision is made by appropriation of money for the use of the board, although the original form of the bill proposed the sum of $3000.

Proposed Iowa Bill

The Iowa bill is also largely a copy of the Joint Committee bill, but provides for separate certificates to land surveyors. The board of examiners is composed of five, instead of nine, members, no two of whom shall be from the same branch of the profession; their compensation is at the rate of $10 per day. Each year in a recognized engineering school, if successfully completed, is allowed as equivalent to engineering practice in the six-year requirement. The fee for examination is $15, and for certificate $10 additional. For six months after the passage of the bill, certificates may be issued for $25 fee, to professional engineers or land surveyors of two years' practice immediately preceding the date of passage. Violation is a misdemeanor punishable by fine of $100 to $500, or by imprisonment for three months, or both.

Application of this act does not include full-time employees of corporations unless the latter offer their services to the public as professional engineers or land surveyors; if so, all principal designing or constructing engineers must register. Assistants to registered engineers or land surveyors are also exempt.

Idaho Legislature Passes Licensing Bill

The Idaho legislature, which recently adjourned, passed a bill providing for the licensing of civil engineers. Civil engineering is defined as "the practice of any branch of the profession of engineering other than mining, metallurgical and military."

The department of law enforcement of the state Government is empowered to conduct examinations, to pass upon the fitness of applicants for reciprocal registration from other states, to prescribe rules for holding examinations, to determine what shall constitute a school, college or department of a university for civil engineers and the reputability and good standing of such schools (the requirements of the University of Idaho for the degree of civil engineering are adopted as the standard), and to conduct hearing on proceedings to revoke certificates.

Seven persons, each a registered civil engineer of

recognized standing and having had ten years' active practice, and a resident of the state for at least one year, are to be appointed to hold the examinations. Appointments are to be made after giving due consideration to recommendations by members of the civil engineering profession and organizations. The members of this board are to receive per diem allowance of $5 and mileage.

The fee for residents of the state is to be $10 and for applicants from outside $25. Applicants shall be of good character, more than 21 years of age, have been in active civil engineering work as assistant or otherwise for at least six years, or shall be graduates of a recognized school. To any person having these qualifications and having been actively engaged in the practice of the profession for one year will be granted a certificate on payment of the fee and taking of an oath, without having to pass an examination. A person registered in any other state having a minimum requirement not less than that of Idaho may be registered without examination, in the discretion of the department. Certificates may be revoked for any of the following grounds: 1, Fraud or deception in procuring certificate of registration; 2, fraud or deception in practice, or 3, conviction of a felony.

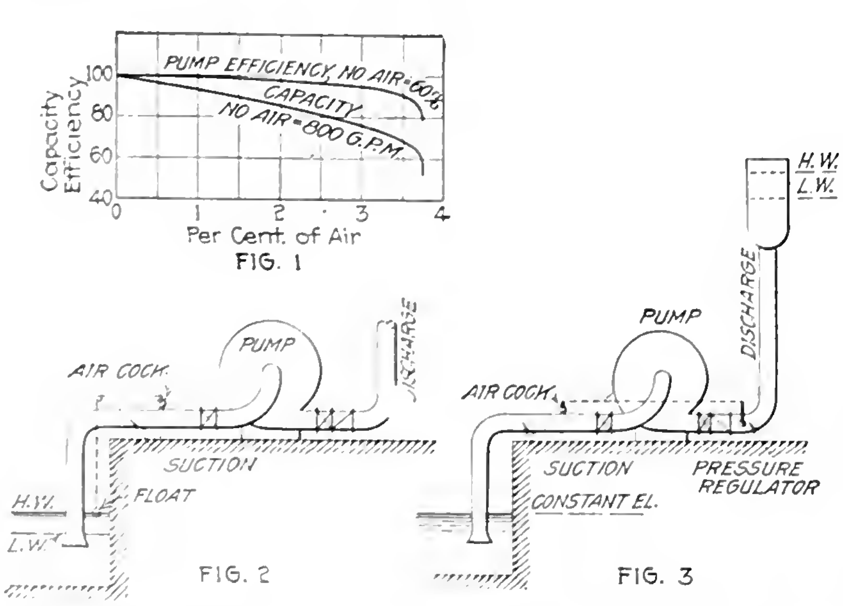
The act does not apply to engineers in the employ of the United States Government; nor to engineers employed as assistants to registered engineers, nor to non-resident engineers coming into the state for consultation, to collect information or to give expert testimony in court.

Tests Determine Effect of Air in Centrifugal Pump

By A. P. Blackstead
Camden Iron Works, Camden, N. J.

Some time ago the writer conducted a series of tests in order to determine the effect of air let in on the suction side of a centrifugal pump.

The pump had 5-in. suction and discharge nozzles and was direct-connected to a constant-speed electric motor. The power input was measured with standard, calibrated instruments. The water pumped was weighed on standard scales, the suction and discharge heads being measured by mercury columns. A small gas meter, with inlet open to the atmosphere and outlet connected to the suction pipe, was used to determine the amount of air let in. The valve in this line controlled the amount of air. By throttling the gate valve in the main suction line a constant vacuum of 20-in. mercury was obtained simply by regulating the discharge gates where a constant total head of 60 ft. was obtained.



ARRANGEMENT TO MEASURE EFFECT OF AIR ON PUMP

The test was repeated several times, each time giving substantially the same results, which are graphically shown on Fig. 1. It will be noted that whereas the capacity took a decided drop with the increased percentage of air, the pump efficiency remained virtually constant up to a point where the pump would not handle any more air, 3.75% volumetric, where it dropped the suction. A very small amount of air, 3.12%, reduced the capacity 25 per cent.

This offers an easy method of regulating the capacity of a centrifugal pump which is working under suction. Fig. 2 shows a schematic arrangement for such a control where it is desirable to regulate the pumpage by the fluctuation of the water in a suction well, as is often the case in sewage installations. If, on the other hand, as in water-works service often is the case, the pump capacity is to be regulated by the elevation of the water in the standpipe, a similar arrangement can be made with the air cock controlled by the variation in the water pressure. This is indicated in the illustration, Fig. 3. This control will eliminate a number of objectionable features in connection with the usual automatic regulation of starting and stopping or change of speed.

It will be noted that the cost of this outfit would be very small. The control would work equally well on large and small pumps and could be applied to existing pumps without difficulty.

Winter Concreting on Miami Conservancy Work

Concreting has been carried on through the winter in the dam-construction work of the Miami Conservancy District, Ohio, with only occasional interruptions. As the nature of the enterprise demands that progress be rapid and according to schedule, and as it is important to keep the working organization intact, to avoid losses and delays, it became necessary to plan reducing the interruptions of concreting to a minimum.

Study of the extra costs involved in heating materials and protecting deposited concrete led to the conclusion that the greater part of the extra cost is incurred only at temperatures below 20 deg., and a general rule was therefore made that work through the cold season is to be continued until the thermometer drops below 20 degrees.

Provision for heating aggregates by steam coils built in the bins has been made at all three of the dams where concreting has been going on, Englewood, Germantown and Lockington. Means have also been provided for protecting the surfaces from freezing by tarpaulins and salamanders, or, in some instances, by steam coils (where steam was available because it was used for other purposes).

Care is taken that no fresh concrete is placed on frozen foundations. With a view to reducing the liability of freezing also, the amount of water used in mixing is closely regulated.

At two of the dams most of the concreting has been in footing trenches, and, as this situation protects the concrete from wind, protection from freezing is relatively simple. At Lockington, however, the concrete walls under construction project high above ground and are more difficult to protect; work at Lockington has therefore been held up in cold weather during a greater part of the time than at the other dams

Effect of Cold-Working and Rest on Endurance of Steel

Cold Pressing and Rolling Have Slight Effect on Results of Reverse Stress Tests—No Gain from Rest Periods

ALTERNATE-STRESS tests were applied to the investigation of a new question by Prof. H. F. Moore and W. J. Putnam of the University of Illinois, during the past year. Their results were reported to the American Institute of Mining Engineers last month in a paper entitled "Effect of Cold-Working and Rest on the Resistance of Steel to Fatigue under Reversed Stress." Briefly, they sought to determine whether the improvement in strength and elastic limit of a piece of steel by cold-working, such as rolling, stretching or compressing, is accompanied by improvement in the endurance of the steel under reversal of stress many times repeated. Furthermore, since it is known that the effects of overstrain are diminished by a period of rest (as well as by low heating, such as through immersion in boiling water), it was desired to find whether rest benefits the fatigue strength. Essentially, the results of the many series of tests made to answer these two questions were negative. That is, cold-working does not increase the fatigue strength, although it also does not distinctly decrease it; and no marked benefit through rest could be detected.

Underlying the experiments was the thought that the service of steel is in the last analysis determined by its resistance to repeated stress—in other words, its endurance—and only in less degree by its static qualities, such as tensile strength and elastic limits. If, therefore, the marked raising of elastic limit in steel through cold-working is paralleled by a raising of the fatigue strength, very important practical conclusions would follow.

For some years Professor Moore has studied fatigue tests on the hypothesis of the exponential law as a satisfactory working formula. According to this law, the number of repetitions of stress which a given material will stand is in inverse proportion to some power of the unit stress applied. The hypothesis is convenient because the curve connecting unit stress and number of repetitions becomes a straight line when plotted on logarithmic paper, which greatly facilitates the comparison of experiments made in widely different ranges, though it does not remove the possibility of committing serious error in such extensions from one range to another. Experiments have given a fair degree of support to the exponential hypothesis. It is on the safe side because it calls for a low working stress for very great numbers of repetition.

In the series of tests summarized in the three diagrams of Fig. 1 the Upton-Lewis vibratory testing machine was used. This works on a flat specimen, in this case a strip having a reduced section about ⅝ in. wide and about 2½ in. long, and gives complete reversals of bending stress at the rate of 250 per minute. Other tests, one series of which is summarized in Fig. 2, were made on the White-Souther machine, which uses a cylindrical specimen, in this case ½ in. in diameter and 4½ in. long from edge of support to center of bearing of load.

In Fig. 1 the points representing the individual tests are not marked, but Professor Moore has stated that they are not much more scattering or distant from the lines drawn than the tests shown in Fig. 2. However, many of the tests were to the left of the section of curve drawn; that is, they were above the static elastic limit (as determined under the American Society for Testing Materials' specification, by the sudden increase of rate of stretch of a tension specimen as shown by the extensometer).

Briefly, the comparative endurance of two specimens represented by two different lines on the diagram is to be estimated by the position of the lines above or below each other; the upper line indicates material of greater

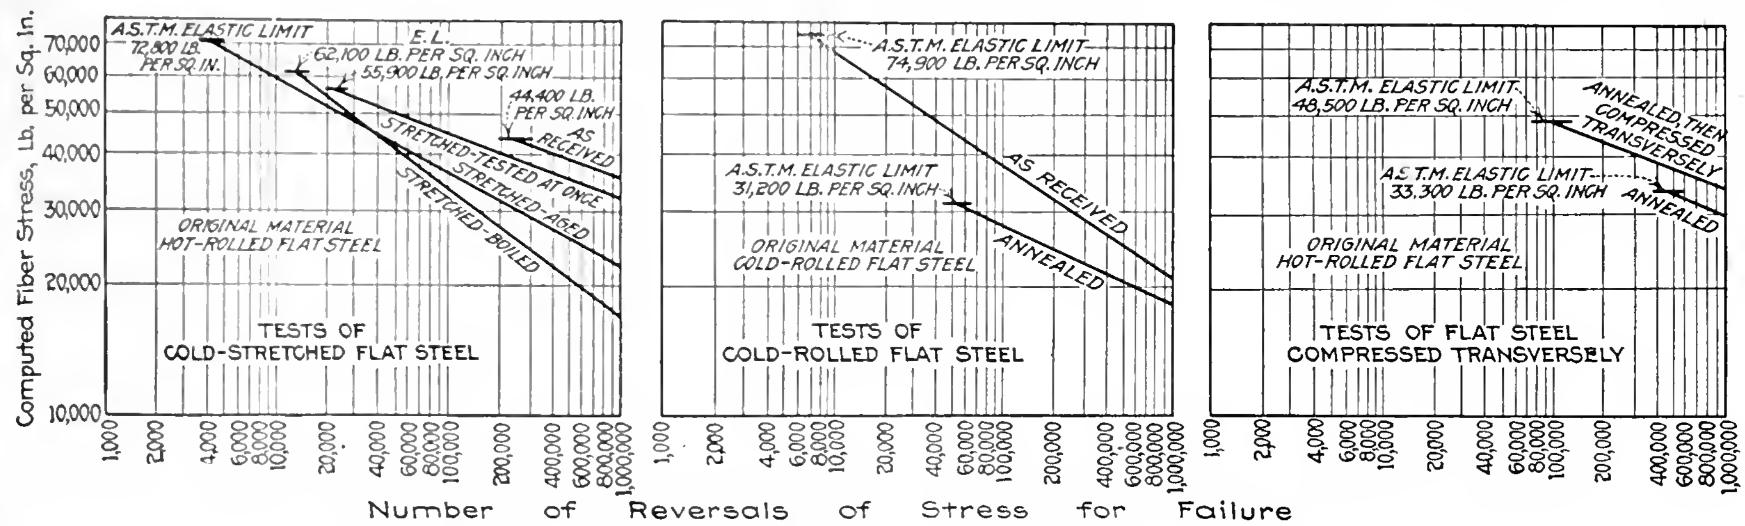


FIG. 1. FATIGUE TESTS WITH UPTON-LEWIS MACHINE TO DETERMINE EFFECTS OF COLD-WORKING ON THE ENDURANCE OF STEEL

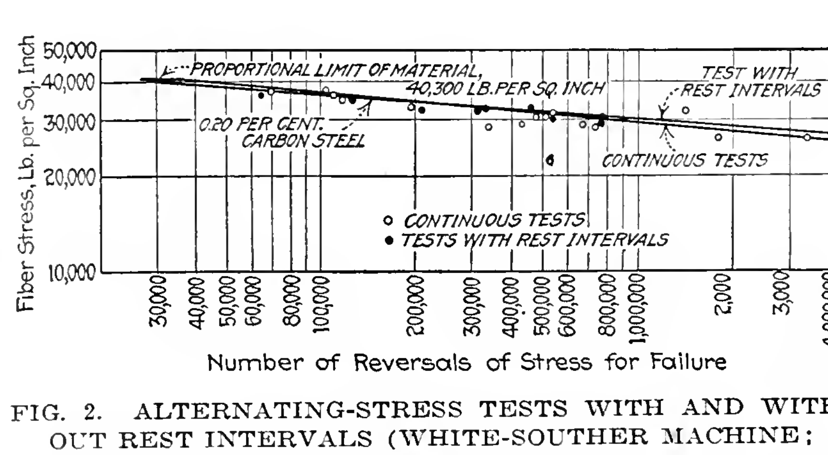

FIG. 2. ALTERNATING-STRESS TESTS WITH AND WITHOUT REST INTERVALS (WHITE-SOUTHER MACHINE; STEEL 0.20% CARBON)

endurance. Judged by this criterion, it will be seen that in the first diagram of Fig. 1 the (hot-rolled) material was of better endurance in its original condition than after cold-working by stretching, or after 60-day aging or 15-minute boiling treatment subsequent to the stretching. In the second diagram of the same figure cold-rolled material showed better endurance in its original condition than after annealing, which effect is the opposite of that indicated by the preceding diagram. The explanation may be that cold-rolling involves a compressive action and for that reason strengthens the material in endurance, while the cold-stretching in the previous diagram weakened the material. The same indication may be gathered from the third diagram of Fig. 1, in which hot-rolled material strained by transverse squeezing showed slightly better endurance than the same material not compressed. In any event, however, the effect of the cold-working on endurance is not great, and the practical conclusion is that cold-working does not have any marked effect on the endurance of the metal, although it modifies very profoundly the elastic limit and other static tensile properties.

Various series of tests to investigate the effect of rest after cold-working are fairly typified by the diagram reproduced as Fig. 2. It is to be concluded from this that the rest intervals (either one or two, of 24 hours each) did not improve or otherwise change the endurance qualities of the material.

In view of the fact that failure in endurance tests has been shown to be due to the slow opening up of separations between the grains of the metal, starting probably from some slight local defect, it is not an unexpected result that rest has no effect in restoring the damage done by the previous repetitions of stress. The starting and gradual growth of this detailed failure in alternating-stress tests has been shown most strikingly by Professor Moore through moving-picture microphotographs that were taken of a small polished and etched spot on the side surface of one of the endurance specimens.

Sanitary Service Rids Construction Camp of Influenza

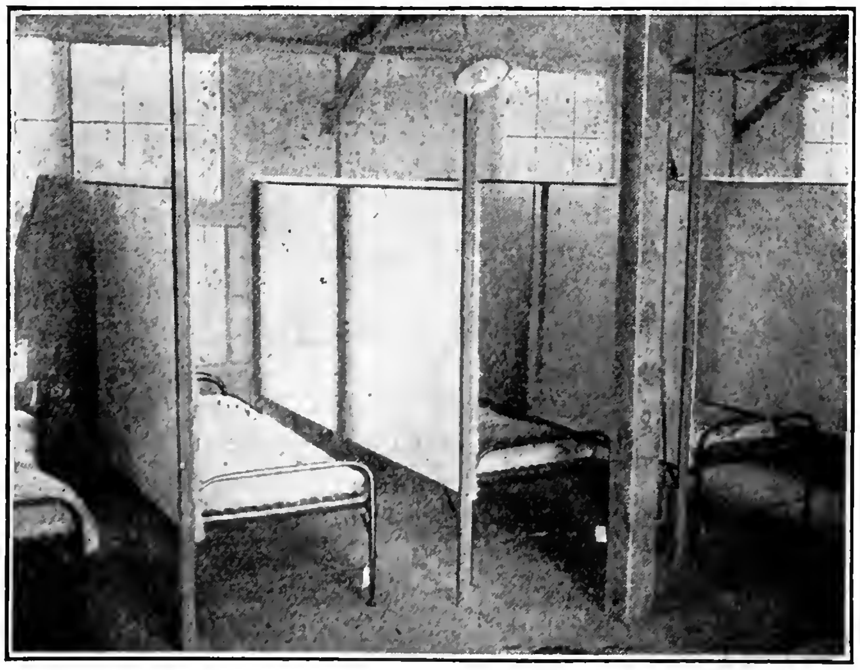
Strict Enforcement of Ordinary Sanitary Precautions Kept Intact Working Force on Camp Custer Extension When Surrounding Communities Were Decimated by Disease

By M. D. Kauffman
Division Engineer in charge of Sanitation, Camp Custer Extension

During the height of the influenza epidemic last autumn the construction force building the extension to Camp Custer suffered no diminution on account of disease. Instead, the superior reputation for healthfulness of the camp led to an increase of 50% in the applications for work. Construction progress was maintained at scheduled speed while on neighboring jobs work lagged because of workmen lost through disease and desertion, and communities all about had closed theaters, schools and churches and were conducting all business under quarantine restrictions. Specifically, from Oct. 6, when the working force was 1281, to Nov. 15, when it was 2572 men, there were four cases of influenza and one case of pneumonia, and altogether only 14 cases of sickness demanding the attention of a physician. By this time 65% of the work was completed. From Nov. 15 to Dec. 31, when the working force fell from 2572 to 1080 men and 95% of the work had been finished, only 10 more cases of sickness occurred. Thorough sanitary service explains these facts.

Success in sanitary service at Camp Custer came from attention to detail. No unusual hygienic or sanitary measure was employed; also, no essential hygienic precaution was neglected, and no carelessness in its execution was permitted which vigilant inspection could prevent. The story to be narrated is, therefore, a story of details and not one of general practices.

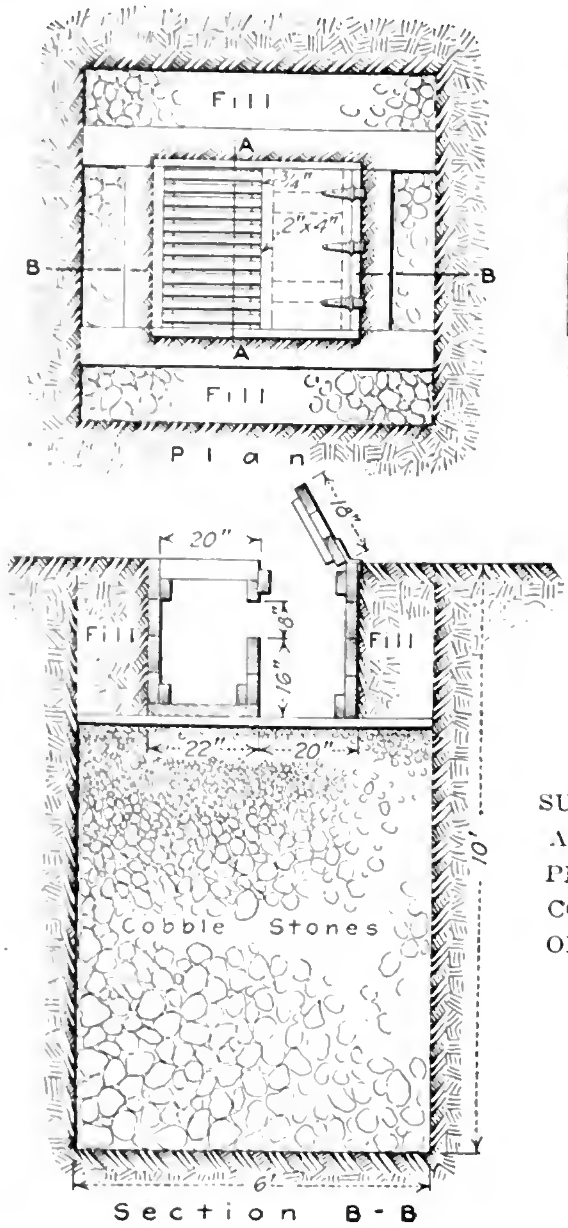
Camp hygiene began with personal cleanliness, and no other single provision counted so high toward the sum of the results obtained. Ample and comfortable facilities for body bathing and for washing clothing were provided. Every workman was required to bathe thoroughly once a week. Men having the handling of food in any way had to bathe twice a week, to brush their teeth daily and to wash their hands frequently. Discharge followed refusal to comply with rules for bathing or refusal to change frequently to clean clothing. Lavatory attendants and bunk-house caretakers kept careful watch to detect lack of cleanliness. If carelessness was observed the man was reported and subjected to such examination as seemed required. If communicable disease was discovered, the workman was isolated and his personal effects were disinfected, or



WALLBOARD SCREENS BETWEEN COTS CONFINED SPRAY FROM SNEEZING

he was handed over to a physician or to the hospital, as the circumstances required. If body vermin were discovered the man was isolated until the trouble was eradicated. Refusal by the workman to submit to these requirements was met by discharge from the camp. All but a very few of the men coöperated cheerfully in maintaining the high standards of personal hygiene.

Bunkhouses accommodated 65 men, and at the height



SURFACE WATER ACCUMULATION PREVENTED BY CONSTRUCTION OF DRAINAGE PITS

of progress 20 of them were occupied by an average of 1200 men. All were furnished with iron cots and straw ticks; cots were set 20 in. apart and were cubicled off by semipartitions of wallboard arranged as illustrated. These partitions reduced the danger of infection from spray from coughing and sneezing and did not interfere with ventilation.

Each bunkhouse had a day caretaker and a night caretaker. After the workmen left the bunkhouse in the morning the day caretaker opened every window full top and bottom and kept it open four hours. All blankets were removed from the beds and hung outside for a period of six hours daily when the weather permitted. Every Monday, cots and ticks were put outside and sunned and aired for four hours. Cots, floors and wall surfaces were sprayed daily with 5% lysol solution. Floors were swept morning and afternoon and scrubbed at least twice a week. Before each sweeping the floor was sprinkled with sawdust saturated with a solution of 5% lysol, 5% formaldehyde and 90% water. A half hour after sweeping all flat surfaces were wiped with a damp cloth or oil duster. All woodwork, including the floors, partition supports, etc., was scrubbed once a week with soap and water, and windows were cleaned and polished once a week.

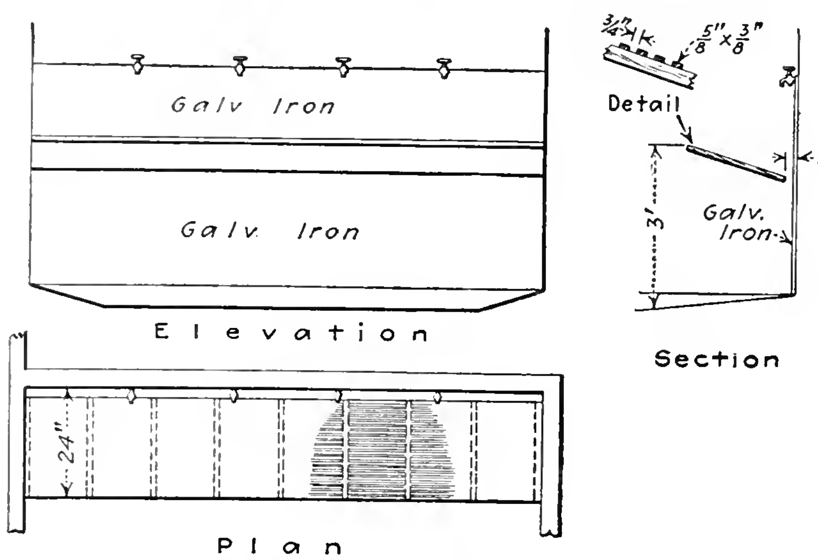
BLANKETS SUNNED AND AIRED FOUR HOURS EVERY DAY

Spitting, except into cuspidors, was prohibited within or adjoining bunkhouses. Six cuspidors were provided for each floor. All were emptied daily and the contents were removed to the dump and buried. The cuspidors were then scrubbed inside and outside with soap and water and refilled with clean sand sprinkled over the top with chlorinated lime.

The spread of vermin was prevented by examination of the clothing of men applying for accommodations; by daily inspection of walls, cots and bedding; by spraying walls, cots and ticks monthly with a solution of two drams of chloride mercuric and 16 oz. of wood alcohol; by prohibiting the keeping of food or of cast-off clothing in the bunkhouses.

Rules for ventilation at night required that eight windows, three in each side and one in each end, be kept full open from 9:30 p.m. to 4:45 a.m. Inspection was made nightly to enforce this regulation.

One attendant was assigned to each compartment containing 24 water closets, 30 ft. of urinal trough, 10 showers and 30 ft. of wash trough. The floors were scrubbed every morning, and swept and mopped every afternoon and evening. Walls, doors and woodwork were scrubbed weekly with soap and water. Cuspidors in the lavatories were emptied and scrubbed twice daily. Water closet bowls were washed with soap and water and scoured inside each day with lye. Incrustations in the bowls were removed with muriatic acid. Water-closet seats and the wood in wash troughs were washed three times a day. Urinal troughs were



FREQUENT LAUNDRY TUBS ELIMINATED EXCUSES FOR DIRTY CLOTHING

scrubbed and treated with kerosene or crude oil every morning and afternoon.

Privies were used only when work had to be done before sewerage was installed. One attendant took care of three privies. Floors and troughs were scrubbed twice a day, and seats were washed with soap and hot water three times a day. Chlorinated lime was used freely in vaults and troughs and the ground under the troughs was kept soaked with crude oil. When a privy was abolished, 6 in. of air-slaked lime was spread over the contents of the vault, and it was then filled to within 6 in. of the surface. The ground for 3 ft. around the vault was then excavated to a depth of 6 in. The excavated and vault area combined were then covered with burlap soaked in crude oil. The area was then filled to the surface with cinders.

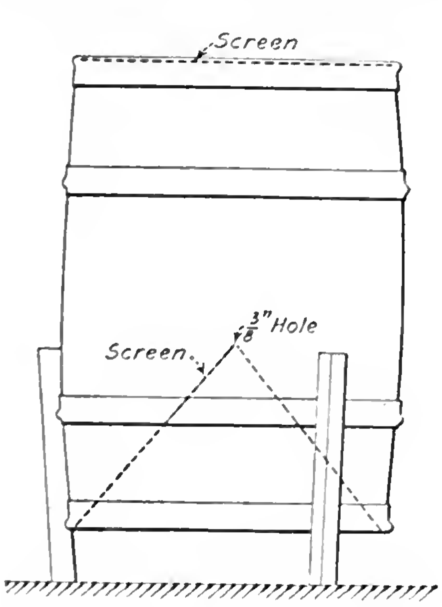
One or two collections of waste were made daily. A morning collection covered the whole camp area and included all waste; an afternoon collection covered the occupied area only and included only garbage and refuse.

Two two-horse teams, each with a driver and two men, did the collecting. Garbage was handled in 40-gal. covered cans, and 15 cans were a wagon load. For ashes and refuse the wagon bodies were divided by movable partitions into a forward compartment for refuse and a rear compartment for ashes. Ashes were used for filling depressions and for drives; refuse and garbage were taken to the dump. At the dump the garbage was burned and the cans were washed for return to the mess halls. Refuse was first sorted for materials having a salvage value, then the remaining combustible materials was burned and the incombustible material was piled. Three men at the dump assisted by the men on the wagons sorted and salvaged the refuse, buried the garbage and burned or piled the waste. A record of salvage kept for eight days, for roofing paper, lumber, cement sacks, nail kegs and tools, showed enough value recovered to meet the cost of 15 men and four teams required for street cleaning, refuse removal, dump service and the filling of the water barrels.

Manure from the stables accommodating 200 horses was handled separately. There was an attendant for each 20 stalls. Each morning and noon the stalls were cleaned and sprinkled with crude oil or quicklime. Manure was collected in piles outside the stables and removed daily to adjacent farms and spread on the land. After removal, the ground where the piles had been was sprinkled with quicklime. If delayed removal permitted fly larvæ to develop, the piles were sprinkled with a solution of 1 lb. of powdered hellebore and 25 gal. of water.

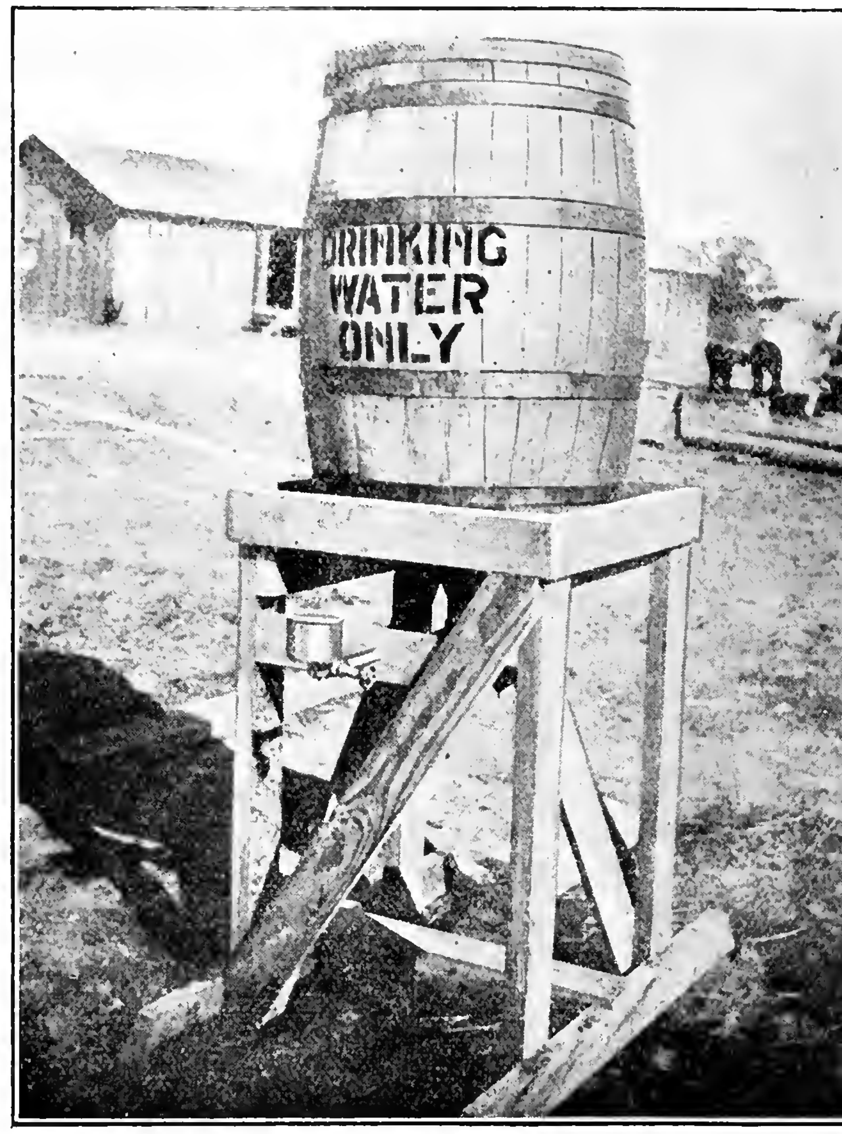
Rubbish, garbage, manure and all other forms of decomposed matter that could attract flies were protected until disposed of. Garbage platforms were scrubbed and disinfected daily. All rooms were screened and provided with fly paper. Fly traps baited with vinegar and sugar, stale meat and banana skins were placed in all locations where flies were observed to congregate.

To eliminate mosquitoes all small pools were filled, and every place in which water could accumulate was eliminated. Filled fire barrels were filmed with oil.



BARREL TRAPS REDUCE FLY PEST

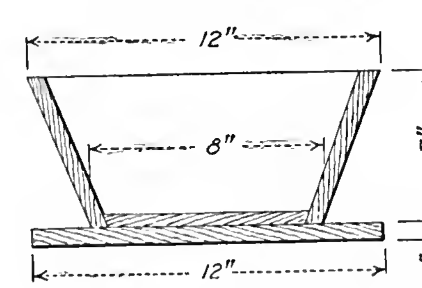
Water supplied from Camp Custer was of established purity, and the only precaution necessary was to keep it uncontaminated. For drinking purposes, improvised bubbling fountains were located at convenient places about the work. On isolated jobs, where the installation of fountains was not warranted, paper drinking cups were issued to the men and water was carried to them in covered pails. Common drinking cups



BUBBLE FOUNTAIN IMPROVISED FROM WATER BARREL AND TIN CUP

were absolutely prohibited. As an inducement to the workmen to keep their quarters clean and orderly, as well as to provide an essential item in complete sanitary service, the streets and grounds were kept clean. A force of one foreman and four laborers was provided. The streets and roadways were cleaned daily, and the grounds were raked every morning and policed all day to remove stray accumulations. Besides doing routine cleaning, the force filled in damp hollows, dug small drains, banked around buildings, repaired walks, and did other necessary work.

Not including mess-hall sanitation, which will be described in an article to be published later, the sanitary squad during the week of Nov. 8-14, when operations were most active, comprised 80 men, of whom 23 were on night duty. During this week the average daily working force was 2421 men, and an average of 1175 men was housed daily in the bunkhouses.



CUSPIDORS PLENTIFULLY PROVIDED

The construction of the extension to Camp Custer was under the direction of Maj. T. A. Leisen, constructing quartermaster. Samuel A. Greeley of Chicago was supervising engineer. The W. E. Wood Co., of Detroit, Mich., was general contractor. The writer, M. D. Kauffman, of Chicago, was division engineer in charge of sanitation. Valuable supervision and inspection work was also done by Lieut. G. W. Long, United States Army.

Ditch and Road Work Combined on Drainage Project

Spoil from Drag-Line and Wheel Excavators Builds Roads—Engineer Uses Tractor Plows to Break Heavy Surface Mat

TO OPEN up for settlement an area of 40,000 acres of swamp land the Virginia-Carolina Farms Co., Beaufort, N. C., is constructing a system of drainage ditches, and is utilizing the excavated material for roads along the section lines. The land lies north of Beaufort, between the Neuse River and Gore Sound, and is 12 to 16 ft. above sea-level, with a slight slope toward both waterfronts. It has about 4 ft. of wet muck over a clay stratum. The nearest railway is 12 miles distant, and a wharf will be built on the Neuse River waterfront to accommodate river craft.

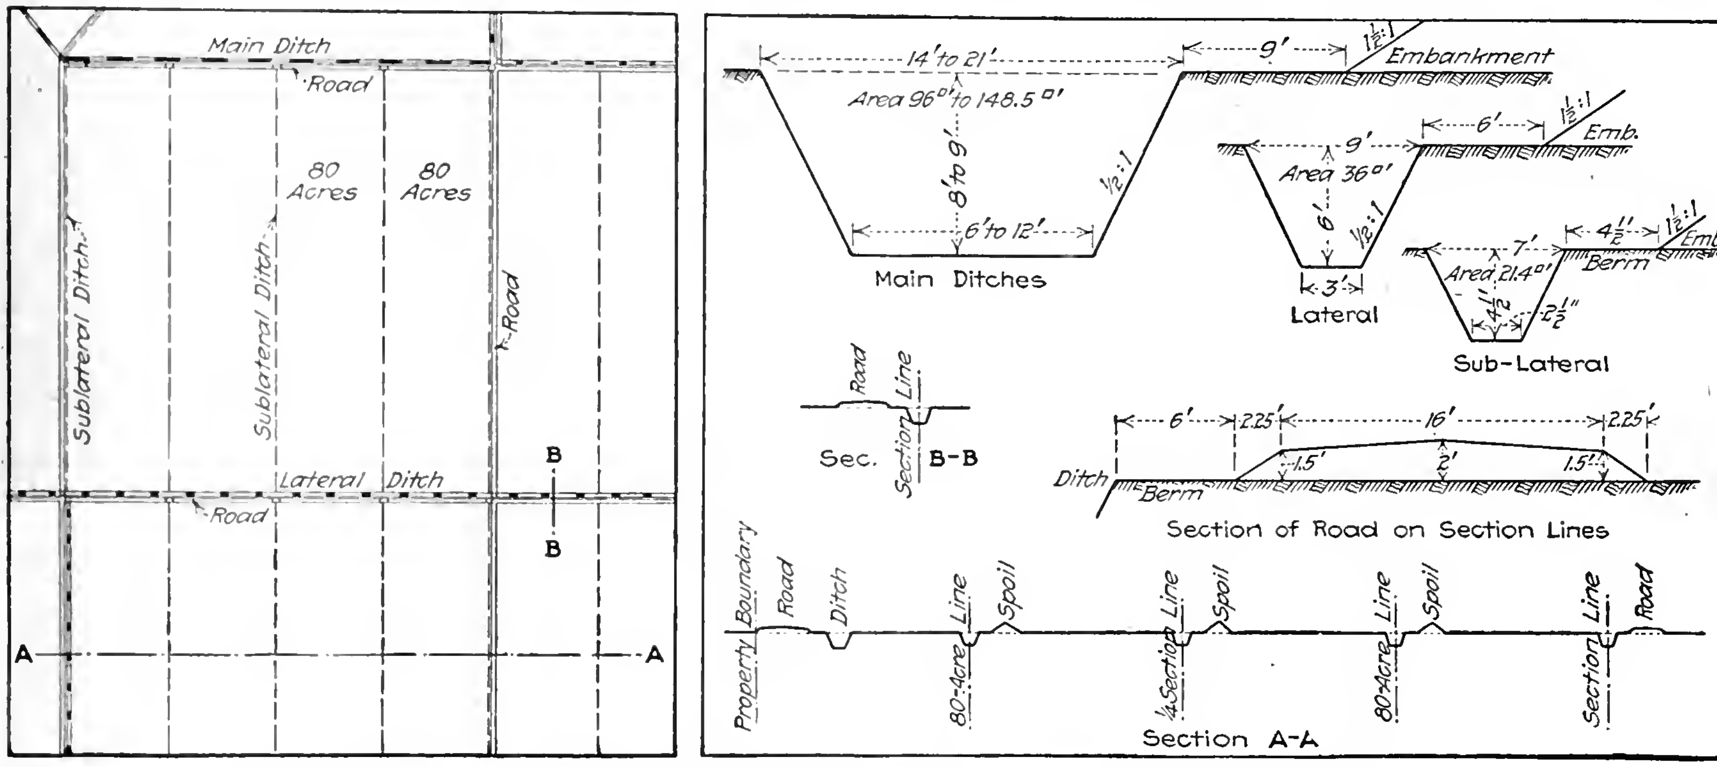
Land in that part of the country is not laid out on the ordinary rectangular section system, but is in irregular tracts described by metes and bounds. As most of the trees and other marks used as the original survey points disappeared long ago, and as the creeks whose center lines were recorded as boundaries have shifted their positions, it was no easy matter to determine the boundaries of the area to be improved. It is of irregular shape, but the topographic conditions were favorable to a rectangular subdivision, with main and lateral ditches following the section and lot lines, and roads paralleling the section-line ditches.

Shrinkage of the soil due to drainage is expected to cause an average settlement of 10% in the depth of the muck stratum, but as all the ditches are bottomed in the stiff clay substratum this settlement will not affect the drainage works. The main ditches slope in two directions, to the two waterways mentioned.

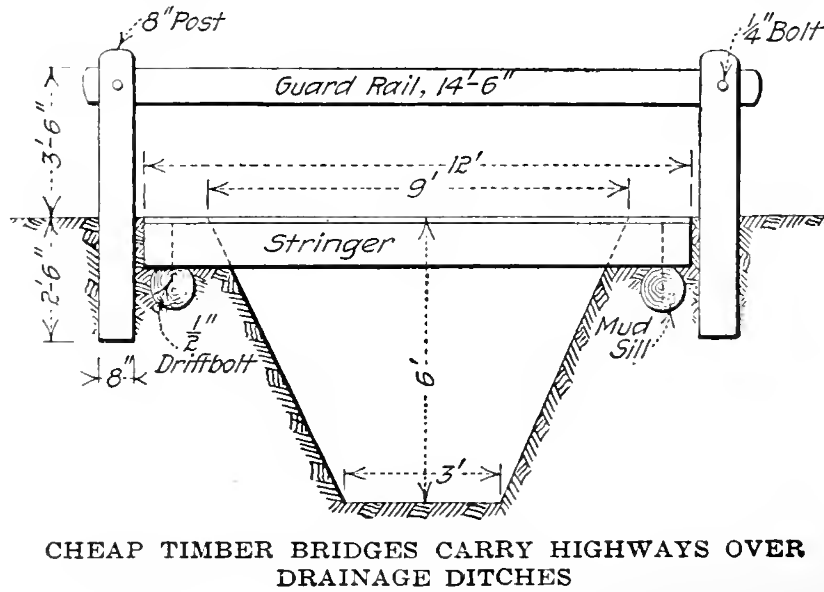
There is little timber on the drained area, but some timber land is adjacent. The surface growth is largely gallberry-fetter bushes and also bay bushes and vines, whose roots cause a dense mat about 9 in. thick. Handling this mat is a difficult problem, as it will not burn, even when the growth is cut and burned. Experiments made by the engineer indicated successful treatment by deep plowing and rolling. A 6-ton caterpillar tractor developing 3000 lb. drawbar pull hauled a plow with two 18-in. bottoms which cut through the mat and threw it in furrows. The plow would not turn the furrows so as to bury the mat, but the plowed surface was spread and leveled by running over it with the tractor in such a way as to press the former top of the mat down into the muck. The soil is so sour that it must be treated with lime and left for about a year before it can be used for crops.

Main ditches have a bottom width of 6 to 12 ft., with slopes of ½ on 1 and a depth of 8 to 9 ft. Laterals have a minimum bottom width of 3 ft., with 6 ft. depth; and sublaterals a 2½-ft. width with 4½-ft. depth. In all cases, the berm width is equal to the depth of the ditch. For the roads, the spoil bank is leveled down and topped with the clay, forming a fill of the section shown. Numerous bridges are required. These are of very simple construction, consisting of stringers drift-bolted to mudsills placed about 18 in. back from the edge of ditch and carrying two layers of 2 x 12-in. planks, 14 ft. long. Posts set in the banks carry guard rails, as shown.

Excavation was done by a dragline machine of the walking type and a wheel-type machine mounted on



DITCH AND ROAD LAYOUT PROVIDES FOR RECLAMATION OF WET LAND



CHEAP TIMBER BRIDGES CARRY HIGHWAYS OVER DRAINAGE DITCHES

caterpillars. The former had a 1-yd. bucket. The latter, with buckets on the rim of the wheel and inclined side-arms to cut the slopes, could excavate a finished ditch at the rate of 8 ft. per minute.

There was considerable trouble in obtaining and keeping a labor supply, the men available being independent and their work poor in proportion to the wages paid. The labor force averaged 80 men. Work was commenced in January, 1917. W. H. Rosecrans, Chicago, is engineer for the company, with W. H. Winsett as resident engineer. The contractors are William H. Esson and Roberts Brothers, Chicago.

Indianapolis Garbage-Reduction Profits

NET profits of nearly $15,000 are reported from the operation of the garbage-reduction works of Indianapolis from May 26 to Dec. 31, 1918. On the former date the works were taken over for $175,000 by the Board of Sanitary Commissioners of the Indianapolis Sanitary District, which has since operated the plant. During the approximately seven months of public operation 12,187 tons of garbage and related material were treated, at a total cost of $72,550 or $5.95 per ton, including capital charges. In more detail the figures were:

		Per Ton
Operating revenue:		
Grease	$63,666	$5.22
Tankage	19,502	1.60
Hides	4,259	....
Total	$87,427	
Operating expenses:		
Plant department	$36,371	$1.21
Transportation	7,090	.58
Purchase of dead animals	5,511	....
Purchase of meat and grease	1,355	....
Total	$50,327	
Capital charges:		
Depreciation	$17,500	$1 43
Interest on bonds	4,703	.38
Total	$22,203	$1.81
Total annual revenue	$87,427	....
Total operating and capital charges	72,530	....
Net income	$14,897	$1 22

Attention is called to the income of $37,100, which is the difference between the total income and the operating expense. Out of this amount the sum of $17,500 has been laid aside for depreciation. This is for a seven-month period and is at the rate of $30,000 per year. At this rate, Jay A. Craven, member and secretary of the commission says, the plant will more than pay for itself in a five-year period, as at the end of that time the plant will be in in an operating condition and worth considerable money even as scrap value. In addition to depreciation, the interest on bonds, $4703, has also been allowed for the seven-month period. After deducting these two items, Mr. Craven states, a net profit of $14,897 remains, which represents a return of 8½% on the investment of $175,000.

In addition to a favorable return on the garbage plant, says Mr. Craven, a considerable saving not shown in the figures above, is being made in the collection end. In the seven-month period during which the city did the collecting in 1918, the total cost was $29,766. This covers the summer months, when the costs are heaviest. On this basis, however, the costs for the year would be $51,000, approximately $2000 more than the old contract price with the former reduction company, and $36,900 less than the new price of $87,900, the amount of a bid received for the collection and reduction of garbage for a year.

Mr. Craven sums up by saying that by taking over garbage collection and disposal the city has saved at the rate of $37,000 a year to the taxpayers, neglecting altogether the net profit of practically $15,000 for a seven-month operation of the garbage-reduction plant.

Auxiliary Outlet Gate Relieves Main Gates of Dam

Drillers on Suspended Platform Cut Opening in Gate Well to Avoid Operating Main Gates Under High Head

By R. C. E. Weber,

Assistant Engineer, United States Reclamation Service, Orland, Calif.

OPERATION of the original service gates at the East Park Dam of the Orland, Calif., project of the United States Reclamation Service has always been somewhat difficult under high heads. The gates are 48 x 60 in. When operated under the full head of 65 ft. for the first time in 1911, scoring of the bronze bearings resulted. New bearings were substituted in 1911 and 1912 on both gates, which resulted in improvement in that the new bearings did not score, but still under full head the gates were operated with considerable difficulty.

To eliminate the necessity of operating them under high head it was determined to install an auxiliary gate at a higher level which would furnish sufficient discharge till the water surface in the reservoir reached an elevation that would permit of operating the lower

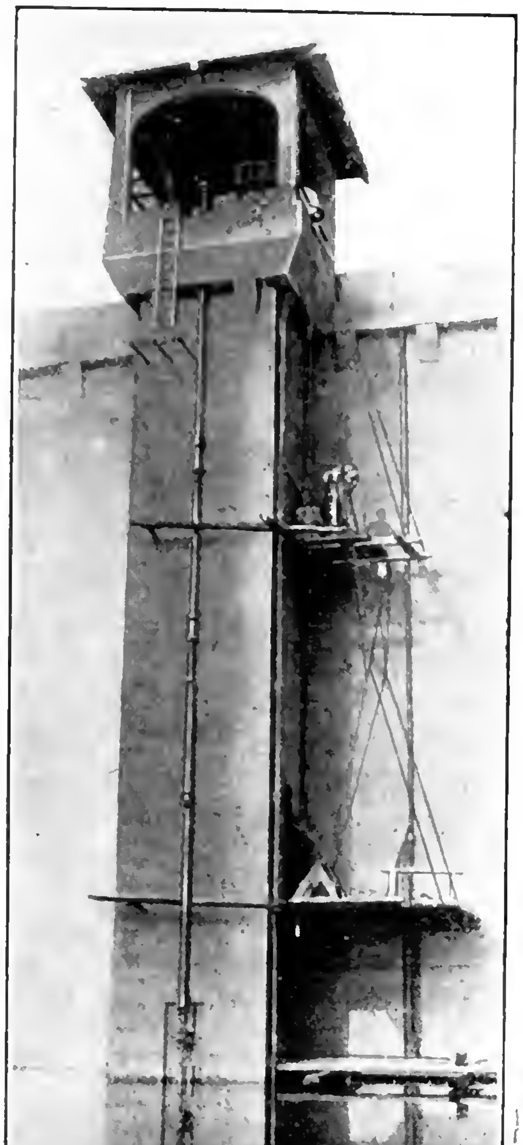
PUTTING ADDITIONAL GATE IN GATE WELL AT DAM

gates with less difficulty. Accordingly a 36 x 36-in. gate was designed, to be located in the north side of the gate well, with its sill at El. 152. Full reservoir level is at El. 188. The gate was designed by the Denver office of the United States Reclamation Service.

The work of installing the gate was commenced on Oct. 12 and completed Nov. 5, 1916, with a force con-

sisting of the writer in charge and two experienced drillers. With the exception of the help of an additional man at the time of raising the gate stem into position, this force performed all the work of installation. The water in the reservoir stood at El. 143, or 43 ft. above stream-bed level at the dam, which precluded the use of scaffolding.

A platform 8 x 12 ft. was suspended from the top of the gate well by means of wire ropes and was secured with its floor 18 in. below the sill of the new gate. The 36 x 36-in. hole through the tower wall, 21 to 24 in. thick, was driven by first drilling a 1½-in. hole and then removing the concrete with steel gads and sledgehammers. The opening was completed in 1½ days by the two drillers. No reinforcing was encountered, the walls of the gate well being plain concrete. The 12 horizontal holes for the bolts securing the gate frame were drilled with ⅞-in. drill steel fitted with a 1½-in. bit. In drilling the vertical hole through the 4-ft. tower coping, for the 2 11/16-in. gate stem, a 1-in. core hole was first drilled and followed by a 4-in. drill. The smaller hole was made to avoid cleaning while working the 4-in. drill and also to serve as a guide for the latter. Numerous large stones were encountered by the larger drill and the resulting hole was irregular in section. It was rounded out by means of smaller drills and chisel-pointed steel. The rocks encountered were boulders, and very hard to drill and break.



LOWER PLATFORM IS FOR WORK AT GATE AND GATE OPENING. UPPER PLATFORM IS FOR PLACING THE GUIDES OF GATE STEM

For drilling the four horizontal holes for each of the three stem guides, a smaller platform with floor 4 x 6 ft. was swung from the top of the gate well. This platform was of such weight that it could be raised and lowered readily to the different elevations of the stem guides. The holes for the stem guide bolts were drilled after the gate frame, leaf, stem and stand had been properly adjusted.

The gate stand was taken to its position on the top of the gate well by means of the steps leading to the top of the dam. Block and tackle were used in raising and lowering it over the steps. The gate frame, stem and leaf were floated to the dam on a raft and hoisted into position by means of a 4-part line of 1¼-in. manila rope and double blocks. A lead gasket 1½ in. thick was placed between the concrete and the gate frame. This was calked after the frame was secured to the wall by anchor bolts, thus securing an even bearing for the frame as well as a watertight junction between wall and frame. All anchor bolts for the gate frame and the stem guides were grouted into place with a rich mixture of sand and cement. Holes for the anchor bolts for the gate stand were drilled after final adjustment of the stem and stand. These bolts were secured to the floor of the gate well by babbitt. The total weight of the gate complete was 3017 pounds.

Engineer Arbitrators Fix Value of Water-Company Property

Time and Money Saved by Engineers on Ground After Their Representatives Had Made An Inventory

BY FARLEY GANNETT
Consulting Engineer, Harrisburg, Penn.

ONCE more a board of engineers has satisfactorily and promptly valued a water-works plant for purchase by a municipality. On July 1, 1918, the Borough of Huntingdon, Penn., purchased the plant of the Huntingdon Water-Supply Co., after years of controversy in the courts. The purchase followed the award of a board of arbitrators consisting of five engineers. The price set by the board was $157,684.

When the plant was built in 1885 a clause was inserted in the franchise providing for the right of purchase by the borough at the end of each ten-year period, the value to be set by a board of five engineers from which there was to be no appeal. The borough had the right by the contract with the company to refuse to buy the plant after the price was set by the arbitrators, but the sale took place and the borough is now operating the property. The company, according to the terms of the contract, had to sell if the borough decided to buy at the price set by the board, and although the price was less than that for which the stockholders were previously willing to sell the property, based perhaps on the earnings, it was not so much lower as to cause a great sacrifice. The company carried the plant value in its books at approximately $220,000, and the county court had, a few years previous to the award of the arbitrators, set the value, for ratemaking, of approximately $135,000.

In 1915, one period of 10 years having elapsed, the borough started proceedings, but these were objected to by the company, and after more than two years of struggle in the courts the arbitrators were finally appointed in the summer of 1917. The board consisted of Frederick P. Stearns, Boston; John M. Rice, Pittsburgh; E. W. Hess, Clearfield, Penn.; Fred C. Dunlap, Philadelphia, and Farley Gannett, Harrisburg. A detailed inventory was made by representatives of Mr. Rice and Mr. Gannett, working in the field together, and this was presented to the board sitting in Huntingdon, when unit prices were applied after inspection of the plant and the taking of some testimony.

The plant consists of a timber intake dam and brick pumping station, a reservoir and a filter plant, with the normal pipe lines, valves, hydrants, etc., for a town of 7500 population.

Extracts from Valuation Decision

The board was in session only 10 days, and handed down its decision on Jan. 28, 1918.

The following extracts are from the report of the board:

The schedule upon which the above valuation was based includes the real estate, buildings and other improvements, water rights, dam, intake basins, old pumping station and equipment, reservoir, filter plant, tanks, piping system, services, meters, fire hydrants, tools, supplies, equipment, office furniture and new filter-plant drawings. This schedule represents the property as of Sept. 1, 1917.

The schedule does not include the electric pumping station and its equipment, which are not included in the valuation, as the evidence presented to the board of arbitrators, including the contract between said water company and the electric company, dated July 20, 1907, indicates that this pumping station and its equipment are not owned by the Huntingdon Water Supply Company.

Guided Largely by Reproduction Cost

The board of arbitrators, in its determination of the value of the different parts of the water-works, has been guided largely by the cost of reproducing such parts, using as the unit prices for property, labor and materials the normal prices of recent years and not the abnormal prices which now prevail as a result of war conditions. No records could be found from which the original cost of the various property units constructed prior to 1900 could be ascertained, but for subsequent years records were available, and these have been used in many cases either to determine the cost or to aid in determining the reproduction cost of parts of the property added during and after 1900.

After determining the cost of the various parts of the property in active use as if they were new, a deduction has been made to cover the depreciation in value of each part, the intention being to make the amount of depreciation represent as nearly as practicable the actual loss of worth of the particular part resulting from the expiration of a part of its serviceable life, including the effects of wear and physical decay.

For parts of the property not in active use and no longer serviceable for future use, the salvage or scrap value has been allowed.

In determining in the first instance the cost of reproduction of the various property units, no allowance was made for contingencies or for omissions from the schedule, or for the overhead costs of promotion, organization, financing, administration and legal and engineering services. To cover these and other similar costs, a sum has been added to the previously determined cost of the real estate and plant.

In order to cover the additional cost incidental to the necessary use of money during the period when the works were under construction up to the beginning of their regular operation, a further sum has been added for interest during construction.

The total amount determined in the manner indicated has been adopted as representing the value of the water-works as a completed property ready for operation. A property of this sort requires still further expenditure in order to develop the business to the point where an adequate return is secured. Therefore, to the above total amount, a sum has been added to represent the increased value of the property as a going concern with a developed business and established earnings.

Several interesting points came up in the appraisal and are discussed briefly below:

Real Estate—The company owned a large tract of land, on a hill behind the town and extremely well situated for a reservoir. On a small part of this tract the distributing reservoir was built. The testimony showed that to have bought only so much of this land as was needed for the reservoir would have cost almost as much as the whole tract cost. Three real-estate dealers were engaged to value the real estate for the board of arbitrators, giving their opinion of the value of the property without regard to its value for water purposes, and to this value the board added what it deemed the proper amount for this use.

Filter Plant—A filter, built in 1900, but now seldom used, was treated as nearly obsolete but having some value by reason of the sale value of the machinery and equipment. Plans had been drawn covering a new mechanical filter plant, and allowance was made in the valuation for the cost of these plans.

Pumping Station—A steam pumping station and equipment of boilers and pumps were constructed at the time when the plant was built, but for several years had not been used, as the pumping was being done by electric pumping equipment. The new station and its electrical equipment were built by an electric company from which power was purchased. This contract provided that at the end of 10 years the pump station and equipment would become the property of the water company. This station was not included in the inventory or valuation, and the old steam station was included at a considerably depreciated value.

Going Value—A separate sum was added to the physical value to cover the "increased value of the property as a going concern with a developed business and established earnings." In this case the business was profitable, but had undoubtedly gone through a period in its early history during which for a few years the profits did not cover outlay and interest. As this plant was being purchased by a municipality, its value would not be subject to state regulation.

Speed and Cost of Proceedings

The arbitrators took their oaths of office July 24, 1917. The detail inventory was then made, the report was filed with the board of arbitration two months later, and by the end of January the value had been set. Compare this with the time consumed by the average rate-valuation case before a court or a public service commission. The writer has not been connected with a rate case before such a body which has taken less than 18 months for a decision to be reached, and then there often have followed appeals to superior and supreme courts.

The cost of the arbitration proceedings, exclusive of lawyers' fees to both sides, was only about 2½% of the value of the plant. This cost was charged equally to the borough and the water company in accordance with the terms of the contract, which also provided that if the borough had refused to buy the plant it would have had to pay the whole cost of the arbitration.

If, before throwing matters concerning water rates or valuation for purchase into courts and before public service commissions many of which are overloaded with work, the utilities and municipalities would agree to put these matters up to boards of arbitration composed of engineers they would, as a rule, get much quicker results, and I believe just as impartial results, and

at less cost. It is not the thought of the writer that boards of arbitration should replace courts and commissions in handling all such work, but it is a fact that, as more and more such work is disposed of thus, the strain on the judiciary and public service commissions will be lessened and prompter results obtained. Of course, where grave legal questions are involved, such matters would have to be solved by a legal body, but where simple matters of value only are involved the cumbersome machinery of courts or commissions is not essential, and results based on fairness and justice can be obtained by boards of arbitration promptly and inexpensively.

Another advantage of arbitration is that the decision is reached by men who are, usually, entirely familiar with the plant, meetings are held on the ground, and disputed questions can be settled by inspection of the article in dispute. A great deal of information and data can thus be obtained first-hand by the board or its members, and it does not become necessary to rely entirely upon often conflicting and prejudiced testimony.

An instance in point arose at Huntingdon. It was stated that a considerable amount of the pipe was laid in rock cut, and the board examined in a body certain sewer trenches then in process of excavation, as well as numerous test pits dug at selected points over the town, and made up its own mind concerning both the amount of rock excavation and the nature of it.

At another time, in order to settle certain questions relative to the class of cast-iron pipe used and its condition, a section of pipe which has been in use about 30 years was opened up and a section of it was cut, examined, weighed and measured by the arbitrators.

The practice of the Pennsylvania Public Service Commission is to order engineering conferences to be held between engineers representing the commission, the complainant and the respondent company. At these conferences the inventory is usually agreed upon, and often the complete reproduction value, less depreciation, and sometimes the historic cost. This conference of engineers reports its findings to the commission, and testimony is taken only on points not agreed to by the engineers. Often the operating expenses and rate of return have been agreed to at these conferences, as well as the segregation of the property between domestic and fire service. This is going a long step in the direction of decision by arbitration, but the trouble with this practice is that the commission's engineers cannot hand down decisions and must turn their results over to the commission, to await the long and tedious routine of procedure of testimony, argument and filing of briefs by attorneys.

Devastation Wrought by the Great War in Belgium, Serbia and Italy

By Major Daniel T. Pierce
American Red Cross, Paris, France

For the benefit of those contemplating professional work or business undertakings in the three countries named, concise reviews of the damage done and some of the general conditions prevailing have been prepared for "Engineering News-Record" by Mr. Pierce.—EDITOR.

Belgium: A Huge Total of Destruction

BELGIUM'S bill against Germany for damages has now been presented, at least in part. It does not include personal losses, which at the present time are being determined by tribunals throughout the country. These tribunals are open to the poorest householder, shopkeeper or farmer, and are making a record of every loss for which compensation is claimed, from a farm to a chicken. The statement is made on good authority, but not officially, that the personal losses, which include private structures of all kinds, the equipment of factories, etc., will equal the "state losses," the total of which, as submitted to the Reparations Committee of the Peace Conference, is \$3,000,000,000.

The total just mentioned includes an item of \$750,000,000 for damages and destruction of railways, posts and telegraphs. The other important items do not cover damage or devastation but refer to war expenditures (\$600,000,000), war taxes paid to Germany (\$500,000,000), the relief of the Belgian population (\$100,000,000), etc. Taking the situation as a whole, west of Brussels the Belgian railways may be described as in a state of chaos. At regular intervals there are deep holes in the right-of-way, with the rails twisted and standing upright in the air. Innumerable bridges and conduits have been blown up, and all sorts of structures, such as tanks, towers and stations, have been demolished. One of my informants, who asserts that he was an eye-witness, says that as the Germans retired they mounted a heavy gun with a deflected muzzle on a flat-car and this gun, as it was drawn over the lines, was fired into the receding track. I should say that this was merely a novelty in the general program, for it is evident that the greater number of the culverts and other vulnerable spots along the line were blown up from below. I am told that conferences are already under way between the Belgian Government and American firms with a view to arrangements for the reconstruction of the Belgian roads. An enormous amount of material and labor will be required to put them into operating condition.

Not only the railways but the roadways were in many places systematically destroyed, the most effective damage being done, of course, by demolishing bridges, but here and there it is evident that mines were exploded under the solid roadbed.

On the Belgian state railways, out of a total of 4150 km. of track, 1100 km. have been completely destroyed and 410 km. "rendered useless." Destruction is especially severe in the Borinage coal valley, in and around Tournai; in the vicinity of Bruges, Ghent, Courtrai and Ostend. The whole railroad system of west and east Flanders is classed as practically destroyed.

The great bridges over the Meuse at Liège, Namur,

Dinant and Anseremme, as well as the bridges leading in and out of Ostend and Bruges, are classified as a total loss. On the Ghent-Terneuzen canal eight bridges were destroyed, notably the two important structures at Selzeate near the Dutch frontier which weighed 3,000,000 lb. each. The total destruction in weight of bridges in Belgium totals approximately 100,000,000 pounds.

The block-signal system of the Belgian Government railways was entirely removed and replaced by a German signal system which is now useless, since the Belgian locomotive drivers cannot read the signals. Telegraph lines, telephone wires and all portable stores and materials were likewise removed or destroyed.

The Germans appropriated 2614 locomotives out of a total of 4593, or 57%. They also removed 9062 passenger coaches out of a total of 10,812, and made way with 80,568 freight cars out of a total of 94,737 owned by the Belgian railways at the time of the outbreak of the war. The actual value of material, cars and locomotives taken away, plus the damages to the Belgian railroads, is placed at $1,000,000,000. This does not include damages to interurban steam railroads owned by private companies which have not yet put in estimates of their losses.

A Huge Total of Destruction

The number of dwellings and other buildings destroyed in Belgium is officially stated to be 45,000. Of these 20,000 were wiped out in 1914 and the remaining 25,000 destroyed in the following years of the war. If, however, one considers only the buildings ruined, he will get a very misleading idea of what Belgian cities and innumerable small villages have suffered. Louvain, Dinant, Dixmude, Ypres, Termonde, Roulers—to name only a few of the larger places—together make up a huge total of destruction, while Bruges, for example, would add only a few to the list of ruined buildings. But more than 60 of the 83 famous bridges of Bruges were blown up in the last days of the war, and their destruction is a far more serious matter than the demolition of an equal number of houses.

There is also a vast although invisible loss in the deterioration of all public improvements, on which little or no maintenance work was done for more than four years. This is likewise the source of very serious damage to canals. The locks and sluices have been neglected and allowed to rot. Channels have filled up and, owing to continued neglect, it will take a long time to restore them to operating condition. This is also true of the Antwerp port facilities. At the present time this port is in shape to handle only about 60% of the pre-war tonnage. The lack of oil and of cable has led to serious deterioration of all hoisting machinery. Wood, on the other hand, seems to have been relatively plentiful. The Germans brought in quantities of lumber, and among other things that they did not have time to take away with them were several million feet of timber, about 10 x 10 in. in size, now stored in great piles near Bruges.

According to the Belgians, the Germans acknowledged that the value of raw materials and machinery moved from the country up to January, 1915, was $400,000,000, and according to a semi-official statement made by a Belgian official to a representative of the London *Times* the value of material and other equipment carried away by the Germans since that day would greatly exceed the sum stated. Not only were whole establishments robbed of every scrap of equipment, but the country was systematically looted of brass and bronze, even the smallest ornamental metal work being removed. In some hotels the brass door knobs and bolts were carried away, as was reported during the war. In the neighborhood of Liège, where there were a number of steel plants, the blast furnaces, mills and construction plants have been totally denuded of all heavy tools and equipment; even the bellows were taken.

In the mines the damage is not nearly so great as was expected, perhaps because, as is certainly true in some cases, the Germans were deterred from destruction by President Wilson's threat of reprisal if such destruction were attempted. Throughout the war the coal mines were systematically worked, but only to about 50% of their capacity. Apparently, only electric motors and cables were removed. The lifts and galleries of the mines are in good shape, but because of lack of oil and misuse of tools it will be necessary to replace about half of the machinery. The coal mine at Limbourg is the only one reported ruined by the admission of water. The cement industry, which was making good progress, has suffered very little. An expert who has made a survey of this industry states that all it needs to go ahead is belts and bags, which at the present time are unobtainable.

In the glass industry, where the production was important and profitable before the war, the plants have been reduced to about 50% capacity, and important repairs must be made before the industry can resume. The cutting tables were the only equipment carried away, for some reason. Considerable stocks of sheet glass were left, but no bottles.

The textile industry is another one that has not suffered severely by destruction or the removal of machinery. Very few weaving frames were taken, and Belgium's wool, cotton, hemp and flax plants could resume at present on a basis equivalent to 70% of the pre-war output—if raw materials were obtainable.

Agriculturally, Belgium has not suffered nearly so severely as France. Except for a comparatively limited area in the fighting zone, all of the lands heretofore devoted to farming could be put back under cultivation immediately. Here again there is the possibility of the resumption of normal industry defeated by lack of tractors, tools and transportation.

Almost No Horses Left in Belgium

There are practically no horses left in Belgium, which for centuries has produced the most valuable heavy draught horses in the world. These were systematically collected and carried away by the Germans. At a small town near Poperinghe last year I found a patriotic old Belgian doctor who had, by purchase in France, got together an Andennes stallion and six mares which were, he told me, all that were left of this famous breed. This, of course, was merely the exaggeration of despair, but, so far as being available for work purposes is concerned, the famous Belgian draught horse has, in fact, disappeared from the country. The Government has arranged to buy 25,000 Canadian horses and is endeavoring to buy 100,000 horses from England, presumably those that have been used for military transport. Of farm animals, cows and pigs, hardly a trace remains, and eggs even at the present time (February) are almost a curiosity in Brussels.

It would be more satisfying if it were possible to give an official estimate of actual destruction in Bel-

gium, but this, as in other countries, is impossible, because such figures as have been used in making up Belgium's bill for damages include enormous items for losses other than those that can be called damage to property. They even include losses due to the fact that the industries of the Belgian Congo have had to be abandoned. But after even a motor-made inspection of the destruction of towns, villages and isolated houses, factories, mines and plants, it is easy enough to believe the statement already mentioned that those Belgian losses classified as personal will equal, at least, the state loss of $3,000,000,000.

Wherever figures in dollars have been stated here they have been arrived at by counting five Belgian francs to the dollar.

Serbia: Transportation System Nearly Wiped Out

ALTHOUGH physical devastation in Serbia is bad enough, it is not so bad as the social devastation resulting from the movement back and forth over the country of three hostile armies during a period of more than four years. The population of about 5,000,000 has been reduced by more than 1,125,000, and, worse than this, the loss is mainly among the younger and more virile part of the population. This has an important bearing upon the subject of reconstruction, for with all men between 20 and 50 mobilized and those who have not been killed still in the army and most of them out of the country, no supply of labor worth considering is available. Furthermore, Serbia was not a land of artisans but of farmers, 85% of the population being engaged in agriculture.

Serbia is now reaching out for the aid of the United States in rebuilding the country, and it is for this reason that some facts in regard to conditions that prevail both in old and new Serbia are included here, although they do not relate strictly to devastation. One of the ministers of the new "Government of the Serbs, Croats and Slovenes" (which is the name by which the Government of Serbia prefers to be known), who was in Paris in February, was asked what America could do; what America could supply. His answer was, "Everything." The country is literally denuded of finished products, such as clothes, furniture, hardware, prepared woods, metals and glass.

And, to make matters worse, the finishing blow to the country's ruin was struck in October and November of last year, when its transportation system was almost completely wiped out. The main line of railway traverses the country from north to south, extending from Salonika on the Aegean Sea to Nish and Belgrade, with a branch line to Semendria. A through highway, poorly constructed, with many steep grades, parallels the railway. The main line of the railway from Belgrade to Nish continues through Pirot and on to Sofia in Bulgaria, forming a part of the "Berlin-Bagdad Railway."

This main line, as well as many of the branch lines, was destroyed by the Germans, Austrians and Bulgarians as they retreated through Serbia in the last weeks of the war. Bridges, large and small, and almost innumerable culverts were blown up. As the road parallels the Vardar and Morava rivers, it was carried over many smaller streams emptying into these rivers. These multiplied the number of bridges to hundreds, and all are destroyed. There were only three tunnels, but these also were destroyed. The roadbed itself was not disturbed except near Belgrade, where mines were systematically exploded every 1000 meters.

The main highway was just as systematically attacked, all bridges being mined. Originally, there appears to have been a stone base in the road, but this is now covered with a deep layer of mud in which the ruts are so deep that heavy camions find it almost impassable. On the highway, by Dec. 31 the bridges between Skoplie (Uskub) and Semendria had been temporarily repaired. A surveying party which made the trip between these two cities by camion was 11 days on the road. The only effort then being made to fill the holes and ruts was the employment in a desultory way of a few Bulgarian prisoners.

Thus, the two main arteries of Serbia's transportation system are virtually out of existence so far as supplying the needs of the country is concerned. The railroad has been repaired as far as Skoplie, and late in December a temporary bridge over the Vardar at Strumitza was opened. Two weeks later it was reported that trains were running to Kumanovo, and it was promised that by the end of February trains would run as far as Vranja, but as this would mean the rebuilding of a number of important bridges it hardly seems possible of accomplishment. From Kumanovo to Semendria and Belgrade not a wheel is moving on the railway except for about 12 miles south of Nish where the road had not only escaped destruction but where a locomotive in operating condition had been left. By January the Nish-Sofia line had been repaired from the Bulgarian frontier as far as Pirot, but no effort was being made to open it between Pirot and Nish. Efforts of the French and English to operate camion service between some of the important towns are defeated by the fact that the trucks cannot negotiate the roads. The camions used were chain-drive, and most of the time was spent in replacing chains. Trucks must be very lightly loaded and must carry their own gasoline, as no gasoline is to be had in Serbia north of Uskub. To complicate the transportation problem, especially in regions off the main line of highway, practically no horses or mules remain. Their skeletons are scattered by the roadside for almost the entire stretch of highway from north to south. Oxen are a little more plentiful in the north.

So desperate is Serbia's need that she has made an urgent appeal for details of the United States Army to take charge of the reconstruction of the main line of the Serbian railway.

Property and Population Records Destroyed

As for records, national or local, there are none. The Serbian officials who have returned to their posts find that the Austrians and Bulgars who assumed charge of the local governments destroyed or carried away everything, and when the Serbian prefects came back to their posts they found only empty buildings. There are no records of either property or population except fragmentary reports prepared by the Austrians for the purpose of rationing the country.

When the fortunes of the war changed last year it seemed to have been a surprise to the hostile armies occupying Serbia. They had sent home great quantities of food and furniture when the shortage in Austria and Germany became acute. Now they pillaged the country of everything that remained. Into Austria and Germany were transported carload after carload of

furniture, bedding and clothing, so that at the present time even those who were comparatively well off before the war have nothing but the clothes in which they were standing when the enemy departed. In this sense Serbia is devastated throughout.

But in the sense of physical destruction the devastation is confined to areas extending in strips along the northern and southern borders. In the north, along the Danube, the cities have suffered severely. About half the buildings of Belgrade are damaged, and of this proportion about 20% may be classified as destroyed. Important parts of Belgrade, the capital, were destroyed when it was originally captured by the Austrians in November, 1914, and again when it was captured by the Germans in November, 1915. Additional injury was inflicted when the Austrians and Germans departed in November, 1918. The industrial portions of the city suffered more than others. The largest tobacco factory is now only a crumbling ruin. Of the two largest hotels one is completely destroyed, and the other is in such bad shape as to require complete interior reconstruction. The royal palace is not habitable, and the University of Belgrade is seriously damaged. All over the city are buildings which, while they appear from the outside to be intact, are found, on closer inspection, to be gutted. Semendria, about 30 miles east of Belgrade on the Danube, is in much the same condition as the capital. Shabatz, 30 miles west of Belgrade on the Save, is in even worse condition.

Along the southern boundary of Serbia, which was the battlefront during the period of occupancy, there was, of course, serious destruction. Monastir, the second city in size in Serbia, was badly injured by shellfire. Officials estimate that 35% of all the buildings in Monastir have been so badly damaged as not to be repairable. A great many small villages in this area may be classed as wholly destroyed so far as providing human habitation is concerned.

Innumerable Buildings Blown Up

In addition to the destruction in the extreme northern and southern zones, there is sporadic destruction all over Serbia. The worst of this is found in the region on the line of retreat of the hostile armies. Innumerable buildings were blown up. The railroad station at Leskovatz, in central Serbia, a large structure, is now a mass of ruins. In other towns one is struck by the evidences of a practice of blowing out the windows and doors of the buildings facing on the principal streets, and those who have recently made a journey of 320 miles through Serbia by camion say that their most vivid impression is that of an avenue of doorless and windowless houses. No glass is obtainable in Serbia, and the practice has already been adopted of bricking up wall openings to within 6 or 8 in. of the top, depending only on such light and ventilation as may come through the door when left open or from the apertures at the top of what formerly were windows. Besides actual physical injury, hundreds of buildings have been rendered useless for a long time by indiscriminate disposal of filth and the use of structures of all kinds for stables.

The coal mines in Serbia, never a very important factor, are not operating now. There is wood, but no way of utilizing it. The fuel problem is therefore very serious, and the street railway in Belgrade in December and January repeatedly suspended operation for lack of fuel. The lighting plant was operated only for a few hours in the evening. Here again we have emphasized the fact that the key to Serbia's rehabilitation and the thing that must precede all efforts at reconstruction is the repair of her transportation system.

Most of the foregoing facts were taken from the report of the survey completed in January by Homer Folks, chief of the mission sent by the American Red Cross to inquire into post-war effects in the countries of southeastern Europe.

Italy: Physical Harm Unexpectedly Small

Unlike France, Italy has failed to keep systematic records of the destruction of public and private property by the enemy. It is impossible, therefore, in the case of Italy to present even the approximate figures that are available for France. Upon inquiry of representatives of the Italian Government attending the peace conference in Paris, it could be learned only that certain figures showing damage to Italian towns would be presented, but at the same time it was stated that these figures included consequential damages, loss of use, etc., making them valueless for the purpose of arriving at a determination of the actual damage to property suffered by the towns within the war area. But from several surveys that have been made it is possible to give a rather definite idea of the damage.

The actual destruction of buildings and other physical properties in Italy, while sufficient to give rise to a great social problem, is less than one would expect. The greater part of the fighting between the Austrian and Italian armies was in Austrian territory. It is to be considered, however, that this territory is now in the hands of the Italians and will presumably remain in their hands, so that whatever reconstruction problem exists will be one with which the Italian Government will have to deal. The area in which destruction was suffered is limited by the fact that in the invasion by the Austrian army of northeastern Italy, the Italian army opposed so slight a resistance until the Piave was reached that there was not much destruction by shellfire, and in the Austrian retirement there was likewise little resistance after the enemy had been driven from the river.

Physical destruction is, therefore, to be found almost wholly in three regions: Along the Piave, where the Austrian invasion was stopped and at which point occurred the heavy fighting in the final great invasion; in the Val Sugana above Bassano, and in Val Lagarina near the frontier. The Piave runs through one of the fertile and populous districts of northern Italy. Val Sugana and Val Lagarina are in the mountainous regions on the northwestern frontier of the province of Veneto.

While modern artillery carries for great distances, it appears that the area in which anything approaching total destruction of buildings occurs is limited to a very few miles. On the Piave, for instance, where the heaviest fighting occurred over a period of a year, there are many buildings standing yet, intact or only slightly damaged, up to within 5 km. of the river. But within this area of 5 km. on both sides of the river the greater number of the buildings are either destroyed or more or less damaged. Further away from the river this destruction is the exception, not the rule, although in certain cities more or less serious damage to buildings is found, especially where large numbers of troops were quartered, and those in which some

effort at resistance was made during the Austrian retreat. A notable instance of this latter condition is the town of Sacile, a village of a few thousand population about 25 km. from the Piave. In this town practically every house was damaged and a great many were destroyed. The Austrians made a stand here and also had used the village more or less as a headquarters for some time, in consequence of which it had suffered seriously from air raids as well as from bombardment.

At Pardenone, a city of 16,000 inhabitants, 10 km. further east, only a few destroyed buildings were found, but there were many of which only the walls and roofs remained, the doors and windows having been removed and in some instances even the partitions and floors torn out to provide fuel. The buildings occupied by the poor were much less damaged than the finer structures.

There are no large cities on the Piave, but there are numerous small towns ranging in population from 13,000 downward. Treviso, a city of 40,000, is some 15 miles west of the Piave, and was not injured by shellfire, though a good deal of damage was done in some quarters by bombing. It is officially estimated that 16% of the buildings are in some measure damaged.

As a whole, the province of Veneto may be classified as agricultural. A belt including the territory 5 km. on either side of the river would embrace a population of about 175,000. Within this area the destruction is not in all instances complete, but it is officially estimated that there are 200,000 persons in this belt and adjoining it whose homes were entirely destroyed. In addition to these, there are undoubtedly an equal number whose homes were considerably damaged, but not beyond repair. The homes of still others were looted of all furnishings, but the buildings remain intact.

No Comparison Between Italy and France

It would be a mistake to draw any comparison between Italy and the devastated agricultural regions of France. The region in which the land in Italy has been seriously injured from an agricultural standpoint by shellfire and trench operations has been very limited. Except along the lower Piave there are few shell holes in the fields or along the main roads, and a great majority of the trees along the road which crosses the Piave at Nevassa are still standing practically uninjured. The general appearance of this region is in marked contrast to such a region as the valley of the Somme, which was fought over repeatedly and in which all vestiges of permanent construction have disappeared. The land in the Somme is pitted in every direction, as far as the eye can see, with shell holes, and crossed by an interminable tangle of trenches and barbed wire. There is little vegetation. The difference is partly due to the fact that the Piave formed a natural barrier and the fighting was across that river, while it was along the Somme.

Very few refugees have returned to the devastated regions of Italy; this is due partly, no doubt, to the opposition of the military authorities. This opposition is very effective, because the Government controls all means of transport and there are only a few temporary bridges across the Piave. One judges from conversation with Italian authorities that the return of the refugees is not thought to be immediately desirable or necessary, and no program has been worked out, as in France, for even a gradual return of the former inhabitants. The Italian Government has considerable hesitation about entering upon temporary housing on a large scale. Its attitude in this respect is due to the rather curious fact that the temporary houses in southern Italy provided after the earthquake still remain in use, and no steps have been taken there for permanent construction. Meanwhile, the temporary housing has become extremely dilapidated and unsanitary. The people of the north are undoubtedly more progressive, but the Italian Government is evidently desirous of avoiding temporary housing if possible.

The occupied territory covering all of northeastern Italy, going west as far as the Piave River, inclusive of the Asiago plateau, forms about 5% of the total area of Italy and provided homes for 4% of the population. Almost 1,000,000 persons remained in the occupied territory, and their care at this time constitutes a much more urgent problem than does the rehabilitation of the devastated region. It is a problem complicated by the destruction of the railways, the damage to the roads, and the blowing up of all the bridges across the Piave River.

As in the case of all the regions devastated by war operations, in all countries, it is well to remember that the problem of physical reconstruction of buildings, while perhaps the most engaging, is also the most remote. The disturbance of soils and the wrecking of such water and sewerage systems as existed have the most serious results, as would be expected, and it is the dangers from such sources that must be first met. For example, the typhoid fever death rate in northern Italy, which had fallen from 27 per 1000 of population in 1911 to 19 in 1914, is now, on the basis of very imperfect statistics, placed at 26 and is probably much greater.

Decay of Timber in Mexican Low Coastal Plains

Inspection of Line of Southern Pacific Railroad in Mexico Showed Badly Decayed Condition of Untreated Pine

By J. D. Mathews

Engineer Maintenance of Way, Southern Pacific Railroad of Mexico, Empalme, Mexico

SAGGING trestles and rotted ties were found during the inspection of untreated pine construction on the Southern Pacific R.R. of Mexico, while redwood ties and cedar piling well withstood the same conditions of dampness in warm, moist coast lowlands. Six years is the probable life limit of untreated pine trestle timbering in this climate of the lowlands of Mexico, and redwood would be an immediate economy, as the replacement of pine ties and timbering would have to begin in two years after installation.

In December, 1918, the writer made a trip of inspection to investigate the physical condition of the unoperated portion of the Southern Pacific R.R. of Mexico lying south of the town of Acaponeta, in the state of Nayarit—a distance of about 103 miles. The operation of trains over this portion of the line had been discontinued by the railroad company in 1913 owing to the revolutionary disturbances, but the continuance of operation was attempted by the military authorities, until some time in 1913; since that time the line has been idle, with no attempt at operation.

This portion of the line was constructed between 1909 and 1912, reaching the City of Tepic with the close of December, 1911. The timbers in use in the

track and trestles are still those of the construction, and have had a service of from 7 to 9½ years. Portions of this line saw but a few months' operation, and none of it saw more than two years', with occasional use by the military authorities during the third. The present condition of the timber, then, represents one of decay only, destruction under traffic or mechanical wear not being a factor.

Pine timbers and, generally, sapwood of all timbers, decay very rapidly in the coastal plains of continental Mexico, bordering the Gulf of California, and particularly so south of Culiacan, the capital of the State of Sinaloa. Thirty or 40 in. of rainfall per annum causes the soils to remain damp a considerable portion of the year. This, coupled with a warm, moist atmosphere and associated with a jungle growth of grasses, underbrush and trees, and the whole soil covered with a tangle of vines, produces a condition that causes rapid destruction of those woods that do not contain, either naturally or artificially, a decay-resisting agent.

Untreated Pine Susceptible to Decay

Untreated pine is particularly susceptible to this decay, and more so when sawed as stringers, caps, ties and guardrail Creosoted pine, used in bulkheads, has suffered but little in the nine years since construction. Untreated pine, however, has rotted in various structures until trestles are sagging from their own weight, as they have not carried the weight of traffic for nearly five years. Thus, in the space of nine years, and absolutely uninfluenced by traffic loads for the past five years, a number of these trestles have rotted to destruction.

Decay attacks most readily the exposed end fibers, and traverses them longitudinally under a sun-baked shell of frequently respectable appearance. Ties that will crush under foot not infrequently present an almost perfect appearance, externally. Entering the end of the sticks, decay penetrates caps and stringers, sometimes but a few inches, but often for several feet, and, in cases, the entire piece is affected. Points of contact, also, are locations of proneness to decay. Stringers decayed at the ends and over the center caps are useless as such, although the major portion of the stick may be sound. Decay of stringers over the cap produces decay in the cap, if of untreated pine. If of redwood, however, the caps will be practically unaffected.

End panels of trestles have suffered more than the centers, but the centers have been far from immune. This is undoubtedly due to the fact that the end panels are in a more continuous state of dampness, being closer to the steaming earth, and also are more continually immersed in the shadows of the adjacent trees. The center panels are frequently over the tops of the trees and face the direct rays of the sun—always an enemy to the destroying microbe.

Nevertheless, while the timber in the center panels of the higher trestles will, undoubtedly, give the longest period of service, yet, in these lowlands the maximum length of life of untreated pine, under the best conditions, will probably not exceed 10 years, while by far the greater percentage will have disappeared in much less time. Such timber is seldom placed under more favorable operating conditions than as decking for our steel bridges, many of them on this line being 50 ft. or more above the water. Few of these structures have been in place more than eight years, and, with this length of service, under the best of conditions a heavy percentage of their ties and guardrail is completely gone.

Pine cross-ties have suffered most severely of all. Panel after panel of these ties is completely gone. This does not simply mean "have become unserviceable to the point of removal," but they have gone till the rails, over which no traffic has passed in five years, are crushing them down, or the tie has completely disintegrated—its place being marked by a mass of shapeless rot.

The lesson of the experiences is that untreated pine, in these warm, moist coast lowlands, will give but a few years of service. The pine cross-ties ceased presenting a condition for service an unknown period of time ago, as, long before they reached their present condition, they would have been unsuitable for operation. It is probable that three or four years under traffic would have been their average life. Likewise, trestle timbers had for the most part long since decayed beyond the point that would have sustained operation. As with the pine cross-ties, we have to look backward for the limit of time to which these trestles could have been operated in safety. Many of them passed this limit not less than two or three years ago, some of them more. It thus follows that six years will be the limit of life for much of this trestle timbering of pine, while but little of it will see a life of 10 years.

Redwood and Cedar Well Preserved

On the other hand, cedar piling, redwood caps and posts and redwood cross-ties stand out in strong contrast to the destruction of the pine. For the most part, cedar piling is only now approaching the point when renewals must begin. Redwood ties, in a number of actual counts of ties in track, when tested by picking and hammering with prospecting picks, showed up not more than 5 to 10% more or less doubtful cases of renewals required to the rail, under precisely the same conditions that caused such excessive decay in the pine.

It thus follows that redwood, displacing pine for cross-ties and trestle timbering in everything but stringers, will be not an ultimate economy but an immediate one, as renewals will begin in all replacements in pine in two years, and be continuous until the last stick will have been removed inside of eight years, while, with redwood, the evidence demonstrates a minimum of service of eight years, with an average and a maximum yet undetermined, but it is safe prophecy to state that it will be several years over the demonstrated minimum.

While the foregoing discussion is confined to the territory south of Acaponeta, yet the same conditions obtain on the operated line, with practically undiminished force, in the vicinity of the City of Culiacan. Further northward there is a noticeable reduction in this excessive decay, until north of the Fuerte River the decay approaches normal. This establishes the limits of the territory in which it will be an operating economy to substitute redwood for pine wherever mechanically possible as the State of Sinaloa and the lowlands of Nayarit. As we leave the lowlands and the elevation increases, approaching the City of Tepic, decay again begins to become normal. Just where the southern limit of excessive decay lies is yet to be determined.

High Relative Temperatures of Pavement Surfaces

Thermometer Readings Taken on Surfacings and on the Adjacent Lawns Show a Variation of from 9 to 22 Degrees

By G. S. Eaton

Assistant Division Engineer, Universal Portland Cement Company, Chicago, Ill.

Maximum temperatures of 124, 118 and 114° F. which were attained respectively by asphalt, brick and concrete pavement surfaces, according to observations made by engineers of the Universal Portland Cement Co., Aug. 6 and 7, 1918, were relatively high with respect to adjacent locations. From 11 a.m. to 6:30 p.m. the average readings for the three types of surfaces in the order named were 118, 113 and 108°. What the effect of such temperatures on rubber tires, horses' hoofs and shoe leather might be is questionable. It is well known that a great deal of tire trouble is experienced in hot weather because of the expansion of the air in pneumatic tires. Pavement surfaces at high temperatures would undoubtedly aggravate this condition.

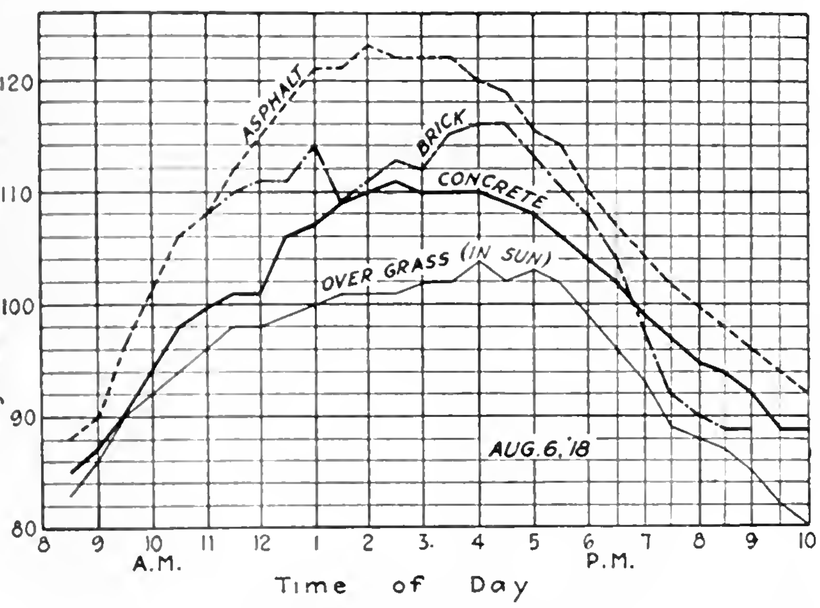


FIG. 1. SURFACE TEMPERATURES FOR VARIOUS TYPES OF SURFACING

During the middle of the day the effect of the pavements in heating the air above them was noticeable, as thermometers 1 ft. and 4 ft. above the roadways read from $3\frac{1}{2}$ to $4\frac{1}{2}$° higher than over a lawn in the sun. Temperatures above the pavements were found to be much the same, however, regardless of the type of surface. Over the asphalt, the readings averaged 1° higher than above the concrete, and $\frac{1}{2}$° higher than above the brick. After 7:30 p.m. the temperatures above the surfaces were practically the same as those of the surrounding air. The presence of large lawns and shade trees probably hastened the cooling and somewhat different results might be expected in the closely built-up sections of a city. Temperatures in the shade, 30 ft. away, were not influenced by the pavements.

The tests were made at Riverside, Ill., about 20 miles from Chicago. This place was far enough inland to escape the effect of lake breezes, and the three types of surfacing lay within a few hundred feet of one another. Absence of tall buildings and industrial plants with their accompanying smoke was another factor in the choice of location.

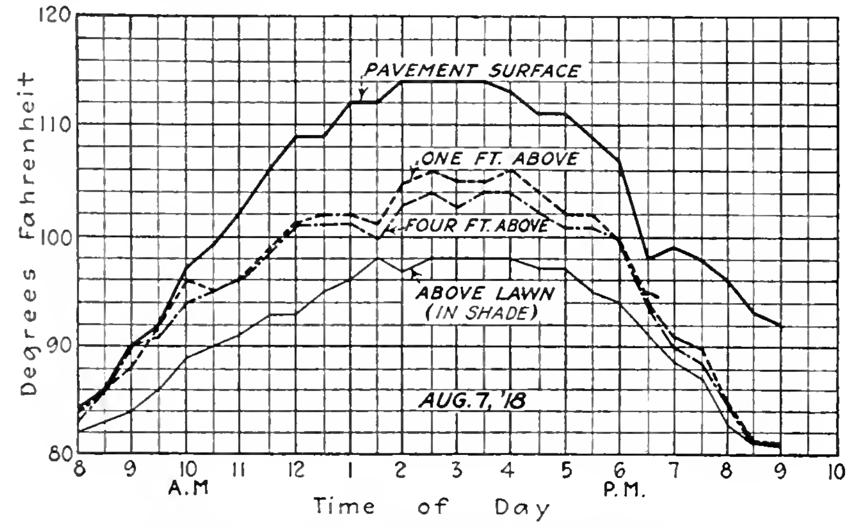

FIG. 2. VARIATION BETWEEN CONCRETE SURFACES AND VARIOUS ADJACENT LOCATIONS

Weather conditions were ideal during the period. The sky was almost entirely clear, and the maximum temperatures recorded for the two days by the Weather Bureau at Chicago were 102 and 101°—the highest of the summer.

For each pavement, readings were taken at the surface, 1 ft. and 4 ft. above, and 30 ft. to one side of the roadway in the shade above a lawn. An additional set of readings was taken 4 ft. over grass in the sun. Thirteen standard 25-cm. Fahrenheit thermometers were used, each protected from direct sunlight by a white paper or pasteboard cover. Readings were taken every half hour from 8 a.m. to 10 p.m.

At the pavement surface the thermometer bulb was placed in a small groove about 1 in. long, $\frac{3}{8}$ in. wide and $\frac{3}{8}$ in. deep. The groove was then filled with mercury to facilitate the transmission of heat between the pavement surface and the thermometer.

Figs. 1, 2 and 3 show graphically typical sets of readings plotted between temperatures as ordinates, and time of day as abscissas. Fig. 1 shows the difference between the various pavement surface temperatures and also the readings over a lawn in the sun. The drop in the brick temperature curve at 1:30 p.m. was due to the moving of the observation station on the brick pavement on account of the encroachment of shade. No point could be found on the brick surface that was in the sun for the entire day. The rapid drop in the same curve between 6:00 and 8:00 p.m.

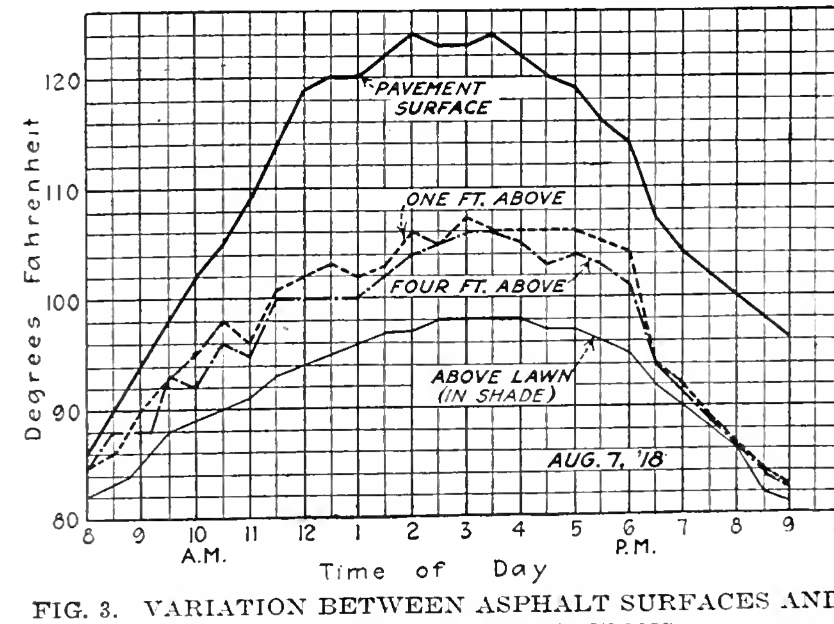

FIG. 3. VARIATION BETWEEN ASPHALT SURFACES AND VARIOUS ADJACENT LOCATIONS

was probably due to the proximity of the Des Plaines River, as air temperatures taken near by showed a similar drop.

Fig. 2 shows the relation, for a concrete pavement, between temperatures at the surafce, 1 ft. above, 4 ft. above and in the shade 30 ft. to one side of the roadway. Fig. 3 shows the same relations for the asphalt pavement.

LETTERS TO THE EDITOR

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Navy and Fleet Corporation Unfair to Their Own Draftsmen

Sir—In *Engineering News-Record*, Feb. 6, 1919, p. 298, I noticed a letter from Lloyd W. Weed commenting upon the wage award granted engineers in the Navy Department and the shipbuilding trades. He has quoted the War Labor Board's ruling of Oct. 1, 1918, effective immediately thereafter.

This explanation of what the Navy Department has done for engineers in general is absolutely wrong. The War Labor Board's awards were put into effect by the Emergency Fleet Corporation, and certain steel firms were forced to put in the rates under threats of cancellation of their contracts by the Secretary of the Navy.

The War Labor Board's rating was not put into effect in the Bureau of Yards and Docks and the different navy yards of the country. On Jan. 31 the Secretary of the Navy refused to make the awards retroactive to Oct. 1, 1918, and, also, the men of classes A, B and C, etc., were put in lower classes than their education and experience, of which an oath was taken, called for by the War Labor Board's ratings. This condition exists in general in the Bureau of Yards and Docks and the different navy yards. In addition to this, these increases in salary were made effective in the Bureau of Yards and Docks and in the navy yards about Feb. 5, 1919.

WILLIAM F. FOX.

Lawrence, Kan.

[Following the receipt of this letter and many others of the same purport, this journal addressed a letter to the Secretary of the Navy, asking for an official statement in the matter. The letter printed below was received in reply. From that and from information received from other sources, we are convinced that both the Navy Department and the Emergency Fleet Corporation have not followed the spirit of the Macy award with their own employees, but have applied it only to their contractors' employees. There seems to be no doubt, furthermore, that the Navy Department has resorted to the subterfuge of a reclassification to avoid the raising of wages among Navy draftsmen. Secretary Daniels' letter, dated Feb. 25, follows:—EDITOR.]

Sir—Referring to your letter of Feb. 19, 1919: Upon receipt of the award of the Shipbuilding Labor Adjustment Board (Macy board) on Oct. 29, 1918, the department, under date of Nov. 12, issued instructions to the navy yard service to submit recommendations for a readjustment in the pay of the drafting force, based on the above-mentioned award. Upon receipt of the recommendations, they were turned over to a board appointed within the department to analyze, reclassify if necessary, and submit final recommendation in each individual case. This board submitted its report to the department Jan. 17, 1919, and under date of Feb. 4, 1919, the department issued instructions to the several bureaus in the department concerned, and to the navy yard service, to make certain revisions in their original recommendations as to the readjustment in the pay of the drafting force recommended by said board, and to then immediately put into effect the increases.

It is believed at this time that the readjustment under the Shipbuilding Labor Adjustment Board award has been effected throughout the service.

JOSEPHUS DANIELS.
Secretary of the Navy.

Washington, D. C.

Letting Road Contracts in Long Stretches

Sir—I desire to express my approval of your editorial of Mar. 13, 1919, entitled "Letting Road Contracts in Long Stretches." The thoughts expressed bear out the conclusions I have drawn from a three-year intensive study of the methods of highway construction. The argument as it has come home to me runs about as follows:

The road building ahead of us is probably the biggest construction job that this country has ever had. The roads must be produced, not only in quantity, but quickly; and they must be built better than ever before. They must be *manufactured* as a standard product, as other commodities are manufactured.

Road building, from now on, must be considered an industry and, as such, will require large capital, large plants, large organizations and able men. The writer believes that the organizations, the capital and the men all will be forthcoming just as soon as the various states, counties and the Federal Government realize that the contracting must be done in a much bigger way than heretofore.

Contractors, in assembling their plants, have heretofore purchased individual *machines* instead of a coordinated group of machines that might be assembled into what we may call a *road-manufacturing* plant, where each machine is designed or selected as an integral part of the plant instead of an independent piece of apparatus. In the past one of the chief errors has been an unbalancing as among the capacities of the various elements of the plant. A mixer of large capacity, for example, has been idle for lack of material, due either to inadequate transportation facilities or to inadequate handling devices or storage at the receiving point. In other words, the plant has been unbalanced —uncoördinated.

It is a simple matter to lay out a plant that will enable the contractor to work his concrete mixers to capacity and to keep every one of the machines working efficiently, but that requires an investment of from $100,000 to $150,000. Such a plant will have a capacity of 15 to 20 miles per season. A road job five miles long, to be efficiently handled, however—handled so that each machine element works continuously at full capacity—will require the same amount of equipment.

The contractor should charge off at least 33⅓% of his investment per annum, to take care of depreciation, interest and repairs. In other words, a fully equipped contractor has a plant overhead to carry of $35,000 to $50,000 per annum. It is not reasonable to charge this against a few miles of road. It should be charged against just as many miles as it is possible for that plant to turn out in a full season's work. With a contract for only five miles of road, however, the contractor needs to procure at least two, and perhaps three, more contracts during a season in order to be successful. But if he were given one contract for 15 or 20 miles of continuous road, he would not suffer the delay of moving the plant from one job to another, nor delays in procuring additional contracts. His entire thought and energy would be concentrated on one job.

Contractors, in an endeavor to hold down their investments, instead of purchasing a complete plant, often sublet parts of the work. But the investment in equipment is there just the same, and *somebody must pay for it.*

Another element favoring the large, coördinated plant lies in the fact that there is no branch of construction work that can be so nearly standardized as road building. The building of one mile of road of any kind cannot differ much from the building of any other mile of the same kind of road. The plant is a standard one; no fear that it must be disposed of when one job is finished, for it can be used just as economically on the next job. In this, road plants differ from the plants required for the construction of buildings, bridges, dams and other classes of work which must be planned differently each time to meet special conditions.

Again, a desirable class of workers soon to be available may best be employed in handling plant, rather than in doing manual work. It has been urged that road building should immediately go forward to give employment to the men of our returning armies. It is submitted, however, that our boys are not coming home with any idea of doing pick-and-shovel or wheelbarrow work. The days of hod carrying are over. These men have been highly trained in organization and coöperation. The war has been won largely by machinery, and our armies have been trained to handle and to care for that machinery.

Even if a soldier were a common laborer before he went away, he is coming home with a broader vision of things, with more ambition, a better education and a desire—even a demand—for a better class of employment than he left behind. In short, the men returning from abroad will be exactly the sort of men that we shall need in a large contracting organization, handling large machinery installations.

Furthermore, common labor is becoming ever scarcer and more uncertain. Fortunately, well designed plants require comparatively few men, and may be expected to go far toward stabilizing the road-building industry by improving the class of labor employed and reducing the labor turnover.

On the other hand, because it is impossible to use properly coördinated plants on the short sections in which the work has been let in the past, the present price of hard-paved roads undoubtedly is higher than it should be. Ultimately, the use of proper plants will reduce the cost of the roads, just as large factories, running on quantity production, reduce the cost of any other commodity.

When engineers and contractors come to realize the possibilities of well coördinated plants, they undoubtedly will plan their work accordingly. Contracts will be let earlier, so that construction may start as soon as the frost is out of the ground in the spring. Contracts will be for longer stretches of road, so that the plant will continue in operation until stopped by bad weather in the fall.

Road building on a large scale is undoubtedly a business to engage the attention of large capital and capable organizations. Let those engineers who have a large mileage of roads to build award the contracts for a few large sections, rather than for a number of short sections as in the past, and there is no doubt that more of the contractors who have been engaged in big work along other lines will be attracted to the new field.

Would Use French as International Language for Engineers

Sir—I have read with much interest the letter in your issue of Feb. 27, p. 442 entitled "International Language for Modern Engineers," as well as certain other articles on technical publicity. Either of these subjects alone is of the greatest importance to the modern engineer and the engineering profession, but they are at bottom really closely inter-related, as the latter can be realized or obtained in its most comprehensive and broadest scope only through the former.

The writer of the article referred to seems to possess a full realization of the importance of an international language for modern engineers, but, as he says, is probably too prejudiced, on account of his position as chairman of the propaganda committee of the Esperanto Association of North America.

The necessity of technical publicity is being more and more fully realized every day. As a result we have the recent remarkable advance in the growth and activities of local societies. Also, as noted in your issue of Feb. 27, p. 439, a leading consulting civil engineer, L. P. Wolff, proposed that the American Society should set aside $10,000 annually for publicity work; $50,000 to be paid to five writers to furnish engineering articles for the daily and Sunday papers, the balance for expenses of inaugurating and maintaining the work.

Why not adopt French as the international language? It seems the logical one. Already it is the international diplomatic tongue—why not the international engineering tongue? Not only is it the easiest to learn, but, in addition, the majority of engineers already have a good foundation in French or in Latin—which is very similar to French—or perhaps in both, as both these languages are in the curricula of most high and preparatory schools and engineering courses of most technical institutions and universities. To cite my own case as a typical example—in private school it was ordained that I study both French and Latin as a necessary preparation for whatever might follow; in high school both were in the curriculum and had to be pursued; at college it was a choice among French, Spanish and German in the department of civil engineering, French

being by far the choice of the largest number; and, lastly, at the Military Academy at West Point French was compulsory.

One requisite in obtaining publicity is very aptly expressed in an editorial in the issue referred to above (Feb. 27), p. 407, entitled, "How to Get Local Publicity." It is this: "In the last analysis actual flesh-and-blood contact must be made. The more human it is the better the result." This is a true premise, and the logical deduction is that the best way to get widespread or international publicity is through the French language, the language of the country which is the very soul of the "flesh-and-blood contact" of nations today. France exerts a powerful influence over the minds and lives of millions of men of many different nations who have fought on her soil. The French language already has a big impetus in other countries through the words and phrases of everyday life brought back by returning soldiers and perpetuated in songs and poems both on and off the stage.

Furthermore, tendencies seem to indicate a further growth in the study and teaching of the French language in the future. I hope that every one interested in the use or adoption of an international language for engineers will seriously consider the advantages and merits of the French language.

Second Lieutenant, Corps of Engineers, United States Army.
Camp A. A. Humphreys, Virginia.

Defines Right-Hand Door and Comments on Concrete Floor Finish

Sir—I read Mr. Conrad's letter in your issue of Jan. 23, 1919, p. 201, on how to determine the hand of a door, and thought that it would be answered quickly and in a practical manner. However, there has been so much delay in answering the question, and the one given in your issue of Mar. 6, p. 485, is so unsatisfactory, that I am going to give my definition of a right- and left-hand door. I hesitate somewhat to write to your paper, inasmuch as I am a member of the B. M. & P. I. U., and also because I read in a recent issue of your paper that the "outstanding characteristic of union labor is selfishness"—which goes rather against the grain.

Place yourself squarely in front of the door of the room you are about to enter. If the door swings around to the left and away from you it is a left-hand door. If the door swings around to the right away from you it is a right-hand door. If the door opens toward you and then swings to the left it is a left-hand reverse; if the door opens toward you and swings to the right it is a right-hand reverse. A left-hand door and a right-hand reverse door describe the same thing.

The writer has had charge of several structures and at no time has he failed to compare correctly in respect to the hand of doors when listing hardware for the interior trim of a building. I trust this explanation will be sufficiently lucid to aid Mr. Conrad in his perplexity.

The article by William McGinnis in the issue of Mar. 6, p. 477, was hardly a finished treatise on cement finish. I refer to the article as a whole, but in particular to the indefiniteness of the treatment of the concrete with acid. No mention was made of the thorough removal of this necessary before the application of grout and cement—or was it taken for granted? One of the most difficult things to do in concrete work is to apply cement finish on a concrete sub-base that has been placed for some days. I do not take exception to the method of screeding described, but do believe the proper amount of detail was omitted.

THOMAS P. MORRISSEY.
Springfield, Mass.

Some Additional Approximate Formulas for Structural Work

Sir—In your issue of Mar. 13, 1919, p. 534, you published an interesting article entitled "Approximate Formulas Useful in Structural Design," by R. Fleming. The following formulas, similar in character to those in Mr. Fleming's article, have been very useful and I send them to you in the hope that they may prove helpful to other engineers.

Approximate Weight of Angles—Multiply the sum of the widths of the legs in inches by the thickness in thirty-seconds of an inch. Divide the result by 10. Thus, for a 4 x 3 x $\frac{3}{8}$-in. angle, $(4 + 3)\ 12 = 84$. The weight in pounds per foot is 8.4.

Approximate Strength of Crane Chain, Safety Factor 4—Square the size of chain in eighths of an inch. Divide the result by 10. The answer will be in tons. For example, a three-quarter chain is six-eighths thick, and $6 \times 6 = 36$. The chain is capable of carrying 3.6 tons.

Resisting Moment of a Row of Rivets About Its Center of Gravity—Number each rivet consecutively, beginning with 1. Add these numbers together and multiply by the stress S on the outermost rivet. If the spacing of rivets is 3 in., the product will give accurately the moment of the row. For any other uniform spacing, divide by 3 and multiply by the given spacing. Thus, for a row of five rivets, spaced 4 in. on centers, and having the outer rivet stressed to 2000 lb., the moment in inch-pounds is

$$(1 + 2 + 3 + 4 + 5) \times \frac{4}{3} \times 2000 =$$

40,000 inch-pounds.

HARRY K. ELLIS,
Assistant Engineer, Bureau of Highways.
Philadelphia, Penn.

Wages Small Part of Ship-Operating Cost

According to J. H. Rosseter, director of operations, United States Shipping Board, there is an entirely wrong impression abroad regarding the effect of high wages for seamen on the cost of operating American ships. As is well known, United States laws require a higher wage scale on ships under American registry than do the laws of any other country. Mr. Rosseter, however, points out that under conditions now prevailing wages constitute only 7% of all ship-operating costs, so that a large percentage of increase in wages will have only a small effect on total operations. He stated that at present it costs $500,000 more to construct a 10,000-ton cargo carrier on this side of the Atlantic than on the other side. In this case, the American-built steamer has a capital charge of $6500 per month more than the European-built vessel, whereas the total wage cost of operating the boat is only $4000 a month.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Concrete Under External Hydrostatic Pressure Made Water-Tight

IN BUILDING a sump and pump chamber in the subway tunnel under the East River in New York, a successful method of making water-tight the concrete walls, that were under an external hydrostatic pressure, was used. It was necessary to construct the sump outside the cast-iron tube, and air had to be used. The concrete was placed under a pressure of about 11 lb., and when the air was taken off it was found that the pressure had made the concrete so porous that under atmospheric pressure the water in places came through in fine needle streams. After discussing several methods of waterproofing, it was decided to try out a simple expedient at first. If this had not been successful a more elaborate process would have been necessary. The chamber was again put under air pressure. The walls of the chamber were then liberally swabbed or painted with a thick grout mixed of the consistency of about one bag of cement to half a bucket of water. The air pressure forced the grout into the holes and closed them up. The air was again reduced to normal and places were noted through which the water still leaked. These were marked and later the pressure was again put on, the holes being fed with the grout until they were completely stopped up. When the pressure was again reduced to normal it was found that the process was entirely successful and the chamber was as dry as a bone.

Other Articles in This Issue of Interest to Contractors

Tests of Frozen Rope Indicate Slight Loss of Strength

A RECENT test indicates that being frozen does not, as has been generally believed, greatly lessen the breaking strength of fiber rope. Four specimens were cut from a 3-in. manila rope. All were spliced at each end with an 8-in. splice. The length between the splices was 6 ft. Two specimens were soaked in water for 45 min., then exposed to an 18° temperature from 5:30 p.m. to 9:30 a.m. Both were stiff with frost when tested. The other two specimens were kept unfrozen. Elongation, at 50%, 1¾ in., and at 80%, 2 in., was the same in all specimens. The breaking strains were, for the frozen rope 10,000 lb. and 10,900 lb., and for the unfrozen rope 11,000 lb., and 11,300 pounds.

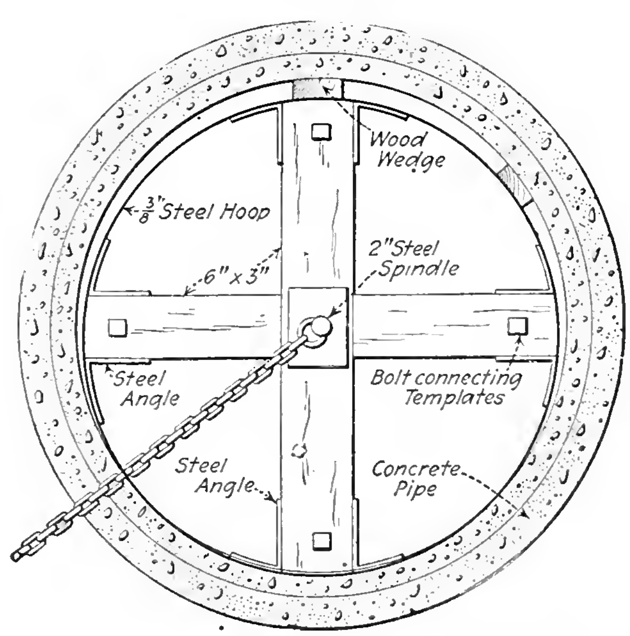
This experiment was conducted by Fred A. Jenks, Plymouth Cordage Co., Plymouth, Mass., to answer an inquiry by the editor. Mr. Jenks comments as follows:

"The results were rather surprising. It was expected that the unfrozen rope would show a much larger breaking strain, comparatively. As soon, however, as pull began to be exerted on the frozen rope the frost particles began to break up. After the rope had broken, the portion under stress was absolutely clear of frost, although in the splices, where the strain was on the double, the rope was still somewhat stiff from frost, and the ends of the tucks were completely frozen. Between pulling centers there was practically only a damp rope at the time of rupture. The pull had not only broken the frost crystals, but the heat generated by the friction in the strain and breaking of the rope had melted the frost. However, despite the showing made by the tests, everyone who has handled frozen rope knows that it cannot be as easily handled or run as freely over sheaves or used as well over capstans, and that it is much more difficult to secure. These facts alone constitute good reasons for protecting rope from frost."

Concrete Sewer Pipe Transported by Rolling to Place

By L. McLaren Hunter
Ottawa, Canada

IN THE construction of the Rideau Interceptor, the work of conveying the concrete pipe from the point where the pipe contractors had dumped them caused



ROLLING SOLVED PROBLEM OF TRANSPORTING PIPE

delays and entailed great expense. At first a track was built and a light carriage made. This was drawn by a horse to the derrick, but the lifting and laying of track always delayed the work of pipe laying for several days.

The difficulty was overcome by providing two templets, as shown by sketch, which were inserted in the pipe, each section of which averaged 3700 lb., and tightened by wooden wedges. Through the center was a 2-in. steel spindle which protruded about 9 in. at each end.

A team was hitched to this and the pipe was drawn to the job like a large roller. With this device there were no delays in pipe laying.

Care was taken to see that the pipe met no obstructions on the path, and apparently they suffered no damage by the operation.

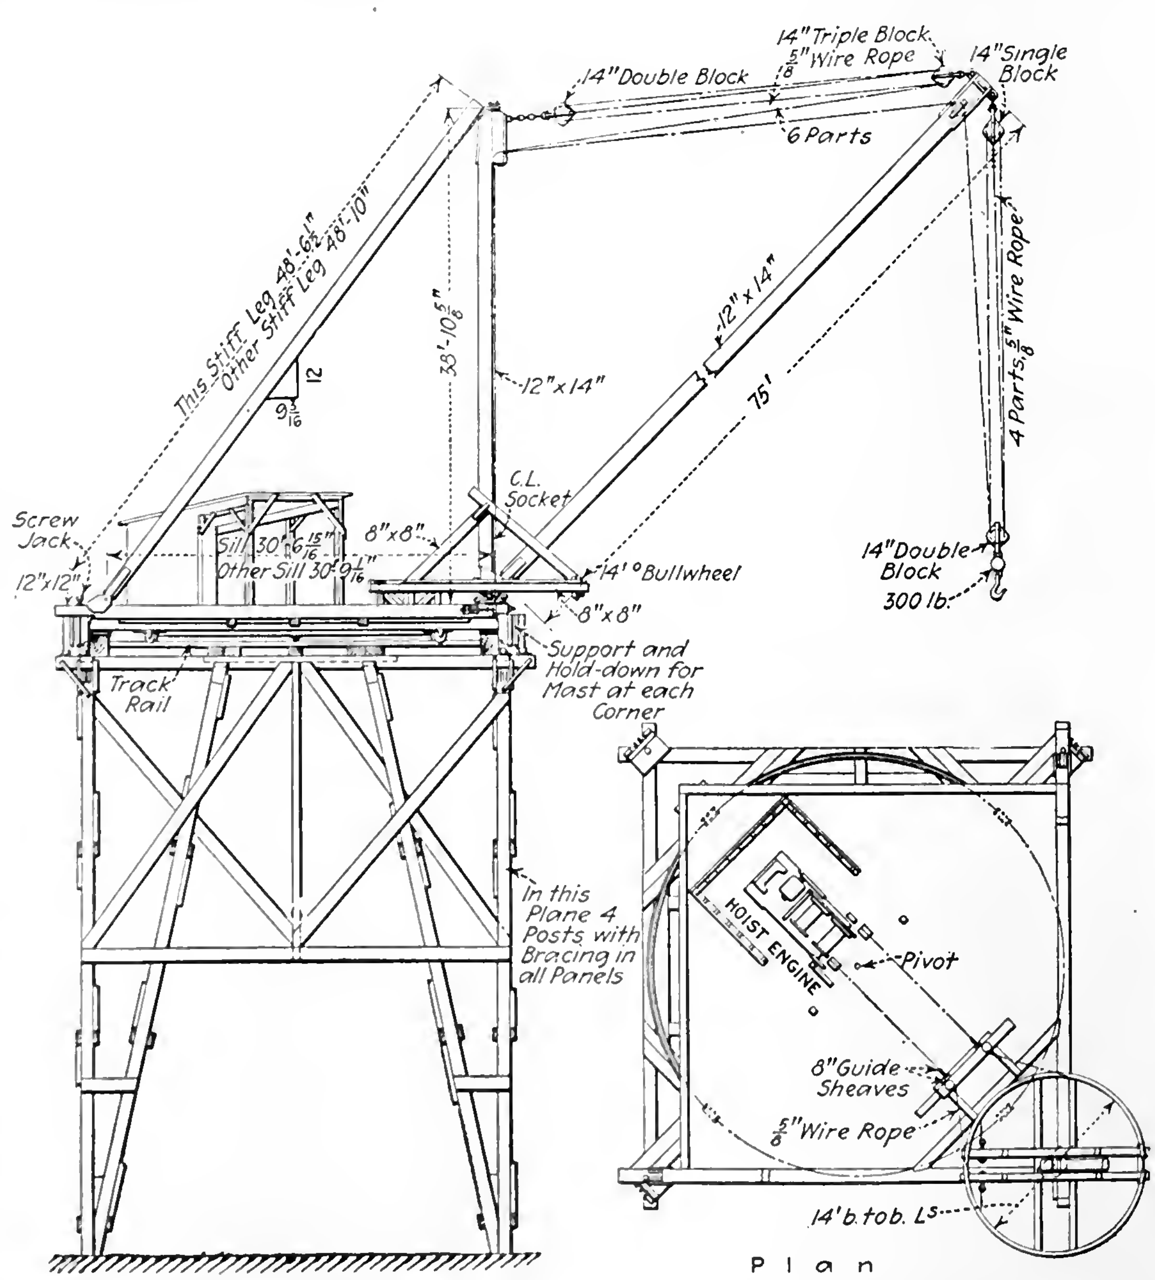
Turntable Mounting Extends Reach of Stiffleg Derricks

TOWER derricks used by the Foundation Co. in its New Orleans shipyard have an ingenious turntable mounting, by which a derrick of given length of boom commands a larger area. It is shown by the drawing.

The derricks themselves are standard machines made by the Edward F. Terry Mfg. Co. They are set on wooden towers 32 ft. square, ranging from 35 to 48 ft. in height, in order to bring the derrick step above the deck level of the ship; the 48-ft. towers are near the head of the ways where the ship is highest above ground. The derricks have a capacity of five tons at 75-ft. radius, or 15 tons at 45- ft. radius. A timber base frame carries mast, stifflegs and engine. This frame bears through four wheels on a circular track rail resting on the tower top, and the derrick can thus be turned to face in any direction. The mast of the derrick centers over any one of the corner posts of the tower, when the frame is swung to proper position. On top of each of the four posts is a heavy bearing block, steel shod, and the mast can be brought to bear on this block by means of a screw jack fastened in the derrick base frame. Two other screw jacks at the rear ends of the sills transmit any uplift to the tower posts. A steel hook-shaped fitting attached to each bearing block projects inward over the the turntable and prevents its lifting.

By turning down the screw jack into a socket in the top of the bearing block, the mast is given firm support and the turntable locked in position.

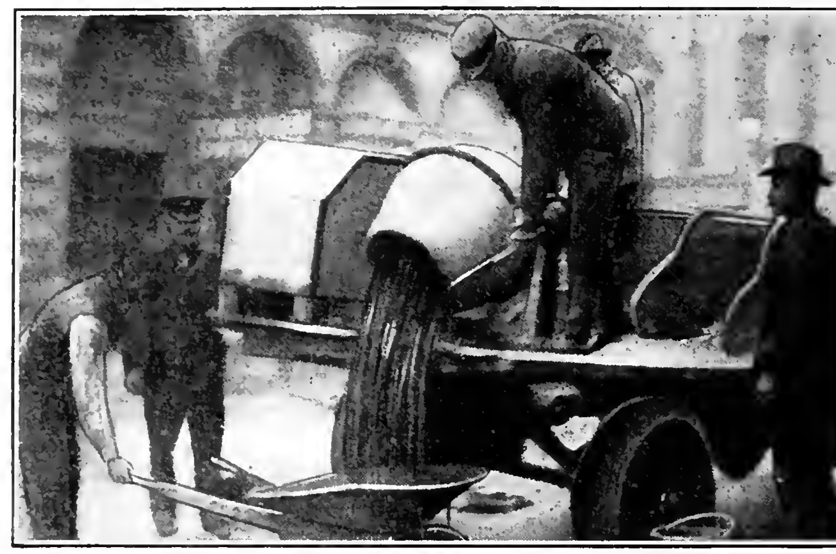
The derricks at the New Orleans yard have 75-ft. booms, but through the arrangement described they are enabled to command an area of about 100 ft. in radius.



TOWER DERRICK WITH TURNTABLE MOUNTING HAS 100-FOOT EFFECTIVE REACH WITH 75-FOOT BOOM

Mixer Mounted on Street Repair Truck

TO HANDLE the concrete work of small street-repair jobs, the City of New Orleans had a 1½-ft. mixer mounted on a 3-ton truck on which material bins of 1-yd. total capacity are also built. This leaves space enough to carry the necessary cement, which is



USING NEW ORLEANS' TRUCK-MOUNTED MIXER

often piled against the open end of the bins to increase their capacity. One man standing on the truck places the stone, sand, cement, and the water in the mixer, which he dumps over the end of the truck as each batch is mixed. The outfit is owned by the Department of Public Property.

NEWS OF THE WEEK

New York, March 27, 1919

American Society Convention to Be Held June 17-20

The annual convention of the American Society of Civil Engineers will be held this year in St. Paul-Minneapolis June 17-20, according to decision by the Board of Direction. The last June convention was held in Pittsburgh in 1916, the St. Paul-Minneapolis meeting scheduled for June 12-15, 1917, having been indefinitely postponed on account of war conditions.

The committee of the board in charge of arrangements consists of W. L. Darling, E. E. Wall and Charles Warren Hunt. The local convention committee consists of the following members: W. C. Armstrong, Frederic H. Bass, R. B. C. Bement, F. W. Cappelen, Oscar Claussen, William de la Barre, F. E. House, W. H. Hoyt, W. N. Jones, F. C. Shenehon, Horace E. Stevens, Howard E. Stevens, P. E. Thian, W. T. Walker, George L. Wilson, L. P. Wolff, R. D. Thomas.

Railroad Construction Work Stopped

By order of the Railroad Administration, all new railroad work in the way of betterments, additions or new lines will be held up, owing to the failure of Congress to provide the necessary funds. Only such construction is to go ahead as is necessary to insure safety or to protect contracts already entered into.

National Chamber Urges Private Aid to Employment Work

In connection with the recent appeal of the United States Employment Service, that communities and business interests carry on the work, as far as possible, until such time as adequate funds may be provided by Congress, the National Chamber of Commerce of the United States has issued a call to commercial organizations of the country, urging them to assist in every way possible in placing returning soldiers and sailors in employment.

War Department Will Receive Bids on Cantonments April 15

Bids will be received Apr. 15 for Army camp material, including buildings, railroad tracks and sewerage systems, to be abandoned by the War Department. The plan is to sell entire camps for lump sums, and big industrial concerns are regarded as the most likely purchasers. In some cases, state governments are expected to bid for the camps for use as National Guard training centers. Such bids will have preference.

Thirteen camps to be sold on Apr. 15 include all the War Department has definitely decided to dispose of. Others may be sold later. The 13 are: Camp Beauregard, Louisiana; Bowie, Texas; Colt, Pennsylvania; Hancock, Georgia; Kendrick, New Jersey; Logan, Texas; Polk, North Carolina; Sevier, South Carolina; North Camp Jackson, South Carolina; Shelby, Mississippi; Sheridan, Alabama; Wadsworth, South Carolina, and Wheeler, Georgia.

Division storehouses and the utilities serving the storehouse area are excepted from sale.

Tentative bids have been received from the State of Louisiana for Camp Beauregard and from Alabama for Camp Sheridan, the expressed intention in each case being to utilize the sites for the mobilization of state troops in case of emergency.

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Engineering Societies Employment Bureau; secretary, 29 West 39th St., New York City.

American Association of Engineers, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Engineers' Service Bureau, maintained by the Joint Council of Engineering Societies of San Francisco, Engineers' Club, 57 Post St., San Francisco. Only applications by mail or wire will be considered.

In the general cut in the United States Employment Service it has been found necessary, officially, to abolish the offices of the Professional and Special Section, but it is hoped that this work may be continued by local interests. As mentioned in these pages last week, the Military Training Camps Association at Chicago has already taken over the work of the Professional and Special Section office in that city.

Engineers Discuss Plans for Vehicular Tunnel

Size and Design of Proposed Hudson River Tube are Unprecedented and Suggest Many Difficulties

Plans for the proposed vehicular tunnel under the Hudson River at New York City were discussed at a meeting of the American Society of Civil Engineers Mar. 19. The society has seldom held a session at which greater interest was manifested. While several different designs were described, the main interest centered around the one adopted over a year ago by the New York and New Jersey Bridge and Tunnel Commission. Arguments both for and against this design were advanced, and the great number of uncertain conditions to be met, due to the unprecedented size of the tube and of the shield to be used, were brought out by expert tunnel men. The state Reconstruction Commission, to which Governor Smith of New York is referring such projects, assisted by an advisory committee of engineers nominated by the Engineering Council, had held a public hearing on the project Mar. 12 and several of the engineer committee were present at the meeting of the society Mar. 19.

The plans, which were adopted by the tunnel commission, are for a tunnel 42 ft. in diameter, to be built according to novel methods originated and patented by John F. O'Rourke. As described by Mr. O'Rourke in *Engineering News-Record* of Mar. 21, 1918, p. 563, the tunnel is to be driven with a shield having its face divided by horizontal partitions into separate compartments in which different pressures of compressed air are carried, according to the hydrostatic pressure in the earth penetrated. The tunnel is to be lined with precast concrete blocks instead of cast-iron segments, and is to have the space back of the shield filled with gravel blown in by compressed air, instead of the usual grout filling. The O'Rourke plans have been approved by Gen. George W. Goethals, consulting engineer to the New York and New Jersey Bridge and Tunnel Commission.

Some of the questions which must be settled before the practicability of the large-diameter tunnel can be affirmed were stated by Paul G. Brown in his remarks at the Civil Engineers' meeting as follows:

Can a tunnel such as this proposed be ventilated?

Can a shield 43 ft. in diameter be constructed of sufficient strength without prohibitive weight and expense?

Would premolded concrete blocks

have sufficient strength to withstand the thrust of such a shield?

Could premolded concrete blocks of the design suggested be made water-tight?

Would premolded blocks of the design suggested have sufficient strength to support the tunnel structure?

Is it possible to maintain compressed air of several stages of pressure in the face of a shield?

Can a shield of such size and length be kept to line and grade?

It is a well known fact that a shield, if it cannot move ahead, will move downward, and if such a shield did settle, could it ever be brought up to grade again with the projection of the lower part acting as a cantilever?

This shield is 93 ft. below mean low tide or 20 ft. lower than would be necessary with a smaller tunnel with correspondingly lower air pressure. In the bottom chamber through the rock section the "sand hogs" would only work short hours. The shield could move no faster than the bottom chamber. Would this make the progress so slow that the cost would be prohibitive?

Can any system of concrete blocks be designed for the North River that would be a proper substitute for the usual cast-iron lining?

Would the congestion of traffic at the terminals due to the concentration into one tube prohibit that type of construction?

Would two single tubes, if carrying two lines of traffic in each direction, be sufficient for the present traffic needs?

What units of cost are used in making the estimate of $11,500,000 for this tunnel?

The discussion was notable for the number of well known engineers experienced in soft-ground tunnels who participated, including J. Vipond Davies, James Forgie, W. C. Parmley, A. F. Byrne and Fred Lavis. Replies to various criticisms of the tunnel design were made by John F. O'Rourke.

The engineers advising the Governor's reconstruction commission have recommended that the whole matter of the designs and estimates for the Hudson River vehicle tunnel should be referred to a board of engineers to investigate and report as to the best plan.

Kansas City Cannot Make Ice

A proposed $400,000 bond issue to provide money for a municipal ice plant for Kansas City, Mo., has been declared unconstitutional by the Supreme Court of the state on the ground that ice-making is a private enterprise and the city cannot engage in private enterprises. The decision was six to one. The dissenting judge held that ice is a prime necessity in cities and its manufacture for the protection of the health of the people is an exercise of the police power. There is said to be talk of an application for a rehearing. E. M. Harber is city counselor of Kansas City.

New President of American Railway Engineering Association

Earl Stimson, elected president of the American Railway Engineering Association at the annual meeting last week in Chicago, was appointed, in August last year, general superintendent maintenance of way and structures of lines under the jurisdiction of the Federal manager of the Baltimore & Ohio R.R. Lines East. He received his technical training at the University of

EARL STIMSON

Cincinnati and at Cornell University. In 1895 he entered the service of the Baltimore & Ohio R.R. as a rodman. His service has been with the Baltimore & Ohio and affiliated lines ever since.

In 1898 he was made assistant division engineer at Chillicothe, Ohio, and in 1901 division engineer at Flora, Ill. Four years later he was appointed engineer maintenance of way of the Baltimore & Ohio Southwestern R.R., with headquarters in Cincinnati. In 1910 he went to Baltimore as chief engineer maintenance of way of the Baltimore and Ohio R.R., succeeding A. W. Thompson, who became chief engineer and who lately resigned as Federal manager of the Baltimore & Ohio and associated lines to become president of the Philadelphia Co., Pittsburgh. On Aug. 1, 1918, Mr. Stimson was appointed general superintendent maintenance of way and structures of the Baltimore & Ohio Lines East.

Canadian Budget Provides For Public Work

The estimates for the financial year 1919-20 were presented to the Canadian House of Commons last week. They included unusually large appropriations for railways and public works. Estimated expenditure on capital account by the Department of Railways and Canals was $50,896,681, including the following items: Construction of and betterments to the Canadian Government Railways, $11,121,681; railway equipment and materials, $35,000,000; Port Nelson terminals of Hudson Bay Ry., $100,000; construction of Welland Ship Canal, $3,500,000; and construction and betterments of the Trent Canal, $1,000,000. There are also appropriations of $30,000,000 for the Government's shipbuilding program, and $348,930 for harbors and rivers in Ontario. A grant of $10,000 is made to the Canadian Engineering Standards Association for the promotion of uniformity of standards in metals and their products.

Hurley Reports Shipping Statistics

Chairman E. N. Hurley of the United States Shipping Board has released his report on a three months' visit which he has just completed in Europe, investigating the present conditions in the shipping industry of the world. It contains few facts or promises for the future of the American shipbuilding industry. Largely, it is devoted to statistics of shipping today, specifically outlining the prospects in the various maritime countries. It finally urges the necessity of the United States having a gross tonnage of 7,500,000 to take care of its prospective foreign trade, but the report gives no indication of what the policy of the Government will be with regard to future shipbuilding and ship ownership. A suggested policy will probably be made public by Mr. Hurley in a speech in New York Mar. 27.

Mr. Hurley says that there is a false impression in this country regarding the importance on a prospective merchant marine of the high wages required to be paid to seamen under United States laws. He says that not only do the leading shipping nations in the world pay just as high wages, but that wages are so small a proportion of the cost of operating a ship as to make them of small effect on total costs.

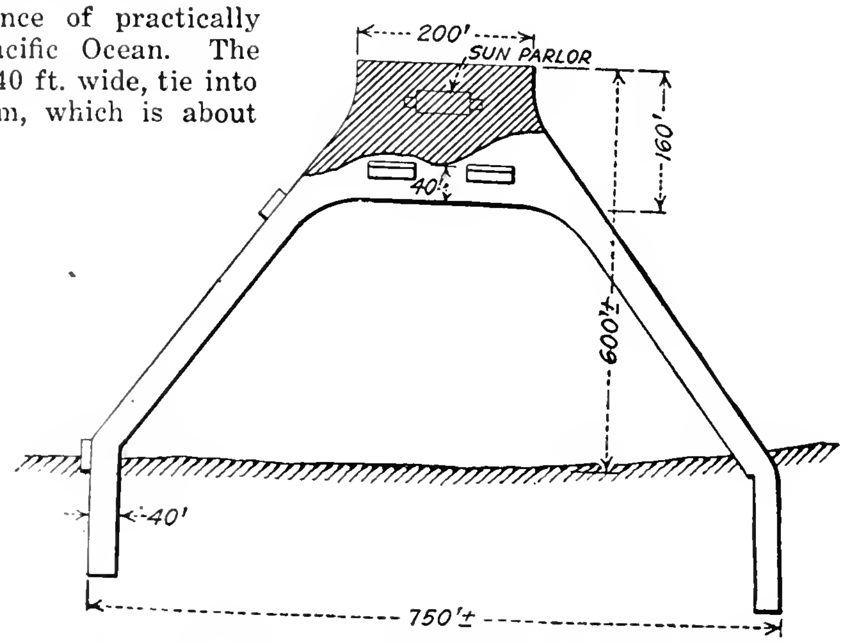
The statistics on present ship tonnage show that the total oceangoing tonnage of the world in 1914 was 41,295,000 gross tons. Today similar figures are 37,100,000 gross tons, the net loss of over 4,000,000 being due to the destruction of much more than that plus the increase due to production of ships during the four years of war. The falling off of normal increase by new construction which would have continued had the pre-war rate stood would amount to about 12,000,000 gross tons, so that there is today a shortage of 16,000,000 gross tons. In August, 1914, the United States seagoing merchant marine, 500 gross tons and over, included 624 steamers of 1,758,465 gross tons and 837 sailing vessels and schooner barges of 947,852 gross tons, making the grand total of 1490 seagoing merchant vessels of 2,706,317 gross tons. In November, 1918, the steam merchant marine had increased to 1366 vessels of 4,685,253 gross tons and the sailing vessels and schooner barges had decreased to 747 vessels of 829,917 gross tons, mak-

ing the grand total 2113 seagoing vessels of 5,515,180 gross tons. This does not include the seized enemy vessels, which at the end of the war averaged 88 vessels of 562,005 gross tons, of which number 81 are of 546,210 gross ton, steamers, and seven of 15,795 gross tons were sailing vessels. The total construction in the United States added to the merchant marine during the war amounted to 875 vessels of 2,941,845 gross tons.

Ocean Undermines Concrete Pier at Redondo Beach, California

The outer portion of the concrete pleasure pier at Redondo Beach, California, collapsed during a heavy windstorm on the night of Mar. 6. This pier, which was fully described in *Engineering News* of Sept. 14, 1916, p. 518, is in the form of a triangle extending out a distance of practically 600 ft. into the Pacific Ocean. The two legs, each about 40 ft. wide, tie into the outshore platform, which is about 160 x 200 ft. in plan. The structure was of reinforced-concrete girder and slab construction supported on reinforced-concrete piles which were jetted into place. It carried a sun parlor, an observation tower and other appurtenances.

DAMAGED OUTER END OF REDONDO BEACH PIER SHOWING COLLAPSED FLOOR WHERE PILING WAS WASHED OUT



PLAN SHOWS PART OF PIER WHICH FAILED

As shown on the diagram herewith, a large part of the outer section was washed away. At the present time, the failure of the pier is attributed to an unusual undertow washing the sand away from the piling. The end of the pier terminates at the head of a submarine cañon whose side and bottom slopes are very deep compared with the gradient of the surrounding ocean floor. There was a terrific undertow following the storm, and it is thought that possibly the cañon banks were affected by this action. The reinforced-concrete piles varied from 20 to 85 ft. in length; it is not known just how deep was their penetration, although it is thought that at the outer edge it was about 25 feet.

The City of Redondo is planning to repair the pier and has employed W. K. Barnard of Los Angeles to investigate the extent and cause of the damage.

Railroads Now Can Coöperate in Local Improvements

Although issued Dec. 30, 1918, the Railroad Administration order permitting the railroads to coöperate in local improvements does not seem to have had wide circulation, because a number of municipal authorities have recently written to Washington saying that local municipal projects were being held up because the railroads refused to assume their proportion of the cost. Circular No. 44, issued by the United States Railroad Administration July 29, 1918, permitted the railroads to refrain from coöperating in local improvements other than those of imperative necessity. This order has now been set aside, and such joint action on improvements should now be taken up by local municipal authorities in coöperation with the railroads, just as they were before the war.

No Freight Rate Reduction on Building Material

Freight rates on building material will not be reduced, according to an official statement of the Railroad Administration which reads as follows:

"Various inquiries have been received as to whether the Railroad Administration contemplates a reduction in freight rates on materials used in construction of buildings, and therefore it becomes important to make it clear that no such reductions are in contemplation. The Railroad Administration is, however, giving consideration to the question of making reduced rates on crushed rock, stone, sand, and gravel for road construction when consigned to and the freight thereon is paid by a Federal, State, county, parish, or township government. Before the matter can or will be definitely determined it is intended to ascertain what, if any, reduction necessary to establish a stable price will be made in the price by those producing and supplying the materials."

Highway Bond Issue for $30,000,000 Vetoed in Arizona

A bill clearing the way for a $30,000,000 bond issue for constructing roads in Arizona has been vetoed by the Governor. The bill provided for a highway commission of five members, and the objection of the Governor to this form of supervision is given as the reason for the veto.

Oregon Passes Highway Bond Issue for Ten Million Dollars

By utilizing an emergency provision, the legislature of Oregon, with the approval of the governor, has eliminated the necessity of putting to the vote of the people the measure providing for a bond issue of $10,000,000 for highway purposes.

This amount of money, which is thus made immediately available, when combined with the Federal aid to be received in the next two years and a portion of the $5,000,000 bond issue now being planned by the reconstruction committee of the legislature, will provide a large amount of money for highway work in the state during the coming year.

Exhibit of Army Personnel Work To Be Shown

Methods developed by the Committee on Classification of Personnel in the United States Army will be shown at an exhibit at the Engineering Societies Bldg., 29 West 39th St., New York City, Apr. 1-12, under the auspices of the National Association of Corporation Schools, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers.

The exhibit consists of a collection of wall charts, forms, photographs and models showing how the Army finds out what men can do best and how it uses that information; how soldiers are trade tested, and how officers are rated and fitted into place; how the work is checked and supervised, and its results in the war. The exhibit was shown for several weeks at Washington, where it excited so much interest that, in response to many requests, the Adjutant General consented to its display in other cities. Two commissioned officers accompany the exhibit to explain its features.

Los Angeles Wants To Sell Cement Mill

The first and only municipal portland cement mill is now being offered for sale, as has been noted in several of the advertising pages of this journal. This is the Monolith mill built in 1908 by the City of Los Angeles, Calif., for the manufacture of cement to be used in the mammoth Los Angeles aqueduct. The plant is situated 117 miles north of Los Angeles, and includes contiguous and almost inexhaustible deposits of clay and limestone. The city has been in doubt for some time as to its disposition, but finally has decided that it cannot enter into commercial competition in the production of cement and that the mill is much too large for the needs of its own construction.

The mill is notable because it was utilized in the production of a tufa cement, using a volcanic deposit in close proximity to the mill. This blended cement required additions to the mill, so that today it has a capacity for a blended cement of about 1500 barrels.

Urges United Port of New York

In a paper read before the Society of Terminal Engineers Mar. 18, A. T. Skougor, engineer of the Chile Exploration Co. of New York, proposed a plan for a united port of New York and New Jersey which contained some features not hitherto included in similar projects. Mr. Skougor's preliminary contention is that a new state should be formed out of the districts immediately contributing to the port of New York, with the idea of furnishing one government and unified aims for the development of the port. He asserts that joint action will never amount to much. He urges that after such a state has been formed some engineer of national reputation be selected to plan, design and construct the port, having a free hand to select his staff, and that the port once having been developed, a Governor be appointed who will have full control of its administration.

In the design of this new port all efforts should be concentrated to divert from Manhattan Island all of the freight not essential to Manhattan, and that Manhattan shore should be used mainly as a passenger steamship port.

Engineers Will Discuss Federal Public Works Department

The Engineering Council through its National Service Committee has sent out invitations to 152 representative engineering societies of the United States, requesting the selection of delegates to attend a national conference on the establishment of a Federal department of public works. The conference is to be held in Chicago, Apr. 23-25.

With the invitation there has been sent to each society a general plan of organization for the conference and a statement of some of the principal questions which the conference will have to consider. It is requested that the societies take up these questions and, if they so desire, vote upon them, prior to the conference.

The calling of this conference follows close on the action of the Engineering Council on Feb. 20, 1919, advocating the establishment by Congress of a department of public works and urging engineers in all branches of the profession to use their influence to arouse public opinion so that the importance to the national welfare of such a department may be understood.

State Utilities Commission the Proper Agent

The State Supreme Court of Kansas has ruled that the Public Utilities Commission of the state is the proper means of compelling a utility company to give sufficient and efficient service. The decision was rendered in a suit brought by the City of Parsons against the Parsons Water-Supply & Power Co. to obtain the appointment of a receiver on the plea that the company had violated its franchise by not furnishing water in sufficient quantity and with sufficient pressure. The Supreme Court denied the application for a receiver and held that the courts will not decree specific performance so long as the proper remedy is offered through appeal to the Public Utilities Commission.

News Item on Appropriation for Federal Aid Corrected

Through an error, a news item announcing the passage of the Federal-aid highway appropriation for $200,000,000, which was published in *Engineering News-Record* Feb. 27, p. 446, was reprinted in the issue of Mar. 20, p. 592.

Civil Service Examinations

For United States Civil Service examinations listed below, apply to United States Civil Service Commission, Washington, D. C., or to any local office of the commission, for form 1312.

United States. — Senior highway bridge engineers, Apr. 1, Bureau of Public Roads, Department of Agriculture, Washington, D. C. Grade 1 (examination percentage above 70) $2400 to $2700 per year; Grade 2 (percentage above 80) $2800 to $3000 per year; Grade 3 (percentage above 90) $3100 to $3500 per year. File application before Apr. 1.

United States.—Engineer-draftsman, Apr. 22, $1500 to $1800 per year. File application before Apr. 22.

United States.—Transitman, $100 to $125 per month, and surveyor, $125 to $200 per month, Mar. 26-27 and Apr. 23-24. File applications in time to arrange for examination at place selected by applicant.

Engineering Societies

Calendar

Annual Meetings

NATIONAL FIRE PROTECTION ASSOCIATION; 87 Milk St., Boston, Mass.; May 6-8, Ottawa, Can.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

AMERICAN SOCIETY OF CIVIL ENGINEERS; 29 W. 39th St., New York; June 17-20, St. Paul-Minneapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS; University of Pennsylvania, Philadelphia; June 24-27, Atlantic City.

The Albany Society of Civil Engineers will hold a meeting Mar. 27 at which R. E. Brooks, district manager for the Koehring Machine Co., will speak on "Modern Methods of Handling Material," with special reference to economy. The lecture will be illustrated by motion pictures.

The Engineers' Society of Milwaukee held its regular monthly meeting Mar. 19 under the auspices of the Milwaukee Section of the American Society of Refrigerating Engineers. J. R. Watson, of Chicago, spoke on "The Use of Synchronous Motors with Ammonia Compressors." Duncan Watson, M. I. E. E., alderman of London, England, and chairman of the Joint Conference on Electrical Undertakings of Greater London, addressed the meeting.

The Engineers' Club of St. Louis held a joint meeting Mar. 19 under the auspices of the St. Louis Association of Members of the American Society of Civil Engineers, at which Lieut. Col. F. G. Jonah, Engineers, U. S. A., previously chief engineer of the Department of Light Railways, American Expeditionary Forces, and now chief engineer of the St. Louis-San Francisco and the Missouri, Kansas & Texas Rys., spoke on the "Construction of Light Railways in France."

The Utah Society of Engineers held its monthly meeting Mar. 19. The following papers were presented: "Recent Improvements in Steam Prime Movers," by Prof. E. H. Beckstrand; "Modern Internal Combustion Engines," by Prof. A. L. Taylor; and "Water-Wheel Development," by L. M. Pharis, hydraulic engineer, Utah Power and Light Co. Calvin W. Rice, secretary of the American Society of Mechanical Engineers, will address the society Apr. 7.

The Engineers' Club of Philadelphia will hold an informal meeting Apr. 9 at which Roland L. Cummins, of the Packard Motor Car Co., will give a demonstration of the Liberty motor. The method of manufacturing Liberty motors will be illustrated by motion pictures. The regular monthly meeting will be held Apr. 15 and will be addressed by S. M. Swaab on "Main Interchange Station Under the City Hall, Philadelphia Subway System"; the address will deal with unique construction methods made necessary by conditions imposing exceptional difficulties. A special meeting will be held Apr. 23 at which Arthur J. Baldwin, vice-president of the McGraw-Hill Co., Inc., will present an illustrated paper entitled "The Devastated Area and Its Reconstruction." Mr. Baldwin was a member of a party of technical and business paper editors and publishers who were invited by the British Ministry of Information, as its guests, to visit Europe.

The American Water-Works Association's nomination committee has made the following nominations for office, which are now being voted on by mail: President, Carleton E. Davis, chief of the Bureau of Water, Philadelphia; vice-president, Capt. M. L. Worrell, Q. M. C., U. S. A., in charge of utilities at Camp Hancock, Georgia; treasurer, James M. Caird. W. H. Randall, superintendent of maintenance of the Water Department of Toronto, Ont., and F. C. Jordan, secretary of the Water Co. of Indianapolis, Ind., are the nominees for trustees.

The Vermont Society of Engineers was addressed by Maj. Gen. Clarence R. Edwards, commander of the Northeastern Department, U. S. A., at the annual meeting held at Burlington Mar. 12. John K. Hooper, meteorologist of the United States Weather Bureau station at Burlington, read a paper on "Rainfall in Vermont in 1918" and Charles H. Pierce, district engineer, United States Geological Survey, Boston, read an illustrated paper on "Stream Gaging in Vermont." Officers were elected for the ensuing year as follows: President, C. F. Purinton, Burlington; vice-president, F. D. Denison, St. Albans; secretary, G. A. Read, Montpelier.

The Indiana Society of Sanitary Engineers elected the following officers at the annual meeting in Terre Haute, Mar. 12: President, William J. Woolley; vice-president, E. Kanney; secretary-treasurer, Claude McElwaine.

The Ann Arbor Engineers' Club elected the following officers at the regular meeting Mar. 13: President, George H. Sandenburgh; vice-president, Robert Norris; secretary-treasurer, F. Leslie Feiner.

The Rochester Engineering Society was addressed Mar. 14 by Le Grand Brown, who delivered an illustrated lecture on "California." Miss Kate Gleason was the speaker at the luncheon Mar. 17. Leon R. Brown, New York State Railways, addressed the meeting Mar. 21 on "Taking Soundings in the Niagara River." The meeting Mar. 28 will be addressed by H. A. Winne, of the General Electric Co., on "Electric Furnaces."

Personal Notes

A. A. MATTHEWS, formerly chief engineer of the St. Louis Southwestern R.R. of Texas, has been appointed chief engineer of the group of railroads in the Southwestern region comprising the St. Louis Southwestern R.R., the St. Louis Southwestern R.R. of Texas, the Eastern Texas R.R., the Dallas Terminal Railroad and Union Depot, the Southern Illinois and Missouri Bridge and Louisiana and Arkansas Railroad.

GEORGE C. D. LENTH, for the past eight months general superintendent for the M. J. Corboy Co., on the construction of a sewer system and water-supply at Camp Henry Knox, Kentucky, has returned to his former position as assistant chief engineer of the Board of Local Improvements, Chicago.

LIEUT. F. E. SCHNEPFE, Construction Division, U. S. A., has received his discharge from the service and is now associated with the Lime Association as district engineer of the Southeastern District, with headquarters in Washington, D. C.

A. M. KRAMER, field engineer, Portland Cement Association, for western New York, has resigned to become affiliated with the Universal Portland Cement Co., with office in Pittsburgh.

LIEUT ADOLF HINRICHS, Engineers, U. S. A., has received his discharge from the service and has become secretary of the Woodbury Service, Inc., appraisal and production engineers, New York City.

FREDERICK WILLIAMS, junior engineer, Wilmington, N. C., has been transferred to the United States Engineer Office, Third District, New York City.

COL. SIDNEY B. WILLIAMSON, 55th Engineers, U. S. A., returned to this country Mar. 20 and has received his discharge from the service. He will resume his work as consulting construction engineer for Guggenheim Brothers.

CAPT. JOHN K. FLICK, Engineers, U. S. A., assistant to the Constructing Quartermaster, Curtis Bay Ordnance Depot, has been discharged and has become associated with Arthur Farmer, under the firm name of Farmer & Flick, engineers and contractors, 15 East Fayette St., Baltimore.

EDWIN B. BURCHARD, Office of United States Geological Survey, in Albany, has been transferred to the station at Ames, Iowa, where he will work in coöperation with the Iowa State Highway Department and the State Agricultural College.

P. H. WITHINGTON, A. B. ROBERTS and G. OTIS WRIGHT have become associated under the firm name of the Withington-Roberts-Wright Co., engineers, with main offices in the Swetland Building, Cleveland. Branch offices are located in Boston, New York, Baltimore and Chicago.

WILLIAM H. CUSHMAN has left the service of the Hydraulic Construction Co., Watertown, N. Y., and has opened offices in the Flower Building, as a consulting hydraulic engineer.

LIEUT. COL. WILLIAM C. SHERMAN, Corps of Engineers, U. S. A., who is an aviator and has been connected with the air service for some time, has been detailed as chief of Air Service Training, which will include heavier-than-air training at the ground schools and flying fields under Brig. Gen. William Mitchell.

LIEUT. W. G. SLOAN, 49th Engineers, U. S. A., stationed at general headquarters in France, has received his discharge from the service and has returned to his position as representative of the Irrigation Division, Bureau of Public Roads, United States Department of Agriculture, for Idaho and Eastern Oregon, with headquarters at Boise.

J. WENDELL MOULTON, Office of United States Geological Survey in Boston, has been transferred to the office in Albany, N. Y., replacing Edwin B. Burchard, transferred to Ames, Iowa, as noted elsewhere.

WARREN G. SWENSON, consulting engineer, of Pocatello, Idaho, has been appointed State Engineer of Idaho. After his graduation in civil engineering from the Utah Agricultural College in 1903, he entered the

service of the Utah Experiment Station, in charge of field operations and irrigation experiments. Later he became connected with the United States Reclamation Survey and afterwards served as engineer of the Telluride Power Co. In 1907 he became associated with the Beaver River Power Co. in charge of hydraulic engineering and construction, afterwards engaging in private practice, during which he has specialized in water-power and irrigation work.

CAPT. C. E. HICKOK, Engineers, U. S. A., who received his discharge from the service Jan. 1 and is now city engineer of Alameda, Calif., has been appointed major in the Engineers' Reserve Corps.

T. N. JACOB, civil engineer and specialist in land drainage and flood-prevention work, East St. Louis, Ill., has taken offices in the Boatmen's Bank Building, St. Louis, Mo.

GEORGE MOAGE, Wauseon, Ohio, has been appointed city engineer of Grand Haven, Mich.

W. S. MOORE, formerly city engineer of Grand Rapids, Mich., has become associated with the Simplex Mfg. Co., of Bethlehem, Penn.

MAJ. K. C. GRANT, Construction Division, U. S. A., has received his discharge and has returned to Dayton, Ohio, where he has become a member of the firm of Frank Hill Smith, Inc., engineers. Before entering the Army, in April, 1917, as a captain of engineers, he was division engineer for the Miami Conservancy District, with headquarters in Dayton.

MAJ. F. I. WHEELER, Corps of Engineers, U. S. A., has been discharged from military service and has returned to Cleveland to resume his duties as assistant engineer with Col. D. W. Lockwood, Corps of Engineers, in charge of the river and harbor district, embracing the lake shore of Ohio from Toledo to Conneaut. During the past year and a half Major Wheeler has been constructing quartermaster at Camp Johnston, Florida, and Camp Shelby, Mississippi, previous to which he was in charge of the construction of roads at Camp Sheridan, Alabama.

J. K. WILSON, of Grand Rapids, Mich., has become field engineer, Universal Portland Cement Co., with headquarters in Chicago.

CAPT. A. C. NELL, Construction Division, U. S. A., in charge of the purchase of power and mechanical equipment in the Construction Division, has received his discharge from the service and has been appointed Chicago district manager for the Lea-Courtenay Co. and the Schutte & Koerting Co. Captain Nell was formerly connected with the Allis-Chalmers Manufacturing Company.

IRA W. MCCONNELL, formerly works manager and assistant general manager, American International Shipbuilding Corporation at the Hog Island shipyard, has become vice-president of the Dwight P. Robinson & Co., Inc., constructing and consulting engineers, of New York City. After his graduation from Cornell University, in civil engineering, in 1897 he served two years as instructor and was afterward professor of civil engineering at the Missouri School of Mines. He later became connected with the United States Reclamation Service in charge of work on several projects, including the Uncompahgre project and the Gunnison tunnel. In 1909 he became chief irrigation engineer for J. G. White & Co., Inc., New York City, and was later appointed vice-president and general manager of the Idaho Irrigation Co. at Richfield, Idaho. In 1912 he became associated with Stone & Webster as a consultant.

WALTER RENTON INGALLS, for 14 years editor of the *Engineering and Mining Journal*, McGraw-Hill Co., Inc., has retired to reënter professional practice as a consulting engineer, with offices in New York City. However, he will not sever his connection with the *Journal*, but will continue to act as consulting editor and will remain in full charge of recording the weekly metal markets, making the quotations as heretofore. H. C. PARMELEE becomes acting editor without relinquishing the editorship of *Chemical and Metallurgical Engineering*, McGraw-Hill Co., Inc.

JAMES W. ROUTH, engineer, Rochester Bureau of Municipal Research, has been appointed director of the bureau, succeeding Le Roy E. Snyder, resigned. Mr. Routh has been associated with the bureau since its establishment four years ago, having previously been the principal worker in the preliminary survey of the local government. He had also been associated with the New York Bureau of Municipal Research. He is a graduate in engineering from the University of Minnesota and Cornell University.

D. T. BLACK, for eight years city engineer of Welland, Ont., has been appointed city engineer of Niagara Falls, Ont., succeeding Frederick Anderson, killed in action in France.

D. H. FLEMING, assistant city engineer of St. Catharines, Ont., has been appointed town engineer of Owen Sound, Ont.

W. L. STEVENSON, who from April, 1918, to the signing of the armistice, was sanitary engineer and assistant director of the Department of Health and Sanitation of the United States Shipping Board, and since then has been engaged in special work for the Emergency Fleet Corporation, has been appointed assistant chief engineer of the Pennsylvania Department of Health, with office at Harrisburg. He was previously assistant engineer in charge of investigations, reports, design and construction of intercepting sewers and sewage-treatment works of Philadelphia.

J. E. FERGUSON has opened offices in the Spitzer Building, Toledo, as a consulting and contracting engineer. Mr. Ferguson was formerly general manager of operation of the American Steel Co. of Cuba, previous to which he was general superintendent of the Toledo Bridge & Crane Co. of Toledo, Ohio.

CAPT. C. F. WAGNER, Engineers, U. S. A., has received his discharge from the service and has become chief engineer for the J. B. McCrary Co., Atlanta. Captain Wagner was supervising constructing quartermaster of coast defenses and later was officer in charge of construction, Camp Eustis, Virginia.

G. H. BISHOP, of Atlanta, has resigned as assistant sanitary engineer of the United States Public Health Service.

MAJ. RICHARD MESSER, Construction Division, Maintenance and Repair Branch, U. S. A., has received his discharge from the service and has returned to Virginia as chief engineer for the State Board of Health. He had charge of the section having general supervision over the operation of water-supplies, sewerage systems and treatment plants at cantonments, camps and other Army posts.

OBITUARY

E. K. LOVELACE, Cadillac, Mich., district engineer on the staff of the State Highway Engineer, died at Ann Arbor Mar. 6. He was at Ann Arbor in attendance at the university short course in highway engineering.

JESSE T. VOGDES, chief engineer and superintendent of Fairmount Park, Philadelphia, for 21 years, died in that city Mar. 18, at the age of 61. He entered engineering work in 1880 and became assistant engineer to General Thayer, who was chief engineer of Fairmount Park. The improvement of 34th St. in front of the Zoölogical Gardens, where the land was formerly a swamp, was begun and finished under his direction. He also superintended the construction of the East River drive from Lincoln Monument to the Wissahickon.

HARVEY M. GEER, consulting engineer, Ballston Spa, New York, died in Troy March 18. He was graduated from Rensselaer Polytechnic Institute in 1872, after which he entered engineering work and later became engaged in contracting. In 1876 he became assistant engineer on surveys for the water commissioner of Troy, and continued in municipal work. He had charge of the construction of water-supply systems in Johnstown, N. Y., Amsterdam, N. Y., Macon, Ga., and Westboro, Mass.

Price of Steel Lowered

Steel both in mill and warehouse has been reduced in price as a result of a joint meeting of representatives of the Iron and Steel Institute and the Industrial Board of the Department of Commerce, Mar. 20. The price of pig iron was lowered $4.25 per ton; steel, $7, at mill. The price of iron ore, $5.50 a ton, will remain the same. The object of the decrease is partially to restore business and industry to a peace basis.

The effect of this drop is already reflected by dealers. Beams and channels of 3 to 15 in., angles of 3 to 6 in., and 3-in. tees have declined from $4.07 in New York and Chicago to $3.47; plates, from $4.27 to $3.67.

At the conclusion of the conference, when the new schedule had been made public, Judge Gary said, "It is expected that prices for 1919 will not be any lower." This means that prospective buyers may go ahead with their projects, practically secure in the knowledge that iron and steel prices have been definitely fixed for this season.

Government Will Sell Accumulated Stock of Copper

Arrangements have been made by the War Department to sell a stock of approximately 100,000,000 lb. of copper, which it controls, at market prices, during the next 15 months. This is the result of an agreement with copper producers. The United Metal Selling Company, organized for the purpose by the producers, will handle the transaction.

For the first 10 months 5,000,000 lb. per month will be sold, and thereafter 10,000,000 lb. per month, until the stock is disposed of. The basis of the agreement is a stipulation that the producers shall absorb the stock at a rate equal to 10% of their sales. A small amount to cover the expense of sales is paid to the producers, and if market conditions improve the sales per month will be increased.

Plans for Utilizing Waste Explosives

When the munitions and shell-loading plants are finally closed, the Government will have on its hands hundreds of thousands of pounds of explosives consisting of scrapped TNT, amatol, ammonium nitrate, etc. Timothy D. Gleeson of New York, president of the Association of Practical Inventors of America, and formerly connected with the United States Ordnance Department as supervisor of plant safety and supervisor of amatol, has suggested several plans by which these explosives could be disposed of, and make unnecessary the plan some are advocating—that they be carried out to sea and dumped into the ocean. Instead of this wasteful procedure, he suggests that they should be utilized so that contractors, engineers, and farmers would obtain immediate benefit.

For example, farm acreage in meadows might be measured by blasting out stumps and undergrowth; new roads might be made in rocky regions; streams with soft mud bottoms might be deepened by scientifically exploding moderate charges at proper points. Along railroads, where slides of loose rock or earth occur, these menaces could be cheaply removed by these explosives, obtained at little or no cost. In many rivers and harbors are projecting reefs and movable sandbars that endanger navigation. These could be blasted out and removed.

Argentine-American Chamber of Commerce Formed

Formation of an Argentine-American Chamber of Commerce in New York City, under the auspices of the Chamber of Commerce of Buenos Aires, has been announced by Enrique Gil, secretary of the organization. Its purpose is to foster trade relations between the two countries, to encourage investment of American money in Argentina, and to serve as a clearing house for all business. The membership will include citizens of both countries.

Business Notes

Amplex, Inc., New York and Tokio, announce that they will remove their New York office Apr. 1, to the 17th floor of 6-8 West 32d St. This firm acts as representative of American manufacturers in Japan and China.

W. J. Austin, general manager of the Austin Co., industrial engineers and builders, Cleveland, Ohio, has just returned after spending three months in France, Belgium and England. While in Europe, Mr. Austin and his party were guests of the British Government for a considerable time, visiting many sections and interviewing leaders of industry in foreign countries, and he believes that friendly conditions which have resulted on account of the war have already given American manufacturers a good start toward winning new markets in Europe. In the party were J. K. Gannett, export sales manager of the Austin Co., and Alvan T. Fuller, member of the House of Representatives from Massachusetts.

The Chicago Pneumatic Tool Co. announces the following changes in office locations and personnel: The Detroit office has been removed from 236 Hancock Ave. to 502 Farwell Bldg.; the Boston office has removed to 182 High St., and is in charge of F. S. Eggleston; offices have been opened with warehouses at Tulsa, Okla., and El Dorado, Kan.; J. I. Edwards has been appointed manager of rock drill sales, succeeding E. Eklund, recently appointed foreign representative; Fred H. Waldron, formerly stationed at Minneapolis, has been appointed manager of pneumatic tool sales, with headquarters in Chicago, succeeding J. G. Osgood, resigned; Nelson B. Gatch has been appointed manager of sales at the Minneapolis office, 301 Metropolitan Bank Bldg., and J. K. Haigh has been appointed assistant district manager of sales at 175 First St., San Francisco.

An organization, known as the Eastern Paving-Brick Manufacturers' Association, to advance the interests of paving-brick manufacturers of New York, Pennsylvania, Ohio and West Virginia, was perfected as a result of a meeting held recently at Harrisburg, Penn.

The Associated Metal Lath Manufacturers, who formerly had their offices in the Swetland Bldg., Cleveland, Ohio, have decided to move them to Chicago, Ill., the former home of Wharton Clay, who has been elected commissioner of the organization.

Trade Publications

"Tarvia Road Book" is the title of a handbook just issued by the Barrett Co. for the use of engineers who are applying tarvia to their roads. It contains 70 pages, is 3½ x 6 in. in size, is neatly bound in leather and consists of tables useful to road engineers, together with specifications for applying tarvia. Among the tables are: The quantity of tarvia per mile; distance covered by various tank capacities; weight per cubic yard of various substances; spacing for covering material in half-ton piles; costs per mile at price per square yard, and many others. The book will be sent, on request, from any of the Barrett Co.'s offices.

"Pointers to Profits" is the title of a 7 x 10-in. catalog of 64 pp. just issued by the Acme Motor Truck Co. of Cadillac, Mich. Descriptions and illustrations of the operation of motor trucks, with specifications for sizes from one to five-ton capacities, are given.

Collapsible steel forms for concrete culverts from 13 to 15 in. to 36 x 46 in. in section are described in detail in a 24-p. pamphlet, 9 x 6 in., issued by the Illinois Culvert Form Co., Marseilles, Ill.

The Union Iron Products Co., of East Chicago, Ind., has issued a 3½ x 8½ in., 11-p. catalog illustrating "Wearproof" traffic direction signs, warning signs, metal highway markers and street nameplates. These signs are shown in colors and the accompanying descriptions give prices.

Cutting and breaking asphalt pavement and loosening frozen coal are two emergency uses for tie tampers described in the new Ingersoll-Rand tamping outfit catalog, which covers the company's outfits for track work.

Volume 82   NEW YORK, THURSDAY, APRIL 3, 1919   Number 14

Real Military Engineers Were Needed at the Front

MOST of the engineers in the great war found service somewhere behind the lines. The proportion so engaged, which has been variously estimated up to as high as 95%, reached all the way from the immediate Service of Supply in France back to the ports in this country and to the camps and factories which contributed the men and material for the fighting front. So large was this proportion and so important was the work they did, that the more spectacular services of the fighting engineers have been lost sight of in the current engineering stories of the war. But no American engineer should forget that throughout the months that we were in action, up under fire of the German guns there were always thousands of brave, indomitable, resourceful men, with the castle of their corps on their collars, pushing forward with and at times ahead of the infantry spearhead which broke the German line. This was military engineering pure and simple. All else that the engineer did was civilian engineering necessary to the conduct of a war. It required little of military intelligence, little of military experience. The divisional engineers, a glimpse of whose work Captain De Leuw gives in his article on another page, were the real fighting engineers. Their work, or at least the direction of their work, requires military-engineering training. The men who carry it out must be, above all, soldiers, and the major part of their experience certainly should be that of a soldier.

Morale as a Disregarded Asset

A FURTHER blow has been given to the strength of the engineering organization engaged in subway construction in New York City. The city authorities delayed until Mar. 28, three days before the end of the quarter, the money appropriation necessary for continuing the engineering staff in service after Apr. 1. Last December the same proceeding was carried considerably farther; the appropriation was delayed until a month overdue, leaving the subway construction work substantially without an engineering organization for a full month. When the organization was reassembled, the damage done by the delay became quickly apparent. Some men did not return to the service. Others, perhaps most of the remainder, had had their allegiance to the commission's work profoundly shaken, and as a sequel a distinct loss of the spirit of loyal service and coöperation necessary in every great enterprise became apparent. No member of the organization knew whether his activities would continue after the last day of March. Even more after last week's performance, the commission's engineers have no certainty whatever as to the continuity of the work. The city authorities have seriously injured the morale of the organization.

Detroit Water-Filtration Experiments Fully Justified

ANOTHER experimental water-treatment plant has been justified by the light it has thrown upon the design of proposed works to treat the water-supply of a city, as shown by the brief article on page 662. A full year's tests show that the Detroit supply can be treated at a much higher unit rate than is common to mechanical filtration in the Central West. The tests also indicate that alum will be preferable to lime and sulphate of iron as a coagulant for this water. It is to be hoped that the plant will soon be put under construction. Complete treatment of the water would presumably lower the somewhat high typhoid and general death rates, besides effecting a marked improvement in the appearance of the water. The educational work done in connection with the experimental plant is commendable.

To Direct Federal-Aid Road Work

ALMOST on the day that last week's issue of *Engineering News-Record* went to press announcement was made that Thomas H. MacDonald, chief engineer of the Iowa State Highway Commission, had been appointed engineer in charge of the work under the Federal-aid road act. It will be remembered that last week's issue urged that the new director for the Bureau of Public Roads be appointed as quickly as possible. Mr. MacDonald's appointment is not as director, but as engineer in charge of the Federal-aid road work, this apparently being due to the failure of Congress to vote an adequate salary for the man who is to supervise a $200,000,000 expenditure of Federal money. Mr. MacDonald will eventually succeed to the post of director, but not, we hope, until the Congress of the United States votes a fitting salary. Mr. MacDonald goes to the job with excellent qualifications, both as to personality and experience. As chief engineer of the Iowa State Highway Commission, he has handled a good-roads project almost parallel to that, though on a smaller scale, of the Federal-aid act. In Iowa the state supervises all the county work, though the work is paid for by the counties. Obviously, the directors of such work must proceed with extraordinary tact and with full appreciation of the local problems. The points of view necessary for success in Iowa are exactly those necessary in the larger post to which Mr. MacDonald is now going. The whole highway field has confidence in him and will gladly pledge him hearty and unqualified support.

A Workable Shipping Plan

IN THE plan outlined by Chairman Edward N. Hurley of the Shipping Board for a permanent ship-operating policy and system for the United States, the first workable and well considered proposal to solve the sea transportation problem is laid before the nation. Shipping men, who might well have worked toward a solution of the problem before this, appear to have maintained an attitude which at the best was passive. Their interests, of course, are by no means simple, nor are they identical with those which Chairman Hurley represents, for the habit of foreign control has not yet passed from our shipping industry. Because little has been done toward solving the problem up to now, we must welcome a plan based on Mr. Hurley's steadfastly aggressive championship of a permanent American sea commerce. This stand, and the shrewdness he has displayed in most phases of the Shipping Board's negotiations, give great weight to his plan.

It is a workable plan, we have said. The major difficulties of the sea transportation problem are duly taken care of. Skillfully turning the flank of the seaman labor problem, the plan removes one of the two essential causes for apprehension concerning our merchant-marine future. It deals with the other difficulty, that of excessive capital account, by providing for selling vessels at the current market price, just as has been done in England. The plan suggested is practicable and until something better is presented it is bound to form our working hypothesis of ship administration.

What is important for every citizen, whether he be engineer or not, to remark concerning this plan, is that our great Government merchant fleet will largely be completed before the plan can be adopted, organized and started in operation. Our fleet of ten million or more tons will be at work, soliciting, receiving and carrying freight, before the new machinery can take hold of the service. This will mean that at all events the Government must go into ship operation temporarily, and that its operating organization must be developed and enlarged to care for the increasing duties. With such enlargement the Shipping Board will be able to carry on operations temporarily without any need for hurrying the final shaping of the plan, and at the same time its accumulating experiences may be put to use in perfecting the details of the plan. It is quite important that this condition be clearly seen, as otherwise the country may be led into hasty action with regard to the release and sale of its ships, which may start the disorganization of our merchant marine before even it is created. The great present question is to get the ships going, not how they are to be kept going.

Three phases of the shipping problem and Mr. Hurley's plan are of primary importance, in so far as they have relation to engineering work in addition to ship operation. These phases are the close parallelism between the railroad problem and the shipping problem; the question of foreign terminals; and the question of future shipbuilding.

Precisely the same mixture of public service and private interests is found in our shipping as in our railroad problem—provided we take the same public-interest stand as Mr. Hurley, who frankly bases his argument and his plan on the overshadowing importance of developing the shipping industry for the greatest good of the country. There are, moreover, precisely identical difficulties in the two cases. Both involve capital-account questions that seem to make it inevitable for the Government to take a loss chargeable to war cost. Both require the same adjustment between hitherto customary rates and a higher wage level. Both present the triple question of Government operation or Government control or uncontrolled private operation. Despite many surface dissimilarities, the two subjects, railroad and shipping, become more closely similar the more fully the case is studied.

That Mr. Hurley has provided in his plan for intimate coöperation of Government and private functions is of extreme interest in its bearing on the best solution of the railroad problem. He avoids Government ownership, but instead counts on turning every piece of property over to private owners just as quickly as possible and without any restrictions. He arranges for Government financing, and virtually makes Government credit available by using the difference between Government and commercial interest rates to produce an emergency fund which shall protect the whole system in its operation and equalize individual losses. He arranges for control with respect to essential public interests, so that, for example, ship routes shall be established as our commerce needs them; but beyond this he leaves the business wholly free from regulation. Finally, he arranges for covering certain losses by the emergency fund to be drawn from excess interest payments on the purchase mortgages and from excess of private over Government insurance rates.

In emphatic advocacy of our present seamen's protective laws and in a refutation of the oft-made claim that they put American shipping at a tremendous disadvantage, Mr. Hurley, in his report on his European trip, rendered just before the publication of his plan, has exhibited a resolute determination to take account of the irresistible world drift toward stabilized labor conditions. He shows that the storm which has raged about this subject for quite a time past has not shaken him. At the same time, however, it is evident that his plan, though it makes no express provision for any unbalanced labor cost which might render American operators unable to compete, does, in fact, allow for this difficulty. Through the power of the administrative board and its emergency fund of many millions of dollars, the object can be attained. There is no such word as subsidy in the plan.

It is instructive in relation to the railroad problem to observe how Mr. Hurley avoids not only Government ownership or operation—he asserts that he means in his plan to secure the benefits of private enterprise—but also avoids the public-private corporation, a device much discussed with regard to the railroad problem, but one whose dangers we do not yet know. By avoiding these two evils, as well as that of wholly uncontrolled private operations, he offers a system well worth the attention of those who are formulating or are considering railroad operating plans. Perhaps it may even turn out that the finally successful railroad and shipping plans will both be devised as the result of joint study of the two problems.

As to terminals, it is necessary to observe that no provision whatever has been made by Mr. Hurley for ship terminals abroad. This is a defect, it would seem. He says that he desires to give the small ship operator a chance, since only thus can the industry be developed to size and strength. Yet if the small ship operator is to be put in position to make a fight for business

and hold it, he must in many parts of the world be aided in securing port and terminal facilities. It may be that terminals are a detail which will develop in the working out of the plan. We prefer, however, to regard it as a major question. Involved as it is with the subject of international relations, machinery additional to that which Mr. Hurley has conceived will be needed to take care of it. The need for this machinery may be short-lived, since ultimately the question of terminals should adjust itself; but during this temporary period we conceive that terminals will be vital in the development of our foreign shipping business.

Shipbuilding, finally, is a matter to which Mr. Hurley's plan gives no attention, and the shipyard man is left without encouragement or prospect as to anything beyond the current year. Stability in shipbuilding is closely inter-related with stability in shipping. So far we remain in the stagnation of thought which the Shipping Board created last fall. A plan for future shipbuilding is as important a need as a plan for ship operation, and the two should probably be combined. Full shipyard efficiency can be brought about and maintained only by reasonable assurances concerning the future.

Food for Thought in a New York Engineers' Meeting

LAST week's meeting in New York to discuss the engineer as a citizen offered food for thought, not so much in what was said by the speakers designated to open the discussion as in the thoughts offered in discussion and the ideas to which they naturally give birth. A movement was started to organize a New York local engineering society. There was some plain talk, such as is seldom heard in what the chairman called the "temple of engineering," while it remained for the floor discussion to face clearly the engineer's responsibility as to the most pressing questions in our social unrest. A brief account of the meeting will be found in the news section of this issue.

First, it may be said that there should be no delay in bringing to an early conclusion the purport of the resolution to establish a New York local engineering society. With all our talk about the engineer standing up and having his say on civic matters of an engineering character, the engineers of the country's largest city have remained unorganized and inarticulate. In stringent cases the central administrations of the national societies have bestirred themselves, but they have acted out of their natural sphere when they did so. Moreover, with their primary function one of national service, it is futile to expect them to follow closely and act on all manner of local questions.

As to the opening discussions at the meeting, none of them brought out in any adequate way the chief opportunity and the chief responsibility of the engineer in our present era of dominant industrialism, nor took up and handled conclusively the labor sore spots in our present crisis. Several of the speakers called upon the engineers to withstand the wave of Bolshevism should it break on our shores, but none of them analyzed the cause of Bolshevism nor pointed out the industrial measures that can cure the disease. It remained for one of the audience, Lieutenant Van Gilder, to point out the need for impartial study of this phase of the question.

The responsibility is so obvious that it is all the more remarkable that the subject was not handled fully and convincingly. The present industrial order is the creation of engineering. It is a mechanism by which labor is directed more or less intelligently and efficiently in the creation of things that satisfy human wants. In our conception of industrial economics we recognize two main elements—materials and labor. As to the first, we have left and are leaving nothing undone within the limits of human knowledge to determine all factors that affect their efficient use. In fact, we are constantly pushing out the bounds of human knowledge, by research work, that we may still further increase efficiency in the use of materials.

As to the other factor, labor, we have done relatively little. Taylor, and those who have followed him, have been building up a science of management, but relatively few competent men are engaged in the task. Furthermore, all but two or three set narrow limits to their inquiry and are interested in the efficiency of the worker only while actually at his task or machine. Yet back of that is a host of factors—human factors—that condition his efficiency. These factors—health, housing, the stimuli of sustained interest, the share in the value of what is produced, etc.—all need to be attacked with the clearness of the engineer's vision. They are being attacked, but by long-haired reformers, by rabid leaders, and the results have been far from wholly good.

Scientific principles and mathematical formulæ now in existence may be of no avail for instant application to these human problems, but the elements can be clarified by the impartial examination that is fundamental in engineering inquiries.

Of the plain talking, the most interesting was Mr. Johnson's sharp criticism of the type of men elected to office in our national engineering societies. He described them as men who had won reputations and were afraid of damaging them by starting something new. His analysis may be partly true, but in the general import of his remark—that we elect men to office rather to honor them than to secure for the society services that will really be of value—we heartily concur. "Young men for war, old men for council." The conduct of a worth-while society requires both types. Action is needed, but action tempered by experience. Now, however, the experience is dominant; there is so much counsel that action is inhibited. In business we put the older men in the directorate, but the department heads, who get action, who originate new ideas and methods, are young men. In societies the secretary must be of the action type or have active men under him, and in the board he needs supporters of the active type as well as counsellors of conservatism. Above all, there is needed, every other term, a president selected for the service he is able to render the society rather than for the honor which the society can confer on him.

Mr. Johnson's views are good food for thought for nominating committees.

Finally, a remarkable thing about the make-up of the audience was that it was composed three-fourths of the distinctly younger men. Gray heads and bald heads were in the minority—an indication that the generation coming into power will concern itself more with the engineer's responsibility as a citizen than did the past.

Solving Construction Problems in Canal Street Subway

High Ground-Water Level Complicated Deep Construction Work Under the Old Subway in New York City — Pit and Drift Methods Used

By A. J. Mayell

Assistant Division Engineer, Public Service Commission, New York City

Unusual methods were adopted in the solution of several problems which developed during the construction of the short section of the Canal St. subway in New York City, between Broadway and the Bowery. The primary cause of the adoption of these unusual methods lay in the difficulties due to the high ground-water level, and led to the process adopted, which consisted essentially in digging square pits as deep as the ground-water level would permit, lowering the ground-water level, excavating the cut, extending the pits to lower levels, and concreting them. Under the Centre St. loop, drifts were used in three levels, provision being made to set forms for wall and skew back of the roof arch as the drifts were widened out in 8-ft. sections. Considerable leakage developed at the points where overhead lap joints were made in the waterproofing. This has been reduced by forcing grout under pressure through holes drilled in the concrete.

The street surface of Canal St., from Broadway to Centre St., is only from 10 to 12 ft. above mean high water, and the normal level of ground water is only slightly below mean high water. The first problem involved the lowering of ground water sufficiently to permit building the structure. While normal ground water was only slightly below mean high water, as stated, pumping in the vicinity, by other contractors, had lowered the ground-water level about 15 ft. before the construction of the Canal St. crosstown line, known as Sec. 2, Route 20, was started. The lowering of the water from elevation —15 to —35 was accomplished by continuous pumping from three sumps and two well-points with 3-, 5- and 8-in. centrifugal pumps.

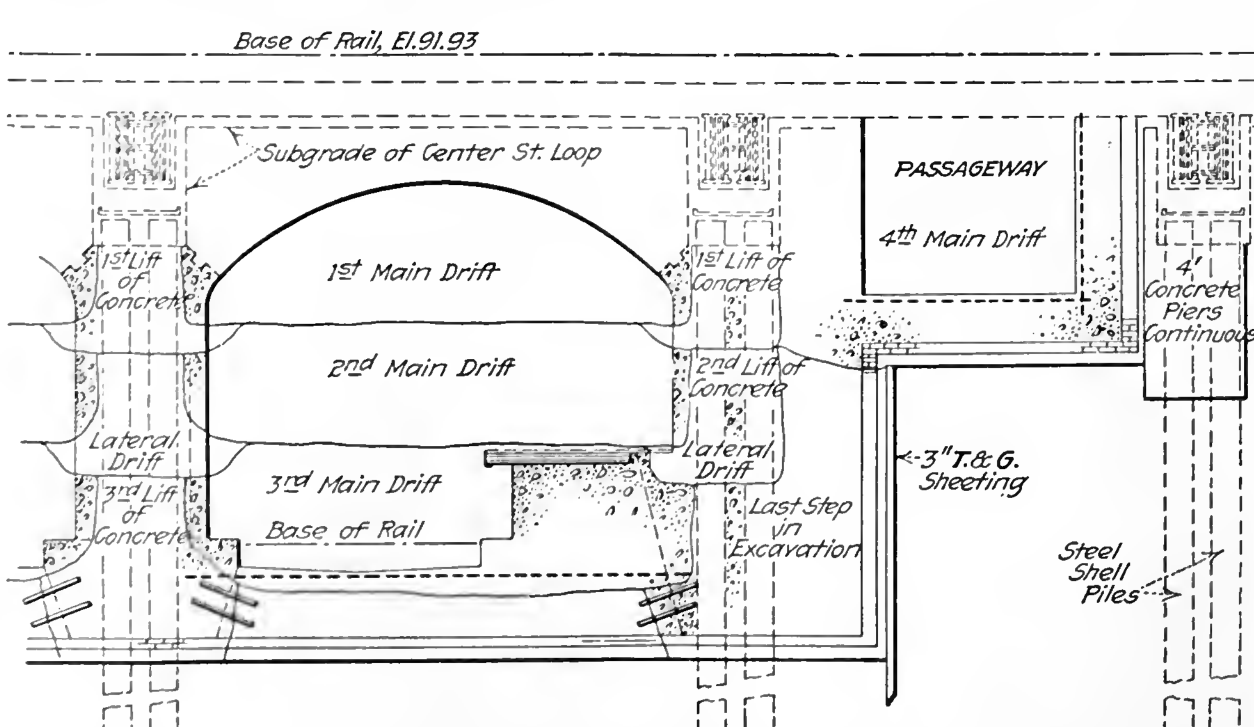
Protection of the buildings along Canal St. from damage due to settlement was accomplished in an unusual manner. Instead of underpinning the buildings, the contractor protected them by means of a continuous concrete wall constructed by the "pit" method, which may be briefly described as follows:

Attacking the work from three shafts, one just east of Broadway, one between Lafayette St. and Centre St., and one at Harry Howard Square, the contractor removed the top lift of the excavation to a depth of about 10 ft. for the full width of the cut. Pits 4 ft. square, spaced 4, 8 or 12 ft. apart were then excavated on the neat lines to such depth as ground water would permit, and filled with concrete. Intermediate pits were then excavated and concreted, until the piers formed a continuous concrete wall 4 ft. thick along each neat line. The needles across the cut supporting the timbering, pipes and street decking either butted against or were recessed into these piers.

In the meantime, pumping from the sumps had been started, and ground water lowered enough to allow excavation to within a few feet of the bottom of the concrete wall, when the process of extending the wall to a lower level was started. This was done by undercutting the wall in 4-ft. sections and excavating these pits to such further depth as the lowered elevation of the ground water permitted. These pits were so spaced that not more than 4 ft. of the wall in every 12 ft. was undermined at one time. After the pits were concreted, the intermediate pits were excavated and concreted, and the process was repeated until the entire wall was extended to this lower level.

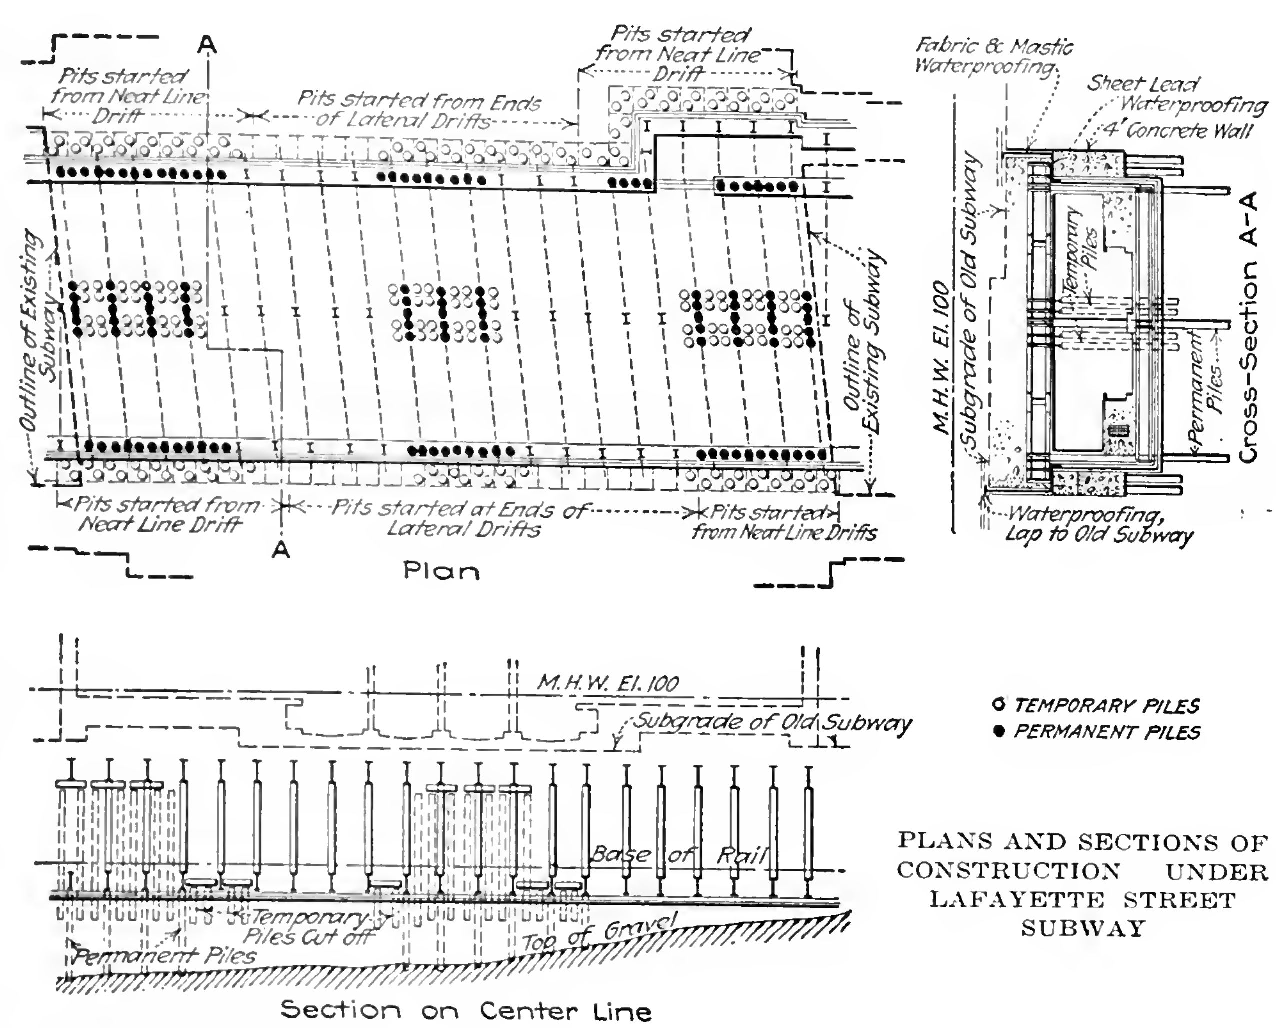
This process of lowering the ground water, excavating the cut, extending the pits to lower level, and concreting them, was repeated until the excavation was within a few feet of subgrade and the cut was protected with a continuous concrete wall on both sides. East of Centre St., where the ground water was lowered below subgrade, the wall was extended a few feet below subgrade, while west of Lafayette St., where lowering the ground water the last few feet was a slow operation and where poor soil conditions were encountered, steel sheet piling was used for the bottom four or five feet.

These concrete walls not only took the place of sheeting but also, with certain additional bracing across the cut, acted as protection for the buildings. As the contractor was entitled to unit-price payment for protecting buildings, and as most of the sand used in the concrete was taken from the cut, the cost of constructing these walls was considerably less than would have been the cost of sheeting the cut and underpinning the buildings.



CONSTRUCTION OF SUBWAY UNDER CENTRE STREET LOOP IN THREE LIFTS

Another problem was the construction of the new subway under the existing subway structures in Centre St. (Centre St. loop) and in Lafayette St. (Interborough subway). When the Centre St. subway was built in 1910-11 the loads were carried to heavy floor girders which, in turn, were supported on steel shell piles driven below the subgrade of the proposed crosstown subway, so that the construction under Centre St. was not a very difficult matter, but the method adopted was somewhat original. The plans called for concrete arch construction over the tracks, and in order to make progress, and still not wait for the ground water to be lowered to subgrade, drifts about 10 ft. deep were excavated along the center line of both tracks of the crosstown line. These drifts were widened out to expose the piles, but the material around the piles was removed in 8-ft. sections at a time.



PLANS AND SECTIONS OF CONSTRUCTION UNDER LAFAYETTE STREET SUBWAY

As each 8-ft. section was uncovered, forms were set for the wall and the skewback of the arch and this section was concreted. This method was continued until the entire center wall with the skewbacks of the arches and the portion of the 8-ft. sidewalls inclosing the piles were concreted to a depth of about 6 ft. The excavation was then deepened in 8-ft. lateral drifts, and the next lower section of the walls was concreted. The top board of the forms was inclined outward and extended above the bottom of the wall already placed so as to permit placing the concrete under a slight head. The horizontal joint between these pourings was grouted after the concrete had set and settlement and shrinkage had taken place.

USE OF 8-FOOT SECTIONS IN CONCRETE CENTER WALL UNDER CENTRE STREET LOOP

Excavation was then continued to the bottom of the wall as placed, and again lateral drifts were excavated, this time to subgrade, and the bottom protection concrete and brick-in-mastic waterproofing were placed. Then forms for the bottom section of wall were placed and concreted. The remainder of the excavation was then removed and the invert placed.

The reason for constructing the walls in 8-ft. sections was to avoid placing entire dependence for the support of the overhead structure on the piles, which would have resulted if the material around the piles had all been removed at the same time.

The method of construction under the old subway in Lafayette St. was more difficult, as no provision had been made when it was built to support it during the construction of the crosstown line. The first operation was to excavate a drift about 8 ft. wide and 8 ft. deep under the old subway along the center line of the crosstown line. This drift was carefully sheeted and braced across with timber struts top and bottom. Under the center line of the Lafayette St. subway a lateral drift was then excavated from the center drift to points about 4 ft. outside the north and south lines of the crosstown line. At the ends of this drift, pits 4 ft. square were sunk, with horizontal sheeting to the ground-water level, and concreted. Two ply of sheet-lead waterproofing were then placed over the top of the concrete piers, and protected with a layer of cement mortar.

The first roof girder was then brought in through the center line drift and placed in the lateral drift in its final location, resting on blocking on the soil, the ends being supported on the concrete piers at the ends of the drift. The roof girders were ordered in three sections so that they could be handled in the drifts, and were spliced after being placed in position.

A 4-in. wall of concrete was then placed at the ends of the drift, a strip of the protection concrete on the bottom of the old subway was removed, and three-ply waterproofing fabric mopped with coal-tar pitch was placed on the protection wall and carefully lapped onto the brick and mastic waterproofing on the bottom of the old subway. The lower end of the fabric was dovetailed with the sheet lead previously placed on top of the concrete pier. About 1½ in. from the fabric a brick wall was erected, and the pocket thus formed was filled with mastic.

Forms were then set 3 ft. each side of the girder, and concrete was placed around the girder about flush with the top of it, keys being left in the concrete and rods being placed to bond it with the adjoining concrete to be placed later. After the concrete was set, posts and caps were placed on top of the girder and wedged up to support the overhead structure.

Another lateral drift was then excavated adjacent to this, and the same operations were repeated; a third drift was excavated on the other side of the girder and this operation was continued, with drifts alternating east and west of the first. The space between the top of the girders and the bottom of the old subway was placed by hand and packed well with rammers. Grout pipes were placed longitudinally with "tees" looking up in each bay for the purpose of grouting during construction, and vertical pipes were placed in each bay for final grouting after the entire roof was placed.

Steel Shell Piles Support Roof

After several roof girders had been placed and concreted, the center line drift was deepened to permit jacking of steel shell piles to support the roof construction while the core of excavation was being removed. Four rows of 12-in. steel shell piles, two rows on each side of the center line, spaced so as to avoid interference with the center line columns and the transverse steel, were jacked in place. These piles were in sections from 5 to 7 ft. long; the material inside the piles was cleaned out as the piles were driven, additional sections being added and held in place by an interior collar. When the piles reached a depth of about 2 ft. below subgrade they were concreted and tested. Jacking was continued until the pile showed no settlement under a test load of 70 tons.

The piles were capped with short pieces of channels, and 15-in. I-beams were placed spanning from a pile on one side of a roof girder to one on the other side, and wedged up with steel plates and wedges under the bottom flange of the girder.

Drifts had in the meantime been started under the concrete wall formed by the piers at the ends of the lateral drifts. Pits 4 ft. square were excavated under the wall, and piles jacked below subgrade, similar to the piles in the center drift; the piles were concreted and tested and the pits concreted and sealed.

The remaining core of excavation was then removed to the base of the rail. On account of the poor bearing power of the soil, it was decided to have additional piles driven directly under the floor girders. Four additional piles were then jacked down to bearing on a stratum of gravel varying from 6 to 12 ft. below subgrade under each floor girder; one pile being directly under the center-line column and two on each side of the center line; under the side walls one pile was driven under each girder and two were driven between each pair of girders.

After these piles were driven the floor girders were placed and brought to bearing on the piles by means of steel plates and wedges. The temporary piles were then cut off, sealed with asphalt and capped with steel plates, and I-beams were placed on top of them between the floor girders, and posted to the roof. The floor was then waterproofed with brick and mastic, and concreted, boxes being placed around the posts on top of the I-beams. After the concrete had set the posts were removed and the boxes concreted.

EXTENDING PITS TO LOWER LEVEL ALONG NEAT LINE OF CUT

The maximum settlement in the overhead structure was 2½ in. in the track columns and 3 in. in the platform columns. About a year after the structure was completed and put in operation and the ground water had returned to its normal level, considerable leakage developed in the new structure. The leakage appeared wherever an overhead lap had been made to the waterproofing of an overhead structure; namely, under the Lafayette St. subway and in certain stairways where connections had been made to the Centre St. loop station. It was thought that a slight settlement had taken place in the mastic waterproofing, and the laps had pulled away enough to permit the entrance of water underhead.

The remedy suggested was to drill holes through the interior concrete in the direction of these laps and force a thin mixture of grout into the holes, under enough pressure to seal the openings. This method has been tried and has proved very effective, the leakage having been reduced from about 150 gal. per minute to less than 5 gal. per minute. The grouting is not yet finished, but it is believed that the leakage can be entirely stopped and the station made absolutely dry in consequence.

The Underpinning and Foundation Co., was the contractor for the construction of this section of the subway.

Effects of Insufficient "Curing" Period in Water Softener

Incrusted filter sand, limed-up meters, coated service mains and persistent troubles with hot-water heating apparatus, all in greater or less proportions, are the result of an insufficient detention period in the settling basins of the Grand Rapids, Mich., water-purification plant.

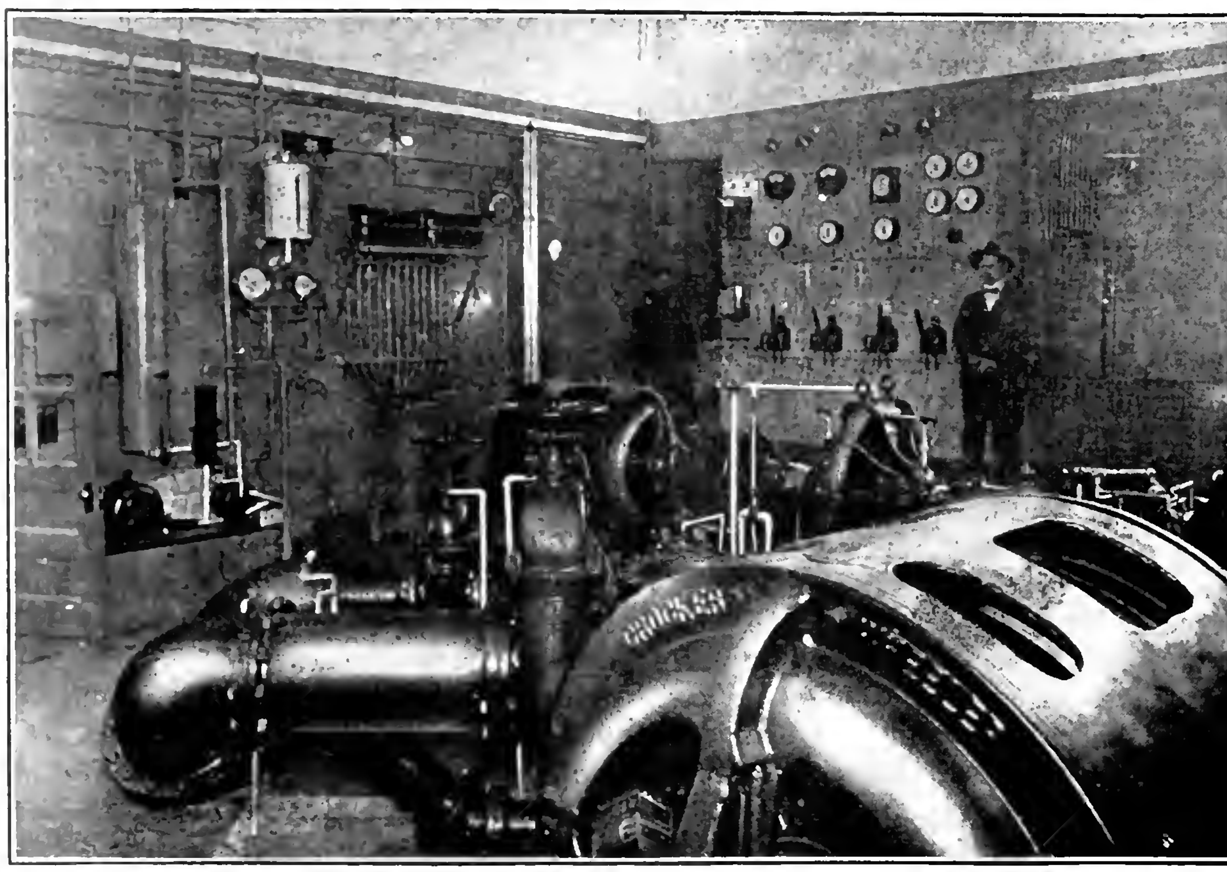
Details were given by W. A. Sperry, chemist of the filter plant, at the recent meeting of the Illinois section of the American Water-Works Association. Comparing the sand as placed in 1912 with analysis made in August, 1918, the effective size had increased from 0.27 to 1.05 mm.; the uniformity coefficient had decreased from 1.61 to 1; the thickness of coating is now 0.255 mm. Intervening increases were given in *Engineering News-Record* of May 10, 1917, p. 304, and Aug. 22, 1918, p. 358. Classifying the troubles found with the 3827 meters, out of a total of 22,000 meters, sent to the shop during the year which ended July 1, 1918, 53.9% were limed-up only; 12.1% had lime and mechanical troubles; 19.3% mechanical troubles only; 8.1% were frozen; 1.5% sand clogged; 0.2% taken out for test; 0.1% found all right, and for 4.8% there was no information.

Design of New Electric-Drive Water-Pumping Station Was Governed by Power Rate

Current Charge for Three Months Depends on Maximum Use in Any Two-Hour Period—Universal Meter System Postponed Because Temporarily Cheaper to Pump More Water, but Expected to Come Later

By Henry W. Taylor
Consulting Engineer, New York City

DEVELOPING a new pumping station for the water-works of Cohoes, N. Y., from 1914 to date, involved unusual conditions as to water consumption, change in power, power rates and changes in design. The chief controlling factor has been the rate for electric power. This has reacted on pump capacity and has caused the temporary postponement of the introduction of a universal meter system. In 1914 the water-works were in charge of a water board under the old city charter. The pumping plant consisted of three reciprocating pumps, driven by two water turbines, and one electric-drive centrifugal pump, which was used during low-water stages of the hydraulic canal. All of the equipment, except the electric-drive pump, was from 20 to 30 years old and was in a condition requiring constant repair and subject to unexpected breakdowns. Mechanically, the equipment needed replacement, in any case, on the basis of safety and economy.



THE TWO LARGER PUMPING UNITS, PRIMING OUTFIT AND SWITCHBOARD OF THE COHOES PUMPING PLANT

In 1914 the Cohoes Co. was still operating the old hydraulic canals which were serving the individual lessees of property along these canals and providing water for power. The old scheme of hydraulic canals resulted in an uneconomical use of the total water power available from the Mohawk River, and the Cohoes Co. was, in 1914, developing a scheme for the installation of a central hydro-electric generating station which would use all the water available from the Mohawk River under a maximum head and with maximum efficiency. The mill owners were to be supplied with electric power which was to supplant the water power previously provided them. Such a reorganization, affecting many different types of mills and a multitude of owners, involved a considerable amount of time, but eventually, special contracts were agreed upon which made a central power station possible. Thus the hydraulic power was eventually supplanted by electric energy.

The city pumping station represented one of the properties which had heretofore used hydraulic power, and the water board must necessarily look forward to a change in its pumping equipment for electric drive. In 1914, the question of contracts was still unsettled, but it was supposed that the best rate which could be obtained in the new arrangement would be about $\frac{3}{8}$c. per kilowatt-hour for night pumping.

The water consumption at Cohoes approximated 225 gal. per capita per day in 1914. Metering was brought to the attention of the board, but was temporarily rejected on the basis of certain peculiar conditions involved in metering the city. Without meters it was found that, at certain times during excessively cold or hot weather, the water consumption frequently ran to from 8,000,000 to 10,000,0000 gal. a day. The normal daily consumption was from 5,500,000 to 6,000,000 gal. Without meters it could not be expected that this rate of consumption would be materially decreased; while, on the other hand, provision must be made for its material increase. The further requirement that pumping must be done on a 12-hour basis to secure the advantage of the better electric-power rate necessitated a pumping station having a capacity twice that of a 24-hour plant. It was therefore decided to abandon the present pumping station and build a new station containing three 10,000,000-gal. units, consisting of centrifugal pumps with direct-connected motors and accessories.

Complete plans were drawn for such a scheme. They involved a new pump house, a new house for the superintendent of the pumping station and a new water intake, suction wells, piping and electrical equipment inside the pumping station, together with a new force main which was required to supplement other force mains to accommodate a pumping rate per 24-hour day of 20,000,000 gal. The three units provided for one reserve unit while the other two units would be run together for a 12-hour shift.

In 1915 the city charter was revised and the office of commissioner of public works was created. The commissioner became the head of the water bureau. The question of metering was thereupon taken up with this official, and a scheme was developed whereby a pumping station could be erected in connection with the installation of meters. This would be much more economical in the end, and for its housing a portion of the existing pumping station could be used. The question of meters was taken up with a citizens' committee, and the whole plan of the combined meter and pump installation was finally accepted as the proper method of development.

Current Charge Based on Two-Hour Maximum

During 1916 and the early part of 1917 efforts were made to close a suitable electric power contract with the Cohoes Co., which would allow adequate credit for leases held by the city for the use of the old hydraulic canal. This contract was closed in the early part of 1917. The main point of interest in this contract, exclusive of local complications, is an electric rate of $20 per kilowatt-year, or about 0.228c. per kilowatt-hour, and the provision that the amount of current charged against any given quarter would be represented by the continuous use for that quarter of the maximum amount of current used during any continuous two-hour period.

In the autumn of 1916 contracts were let for remodelling a section of the present pump house to receive the new electric-drive pumping apparatus and for the first installment of meters, these meters being recommended in size and number to serve the principal industrial and commercial needs of the city. It was hoped that this first installation of meters would reduce the consumption by at least 1,000,000 gal. a day and that the future additional meters would bring the per capita water consumption down to about 135 gal. a day.

A definite electric-power contract having been made, meters purchased and a meter system adopted, it was possible to design a pumping station which would best suit the water-consumption and electric-power requirements in the case. In 1916 the average daily consumption ran to about 9,000,000 gal. a day during continued periods of cold or hot weather. The raw-water reservoir to which the pumps deliver had a storage of about 45,000,000 gal. which could be delivered to the filtration plant. It was assumed that the first installation of meters would be completed before the pumps could be placed and that in the meantime the excessive use of water during hot and cold periods would be materially reduced and the average consumption for the year would approximate about 5,000,000 gal. a day. The electric contract required, for economical operation of the plant, that the water pumped per day be as close as practicable to the consumption, since one day's pumping of an excessive quantity of water would create a power record of over two hours and this day's use of power would be the basis of the charge for the entire quarter irrespective of the reduced power used on subsequent days. The normal consumption of 6,000,000 gal. a day was to be reduced, and, in view of the storage of raw water available, it was considered that a normal maximum capacity of 7,000,000 gal. a day would be ample.

To meet the decreasing use of water due to the use of meters it was important that the units making up the plant should be graded downward, and it was decided to install three pumps, one of 1,000,000-, one of 4,000,000- and one of 6,000,000-gal. capacity. This combination of units made it possible to pump 4, 5, 6 or 7 million gallons per day by various combinations or an average of 4½, 5½ or 6½ million gallons per day.

It was also considered advisable to have the larger pumps of a characteristic curve such that when the 4,000,000- and the 6,000,000-gal. pumps were operating together they would not give their combined capacity but react against each other so as to yield about 7,500,000 gal. per day. In case these two large pumps were used together, inadvisedly, for a period of more than two hours, there would not then be an electric charge for a whole quarter resulting from pumping 10,000,000 gal. for a short period, and with a meter system the pumps designed provided ample capacity and ample reserve for many years to come. Population increase would be balanced by per capita reduction in the use of water, for which there was ample margin.

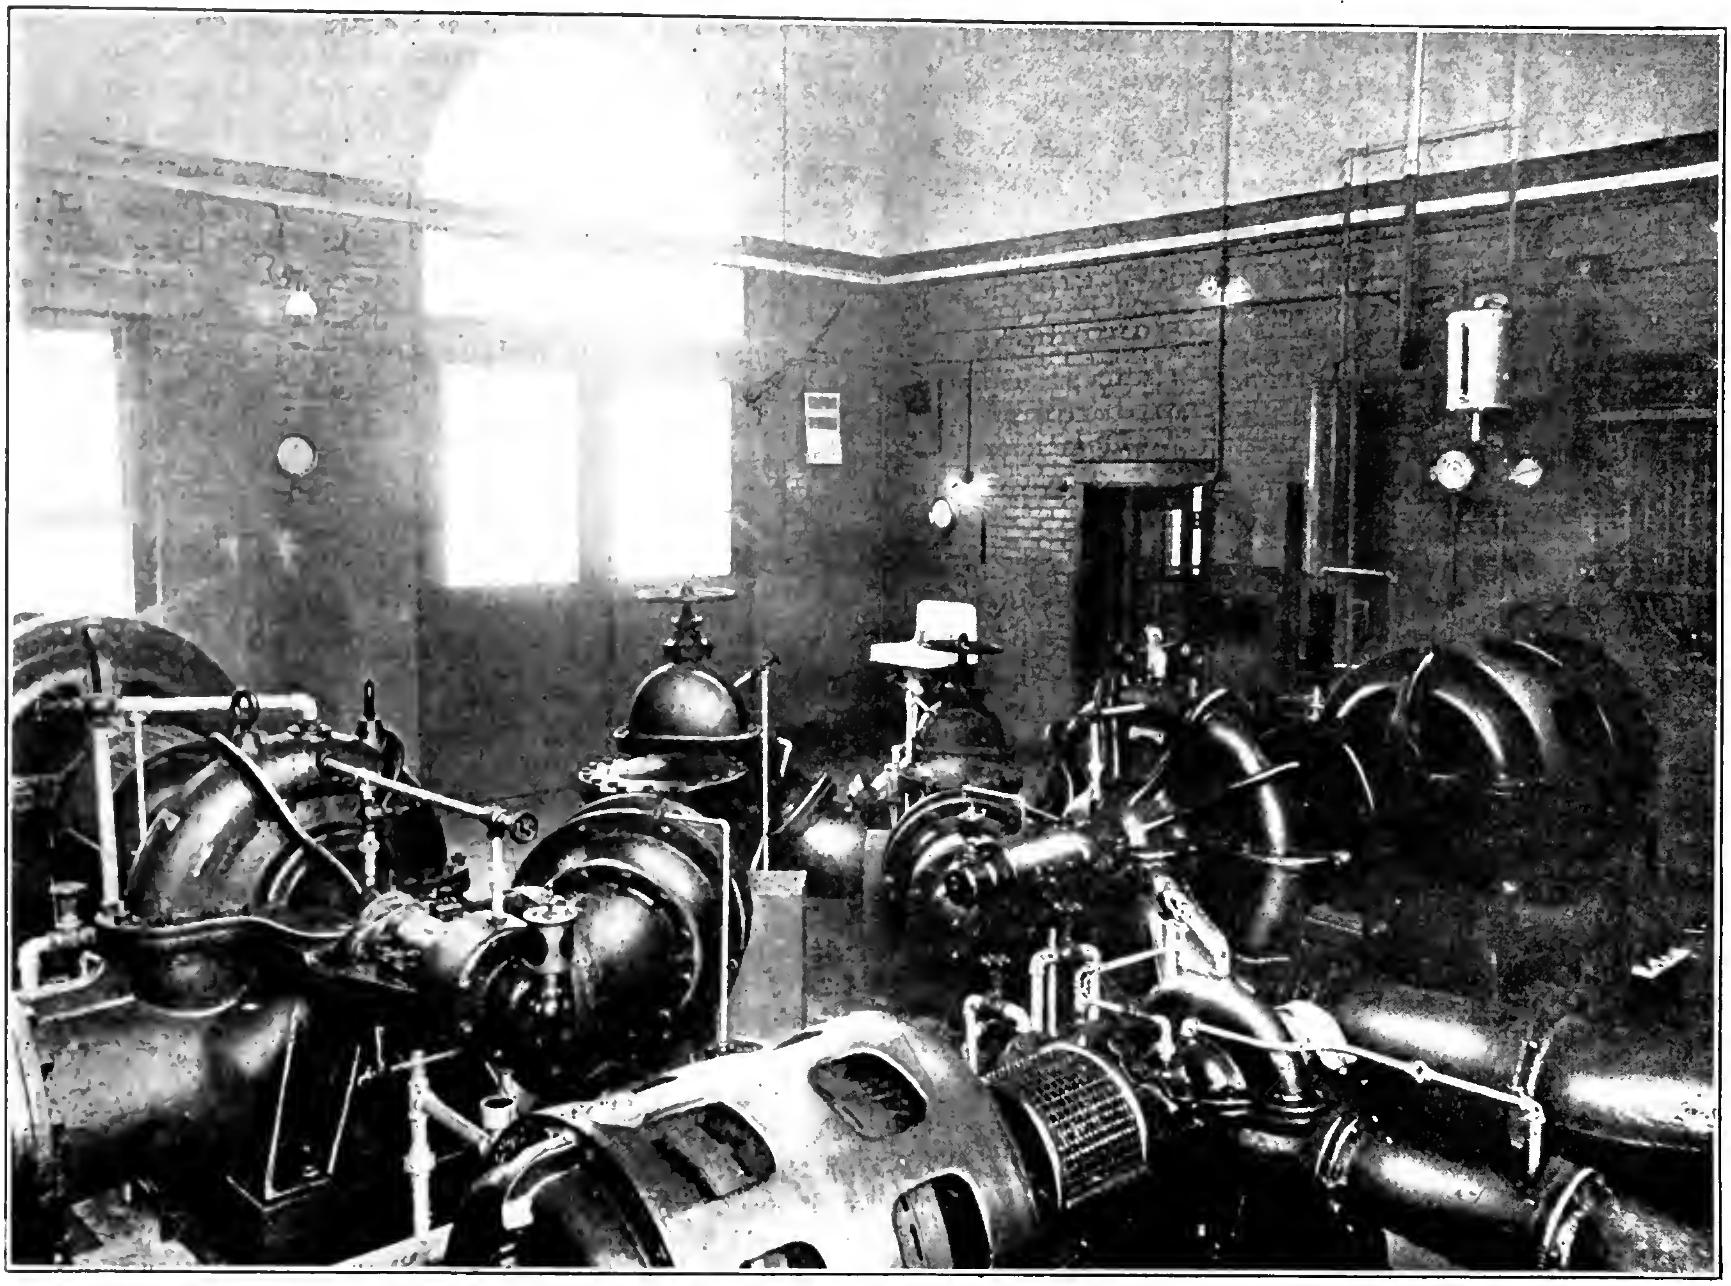
In designing the plant it was necessary to bring the discharge of the pumps to an existing elbow in the floor, which was embedded in a masonry arch and could not be disturbed. In order that the discharges could be separately valved, the parallel layout of the piping shown in the photograph was required with a true 16-in. Y having the inlet flange turned down to a diameter which would be received by the bell of a 20-in. pipe. Flexible joints were installed for the larger pumps, so that no undue strain would be transmitted to the pump castings. There are no gate valves or check valves on the suction lines of the pumps, but the pumps are primed by means of a rotary vacuum pump driven by an electric motor, with long-distance controls at the compensator starters for each pump motor. The air in the suction lines and the pump casings is exhausted by means of this vacuum pump. A small tank with a glass gage indicates to the operator when the suction lines and pumps are full of water. The vacuum pump is then stopped by the pushing of a button, and the motors are started. The motors are slip-ring motors, and a special interlock was installed in the compensator starters which makes it impossible for an operator to throw on the main switch of a motor if the compensator is in the "full-on" position. It is thus impossible to throw the full voltage across the motor in the operation of starting it.

Old Turbine Pit Made Into Suction Well

The suction well sumps consist of an old water turbine pit to which the water passes through float-operated butterfly valves. An electric-alarm float indicator also shows the operator the water level in the suction well and gives the alarm for high and low water.

A wall crane with a 24-ft. reach and containing a trolley and hoist is to be installed for removing the upper half of the pump casings, motor armatures, etc. The station is equipped with a full complement of electrical and hydraulic indicating instruments mounted on the electric switchboard and on the individual unit panels.

The three motors are 2300-volt, two-phase, 40-cycle machines. The two 4,000,000- and 6,000,000-gal. pumps are single-stage, double-suction, operating at 1170 r.p.m. against a total head of from 170 to 195 ft. The 1,000,000-gal. pump is single-stage, double-suction, running at about 2300 r.p.m. against a total head of about 185 ft. at full capacity. The small vacuum pump is operated by



THREE ELECTRIC-DRIVE PUMPING UNITS WORKED IN VARIOUS COMBINATIONS DELIVER WATER TO COHOES
The 1,000,000-gallon unit is in the foreground, the 6,000,000-gallon at the left and the 4,000,000 at the right of the view.

a 2-hp. motor and is capable of developing a 24-in. vacuum. By means of this pump any unit may be brought from rest to full pumping load in about 45 seconds.

The arrangement of the pump may be called radical. The large pumping units have center lines at right angles to each other. This leaves the motor end of the unit in a free space with no electrical apparatus adjacent to it and provides free access to all sides of both machines. Water from the pumps is deflected by a 45-degree fitting to the force main header which runs above the floor on the center lines of the pump discharge openings.

In the process of removing the old apparatus, and, due to lack of water in the hydraulic canal on Sundays, the level in the raw-water reservoir was considerably reduced. At the same time it was apparent that the consumption of water would average at least 7,000,000 gal. instead of 6,000,000 or 5,000,000 and, owing to lack of meters, the average requirements of the pumping station were unexpectedly increased.

The engineer realized that to meet this unexpected demand it would be necessary for the 6,000,000- and 4,000,000-gal. units to operate together to give a total pumping capacity of about 8,500,000 to 9,000,000 gal. A defective runner in the 6,000,000-gal. pump was replaced by a new runner, and in supplying the new runner the manufacturer furnished one with different characteristics, so that 6,000,000 gal. could be pumped against 180-ft. head. From this point backward the characteristic curve would rise as rapidly as possible and deliver as large a quantity of water as might be, against an increasing head, up to 200 ft. This runner was received and was found to operate successfully with the 4,000,000-gal. pump so as to produce a total quantity, against about 195 ft. of 8,500,000 to 9,000,000 gallons.

Lack of meters required this change in the pump design, and increasing consumption placed a load upon the pumping station such that continuous operation during periods from two to four weeks of both the 6,000,000- and 4,000,000-gal. units together would be required. As these facts developed, it was apparent that the reserve in the original design of the pumping station would be seriously impaired, and a reserve unit has been purchased.

The low cost of pumping water produced an unusual condition, affecting the question of metering as against pumping more water. A given number of meters would reduce the consumption of water by 1,000,000 gal. a day but it would cost only $700 per year to pump an additional 1,000,000 gal. Additional pumpage is temporarily cheaper. The metering policy, however, must eventually be adopted in order to prevent the impairment of the capacity of the existing reservoirs, the filtration plant, the force mains and the main conduits delivering filtered water to the city, and of existing pressures. Meters will doubtless be installed after a suitable educational campaign. The writer has been consulting engineer for the Cohoes water-works since 1914.

With the Divisional Engineers in a Great Offensive

What the Fighting Engineer Troops Had to Do When They Went Ahead Day by Day With the Infantry

By Charles E. De Leuw
Gates & De Leuw, Engineers, Chicago
(Late Captain, Engineers, United States Army)

ENGINEERING in the great war was so largely a matter of preparing for the actual fighting, and so great a proportion of the American Army engineers in France was engaged in the splendid work of the Service of Supply, that many in this country have never learned just what was the work of the engineer troops in the zone of advance. Censorship restrictions, too, did not permit those combat units much publicity. The writer was privileged to serve through the last months of the war with the Fourth Engineers, a regiment operating with the Fourth Division, in contact with the Germans, and his experiences there may give some indication of what the divisional engineer had to do, though no one man could have accurate first-hand information of any other than his own regiment.

Each infantry division contains an engineer regiment and an engineer train. The regiment proper consists of six companies, each with 250 men and six officers, and the headquarters detachment of 119 men. The engineer train contains both motor- and horse-drawn vehicles, and, in addition, each company is supposed to have four engineer tool wagons, two motorcycles, eight pack mules, the company supply wagons, rolling kitchen, and mounts for the officers. In service in France, as a rule they had all of these except the pack mules and mounts. The colonel of an engineer regiment is division engineer and adviser to the commanding general on all matters pertaining to engineering or construction work. It is his duty to keep himself constantly informed as to the need for work in the divisional area and to dispose of his unit to take care of that work. Engineers—and, as a matter of fact, all other troops—are auxiliary to the infantry, and in this war they were armed, equipped and trained as infantry, and for such engineering service as they might be called upon to do.

Division Engineers' Part in Trench Fighting

In trench warfare, divisional engineers are charged with the layout and construction of trenches and wire entanglements, the maintenance and drainage of trenches, the construction of dugouts and deep shelters, all mining work, provisions for sanitation and adequate water-supply, and the maintenance of paths and roads leading to the trenches. Immediately after an advance, when a portion of the enemy's trench system has been captured, it devolves upon the engineers to consolidate the new position—in other words, to make such new construction as to render the trench tenable when facing what formerly was the rear. This always includes the immediate erection of wire between the occupied trench and the enemy. If the trenches are to be abandoned, the engineers' job is to demolish all structures which will be of aid to the enemy and to place as many obstacles as possible in the path to obstruct his rapid advance.

In open warfare, or war of movement, the engineers are charged with duties that are somewhat similar, but which are, in the main, less complex. In an advance they repair and build roads, bridges, cut barbed wire and lay out defensive lines; in fact, do anything and everything to facilitate the advance of the infantry and the steady and uninterrupted flow of munitions and supplies to the infantry and the artillery. In a retreat—something, fortunately, in which the American Army had little experience—the engineers' chief mission is to destroy bridges, roads, railroads, and water-works and place as many obstructions as possible in the way of the advancing enemy. In many cases it is necessary to bolster up the line by putting engineer units in as infantry, as was done in the famous repulse of the German advance near Amiens in the spring of 1918.

When Our Engineer Units First Saw Real Fighting In the Open

The campaign having its origin in the great counter-offensive of July 18, 1918, extending from Soissons to Rheims, was the first in which the American Army had a prominent part, and in this action the Fourth Engineers first saw real service. About 10 American divisions participated in this campaign, which was strenuous in every sense of the word. There our engineer units had their first taste of open fighting, and their portion, as well as that of all other troops, was tiring and ceaseless work. Hard fighting took place within the Chateau Thierry salient, but it was of comparatively short duration, and consequently the roads and other structures were not completely destroyed, and in places were practically untouched. The retreat of the Germans out of the salient was so hurried that only occasionally did they have time to destroy roads and bridges, all of which simplified the task of the engineers. Nevertheless, the fighting had torn up the roads and bridges to some extent, and occasionally the Boche engineers had had time to mine a road or a bridge, so our engineer regiments had plenty of work. On roads filled with shell holes there was usually enough stone nearby for backfilling. Where the road had been mined, débris and demolished masonry in the nearest village was hauled to the site, or, if this was impossible, sand bags were used, filled with the best material at hand.

The bridges were all over comparatively small streams, and if it were impossible to repair the structure, a rough bridge which would serve temporarily was thrown up. Time was the only consideration. For foot bridges for use of the infantry, convenient trees were sometimes felled across the streams. In addition to this repair work, the engineers had to outline defensive positions during the advance. It was very necessary to play safe at all times and have a position outlined behind the advanced infantry, so that in case of a strong hostile counterattack the infantry would have a position ready to occupy. In this case outlining a position meant taping out a trench system or its main elements, after a careful reconnoissance. The machine-gun emplacements were dug, and at least one line of wire was strung in front of the position.

The writer knows of no better way to convey an idea of the life and experiences of these engineers than by giving a few extracts from some daily notes, necessarily brief and sometimes abrupt, made in the field during the Chateau Thierry fighting.

July 13—Finished the rifle range for the — Infantry today and moved the company to this town, which is about five miles from the lines. Made a reconnoissance of our new

work this afternoon with the major, most of the time in a pouring rain. Our job is to build lanes and communication trenches from here to the front line for the French. We were pretty close and I saw the German lines for the first time. Our work will not be dangerous, for we will work on the exposed spots at night.

July 16—Knocked out a good day's work on the trench system today, pretty well fagged out tonight. C company had a couple of men wounded today near us, the first in the regiment. Understand the Boche made quite a heavy attack east of here yesterday; we could hear the firing of heavy guns very plainly about 10 p. m.

July 17—Tonight starts our first big adventure; we go over with the infantry.

July 19—We came here with C company yesterday morning under fire, but no casualties. C company has gone up to Hautvesnes to construct a defensive position and we are bivouacked by the side of a sheltered road just east of Vinly, awaiting orders. We are in the counter-offensive from Chateau Thierry to Soissons. Our division and the French have been going splendidly—advanced 9 km. in 30 hours with light losses. The French regiment to which we are attached took 450 prisoners and 70 guns yesterday. The Boche is on the run at this point, the attack being a complete surprise to him. The fighting is open, what trenches there are being a very light type. The night of the 17th-18th was the blackest I have ever seen. There was a hard rain and a thunderstorm lasting half the night. It made the task of moving large bodies of troops up to the line very difficult. The roads were frightfully congested, and in the inky darkness many units had a hard time getting to their positions. They all got there on time as far as I know, and the infantry, our infantry which had never been under any sort of fire before, jumped off on schedule time and waded right through; some of them had hiked 20 km. in that mess of the night before, too.

July 22—Am sitting in an oat field near a small patch of woods. The fields all around are full of shell holes, and small cemeteries are thick. We have moved twice since the 19th, each time toward Germany. Have been doing trench work and road repairs, and D company is certainly going in great style; the company has had only three casualties.

July 24—Our division is going back for a rest and to get replacements, some of the infantry having had heavy losses. Our regiment fared well—only three officers wounded, all of whom will recover, I believe. What casualties we had were all from shell fire. Since the 17th we have moved practically every day, have dug trenches and repaired roads at all hours of the day and night. The most interesting thing I have seen is the short, terrible bombardment, which precedes the artillery attack. We were coming in from work the other night with the artillery back of us, when all at once they cut loose. I happened to be up on a high hill where I could see our shells bursting on the Boche, and it was a great treat. It was 4:30 a. m., and I ran the risk of being caught in an exposed position at daybreak to watch it awhile. It was superb.

Repairing Roads "For a Rest"

July 26—We are taking things easy back here. The billet I am in has been occupied by the Boche. We are repairing roads and building kitchens for the division, coöperating with B company. The other four companies are working on a defensive position. We are doing this for a rest.

July 28—Moved from our billets this morning and are now about nine miles east of there in territory occupied by the Boche within 24 hours. It is interesting to see what pains the Boches have taken to make this woods habitable. They have a profusion of dug-outs, and in every way it looks as though they had intended to stay here all winter. They abandoned an immense quantity of material here, as they have all along the line.

July 29—Moved again this morning, and are now bivouacked in a big woods with the entire division. We are still corps reserve, and I understand we are in an entirely American corps, the first time one has been formed during the war. The regiment is all together for a change.

Aug. 3—The division has been in front for two days. We are again in a large forest, the Fôret de Fère, I believe. Repaired roads and bridges today, covering about 16 km. of roads. Cleaned the débris out of the streets of Fère-en-Tardenois this morning; it was an awful mess. On returning to our bivouac found orders to proceed to the Bois de Dole, about 15 km. north of here. Will have good supper and start.

Aug. 4—Moved up here last night, roads almost impassable in spots due to recent rains. My transport did not get through so I hiked back to locate it; impossible to get anywhere on motorcycle. On roads again today. My company has had no sleep in 60 hours and has hiked that many kilometers.

Aug. 5—Getting a much-needed rest here in the Bois de Dole. Two companies have gone up to put foot bridges over the Vesle River for the doughboys. Another company reported to the — Brigade and is in the line. My company is ready to move on five minutes' notice.

Aug. 6—Made a reconnoissance for an artillery bridge over the Vesle yesterday afternoon with the major. We timed it rather poorly, as the doughboys were just going over and it was pretty hot. The Boche were actually sniping with one-pounders.

Met Machine Guns, Shells and Gas

Aug. 8—Have been assembling material for bridge. It has been hot down there. We are bothered with machine-gun fire in addition to shell fire, and the mustard gas is pretty thick. Our infantry still in the line and going forward slowly; they are holding the road on the other side of the river now. Cannot begin to describe the inferno down in that river valley. The Boche counterattacked this morning; they were supported by a heavy barrage which we had to go through. Their attack fell down when it met our machine-gun fire. The enemy has made a genuine stand here; our advance will soon have to cease, as we are approaching a point where our men are too fatigued to continue the work incidental to an advance.

Aug. 10—We are putting up our bridge. As the infantry have been stopped about 300 yards beyond the river, there is no hurry for an artillery bridge, and we are taking our time. Work at nights and go back about 4 km. to rest during the day.

Aug. 11—Work on bridge called off. Reconnoitered for a defensive position in front of Ville Savoye, just back of the bridge site, this afternoon. Took my platoon commanders along. It is getting hot in the little valley where we are camped. The artillery back there call it Death Valley. Ordinarily it is fairly quiet, but this morning the Boche got our range and I was waked up by some Boche shells. Looked out and saw a frightful slaughter of horses; cannot understand why the artillery keep their animals up here.

Aug. 12—Ordered to resume work on bridge; practically completed job. Working strength of company down to one lieutenant and 65 men.

Aug. 13—Division relieved, for which I am duly thankful. Our casualties were not so heavy, considering what we went through, but they were heavy enough. We all have our eyes burned a bit from the mustard gas in the valley. Joined the regiment today, and are glad to be back where the shells don't drop very often.

Aug. 15—Made a long hike last night and we are again in the Fôret de Fère, well back from the front now. We go back three days' hike and then entrain—do not know where we go. Some damfool at division headquarters has conceived the idea of having the engineers entrain the entire division. I am attached to the — Infantry; will hike back with them, then load them up.

The great campaign on the Meuse-Argonne front saw vastly different conditions and problems to be met. Here "no man's land" had been in the same general locality for four years. The terrific fighting around Verdun in 1915 and 1916 had effaced most of the artificial structures, and had greatly changed the natural features of the topography. Where roads had not com-

pletely disappeared, they were covered with two or three feet of mud. The entire country-side was one mass of churned-up earth, trench material, stone, and débris of all descriptions. On the morning of Sept. 26 the engineers went over thirty minutes after the infantry. Their principal task was to get the roads in such condition that the artillery could be gotten over them and ammunition push up. The infantry drove the enemy back about 10 km. the first two days and left behind them the most desolate looking mess imaginable. Let the imagination go as far as it will, and it cannot exceed the facts in this instance. On one road there were three regiments of engineers filling up the huge holes with sand bags, working with their hands, picks and shovels, using anything and everything to get that road in shape for traffic. The congestion on that road was terrific, and the daily rains served to add to the difficulties. The engineers often turned aside from their road making to put a truck or piece of artillery, which had slid into the ditch, on the road again. All of this was done under a hail of shell fire from the enemy. As everyone knows, these handicaps were overcome, and the campaign was finally pushed to a highly successful conclusion.

Compares Principal Plans for Railroad Policy

Equitable Trust Company Digest Shows Unanimity of Purpose, With Government Ownership Almost Without Support

THE digest and comparison of proposed plans for a future railroad policy, shown on the opposite page, and prepared by the Equitable Trust Co. of New York, indicate that all of the plans advanced "seek, in their final analysis, an adequate transportation system affording first-class service at rates which will not be burdensome but still sufficiently liberal to put railroad credit in the aggregate on a high plane, and which shall make it possible to pay the employees good wages," according to the statement of the company. It is pointed out that Government ownership is found to be entirely without support except from the railroad brotherhoods.

In *Engineering News-Record* of Jan. 2, 1919, p. 18, L. C. Fritch, vice-president and chief engineer of the Chicago, Rock Island and Pacific Railway Co., advanced "fourteen points" which he considered essential to establishing a sound railroad policy. In *Engineering News-Record* of Mar. 13, p. 504, Mr. Fritch suggested a more definite solution of the railroad problem, basing his article on plans which have been presented to Congress.

In commenting on the digest of the various proposals, the Equitable Trust Co. says:

"In the first place, we find that Government ownership is almost altogether without support, except from the railroad brotherhoods as represented by their counsel, Glenn E. Plumb. The predominance of opinion is for private control under restrictions, designed to promote better, more efficient service than was possible under the old system. The extension of Government control to the five-year period proposed by ex-Director General McAdoo likewise meets with little favor. In opposition thereto, it is argued that it would merely postpone the date of determining a problem which must come up for solution sooner or later; that it would tend to make the return of the roads to their owners more difficult; that it would place them in such heavy debt to the Government that liquidation or refunding would be practically impossible, and that there is nothing in the railway problem which cannot be solved in twenty-one months as well as in sixty.

"There is substantial unanimity that mergers should be permitted when in the interest of the public, and that the issuance of securities should be subject to Federal control. The latter subject is closely related to the question of Government guarantee of capital, for if the Government is to undertake the assuring to the roads of a specified minimum return, it is only logical that it should have something to say as to the creation of new securities, and accompanying new capital investment. The plans of the Association of Railway Security Owners, of Paul Warburg, and of Director General Hines, all contain provisions for such guarantee. The railway executives do not suggest anything quite so specific, but insist that rates shall be adequate as well as reasonable.

"The rate question, which is perhaps the most difficult of all to determine, is variously approached. There is a tendency to concentrate the rate-making power in Federal authority without, however, entirely destroying the power of the state commissions. This is in line with the sensible policy of eliminating, so far as possible, the conflicts which are inevitable where there is dual authority, or where the Federal authority may be hampered and its orders nullified, by state action. There is, moreover, a sentiment in favor of an attempt to arrive at some precise figure which will represent equitable compensation to the security holders. Several of the plans contain suggestions for profit sharing with labor, with the Government, or with both, in case profits shall exceed this figure. Here we have the community of interest idea, which has received widespread application in industry, proposed for a new field—transportation. The justice and economic soundness of its adoption will scarcely be questioned, though there will doubtless be conflicting ideas to be reconciled in working out precise details. From the standpoint of the security holders, the important features of a guaranteed minimum return, together with a division of profits above a maximum, means at the same time the elimination of uncertainty as the possibility of reduction of one's income below a certain feature, and the loss of opportunity for very marked appreciation.

"In other words, it would greatly stabilize railway securities and minimize their speculative features.

Suggestions for Financing

"The views in connection with methods of financing the roads are not at all in agreement. Particularly interesting is the novel proposal of Mr. Morawetz, who advocates the refunding of all existing securities by means of a fixed and continuing proportion of debentures and bonds. This would apparently give the debentures a high investment standing, and would still leave the stock sufficient equity, together with the minimum guarantee of $2.50 per share by the Government, to assure it of an investment character only moderately tinged with speculation.

"The successful features of Government operation are not to be lost with the return of the roads to private control, if the ideas of several of the authors of the various railway plans are carried out. The joint use of terminals, the elimination of competitive features which yield no additional public service, such as separate ticket offices, almost identical passenger train schedules, etc., may be eliminated in the interest of economy.

Adjustment of Wages

"Some thought has also been given to methods of settling wage disputes. Three of the plans quoted aim to set up permanent organizations for the handling of these questions. Presumably a regular line of procedure for obtaining hearings and appeals would be instituted. If found workable, this would provide the machinery for proper consideration of, and decisions upon, this very vital matter."

PROPOSED RAILROAD PLANS

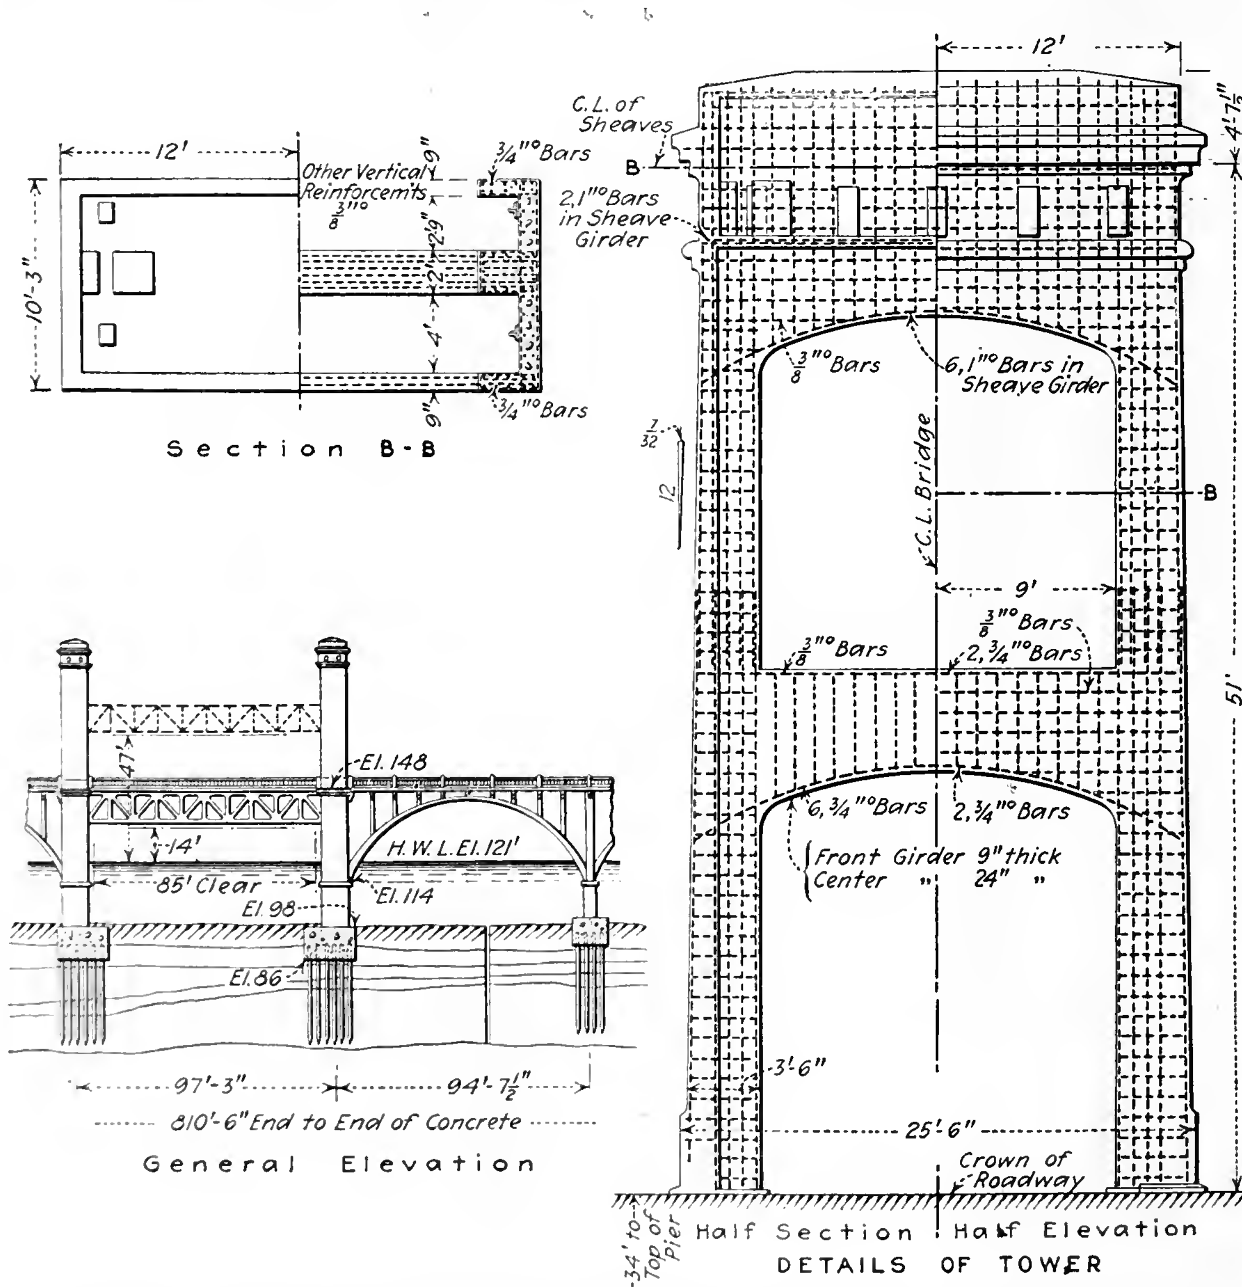
	RAILWAY EXECUTIVES	ASSOCIATION OF RAILWAY SECURITY OWNERS	INTERSTATE COMMERCE COM.	WALKER D. HINES DIRECTOR GENERAL	BROTHERHOODS	VICTOR MORAWETZ	PAUL WARBURG
OWNERSHIP AND OPERATION	Private.	Private.	Private.	Private.	Government ownership. Operation by private corporation run by employees, which pays government a rental out of the receipts of operation.	Private.	Private
MERGERS	Federal incorporation with mergers allowed, subject to approval of Secretary of Transportation.		Mergers of existing companies may be made in the public interest.	Roads of each locality to be combined into regional systems, six to twelve in number.	Roads all to be operated by one private corporation, stock of which is to be held in trust for the exclusive benefit of the employees.	Railroads to be consolidated into ten or fifteen Federal corporations. Present securities to be refunded by 4% debentures and stocks.	Under Federal franchise, mergers may be made, subject to supervision of Federal regulating body.
REGULATION OF SECURITIES	Federal control exclusively.	Under supervision of Regional and Interstate Commission.	Federal regulation of the issuance of securities.			Debentures and stock to be issued only as authorized by Federal Railway Board.	By Federal regulating body.
CONTROL	A cabinet officer "Secretary of Transportation" to be appointed. Interstate Commerce Commission should be relieved of executive and administrative duties, except as to valuation and accounting, and act as quasi judicial body. Regional Commissions.	Federal regulation through Interstate Commerce Commission, as at present constituted, co-ordinating with six Regional Commissions—Co-ordination between State and Regional Commissions.	Better defined relationship between State and Federal control. A broadening of Federal control.	Five-year extension of Federal control. Modified private operation and control thereafter. Government representation on Boards of Directors.	No "Secretary of Transportation" continuation of powers of Interstate Commerce Commission. The directors shall be selected, one-third by non-appointed employees; one-third by appointed officers and employees; one-third by President.	Federal corporations to be under regulation of a Federal Railway Board headed by Cabinet Officer. Specified number of directors of Federal corporations to be appointed by Federal Railway Board. Regional boards and one central board of regulation.	Regional Board upon which State commissions might be represented with a reorganized Interstate Commerce Commission of 5 or 7, half judicial and half administrative in character at head
RATES AND RETURN ON CAPITAL	Regulation of rates by Federal government exclusively. Carriers may initiate rates which shall become effective unless disapproved by Secretary of Transportation. Statute shall specifically provide for adequate rates, which must reflect cost of wages and other expenses. Rates may, upon complaint be brought before I. C. C. for review with power to prescribe minimum rates.	A minimum rate of return, fixed by Act of Congress, through rates adjusted as occasion may demand. Interstate rates to be left in hands of State Commissions.	Revenues should be "adequate" and "reasonable." No statement as to any change in the method of rate procedure.	Government to ascertain and guarantee railroads a fixed fair return.	Under regulation of Interstate Commerce Commission. When the government's share of the distribution of profits exceeds 5% of the gross operating revenues, reductions in rates should be made to absorb the 5%.	To be regulated by Federal Railway Board through central and regional boards; local rates to be referred to regional boards, through rates to central board.	Rates to be determined by Federal regulating body. Railroads accepting plan to be guaranteed 4½% on Federal valuation.
DISTRIBUTION OF PROFITS		Earnings in excess of fixed reasonable return to be distributed among employees, railroads earning them, and for certain improvements not to be capitalized in rate making.		Profits above the specified fair return are to be moderately shared in by the railroads and the government, possibly also by labor.	Government guarantees return on bonds issued in exchange for existing capital. Any balance over this is to be divided between operating corporation and the government for the purpose of enabling the Interstate Commerce Commission to reduce rates. The operating company will disburse its share to the employees, in proportion to their annual wages.	Government to guarantee dividends of $2.50; any distribution in excess of $4 to be divided with government. Government to have option to buy stock at any time at $85 per share.	Any return on capital between 6% and 7% to be divided with government and possibly with labor. All over 7% to go to government.
FINANCING	Provisions to be made for funding by the United States of indebtedness of carriers to it growing out of Federal control.	A Federal corporation directed by the nine Interstate Commerce Commissioners and eight railroad men to finance purchase of equipment from the Railroad Administration, purchase of new equipment, and financing of the return of the roads to private control.		Comprehensive program of capital expenditure during five-year period; probably to be provided partly by government; partly by roads themselves where able to borrow.	All financing to be done by the government.	Debentures to be issued to an amount such that interest requires 40% of operating income. Balance of operating income to be capitalized at 6% in stock.	
JOINT USE OF TERMINALS, ETC.	Subject to direction of the Secretary of Transportation; also other similar matters.	To be arranged, also rerouting of freight, etc., by above Federal Corporation.					
WAGES	This and similar questions to be settled by officers and representation of individual employees affected, if possible, otherwise by a board under the Secretary of Transporation.	Regional Commissions to act as Boards of Conciliation. Appeal to Interstate Commission.			A committee of nine direcors of operating company empowered to make binding and final decisions in all wage disputes.		

Reinforced-Concrete Lift-Span Towers for Highway Bridge

BY F. H. FRANKLAND
Consulting Engineer, New York City

ECONOMIC studies for a reinforced-concrete highway bridge over the Osage River, near Jefferson City, Mo., on the main highway between Kansas City and St. Louis, showed that at the present prices for structural steel in place, reinforced-concrete towers for the lift span were not only about $4000 cheaper than structural steel towers, but the advantages from improved appearance and the use of more permanent materials were considerable. The difference in cost for reinforced-concrete towers, as against structural steel towers, above the roadway was found to be approximately $2000. Owing to the increased vertical reactions on the piers due to the use of the heavier concrete towers, it was found possible to reduce the width of the arch abutment piers, thereby saving an additional amount estimated at $2000.

The total length (810½ ft.) includes six barrel, open-spandrel arch spans, 92 ft. c. to c. of the piers; one steel deck-truss lift span, giving a clear horizontal opening of 85 ft., and a vertical clearance of 47 ft. above standard high water, and a series of continuous concrete deck girder spans at each end, each consisting of one 30-ft. span, two 20-ft. spans, and finished with an 8-ft. cantilever girder, which is buried in the approach fill. The pavement on the approach spans consists of a 2-in. concrete wearing surface, in which special aggregate is used, and on the lift span creosoted wood block on creosoted subplanking is provided. The lift span is operated by hand power, from a capstan at the center of the span actuating a worm reducing gear which is connected directly to the hoisting drum. The worm gear is completely incased in an oil-tight box, and runs in castor oil.



GENERAL ELEVATION AND DETAILS OF REINFORCED-CONCRETE TOWERS

The lift-span towers were designed to carry the load from the sheaves and also to take care of a 30-lb. wind stress. The sheave girder is designed for the sheave loads and wind stresses, and the other cross-girders for wind stresses only. In the upper portion of the tower the central 2-ft. portion of the column is assumed to carry all of the sheave load, the wind loads being divided between this 2-ft. portion and the two 9-in. portions. At the bottom of the tower all of the loads are assumed to be divided over the entire section of the column. Below the roadway surface the tower columns carry the deck loads in addition to the sheave loads and wind loads. The towers have been designed throughout with the minimum sections which it was found practicable to use and still retain ample clearances for the counterweight sheaves and the lifting girders on the movable span.

As there is a limited amount of money available for the construction of this bridge, the general architectural appearance of the towers is perhaps not quite as satisfactory as would have been the case if strict economy in design had not been enforced. However, by a judicious use of openings, as regards shape and spacing, and by slightly battering the outside faces of the towers, together with the use of a suitable cornice and molding, it is felt that a satisfactory æsthetic appearance has been obtained, while at the same time gaining the advantage of the use of permanent materials.

The structure was designed by the writer's firm, Waddell and Son, Inc., New York and Kansas City, consulting engineers for Cole and Osage Counties, Missouri.

The bridge has been designated as a Federal-aid project, and state aid has also been obtained by the counties interested. The engineers will supervise construction.

How to Make Isometric Working Drawings to Scale

BY GEORGE PAASWELL
Civil Engineer, New York City

ISOMETRIC drawings are usually sketch attempts to visualize a more or less complicated detail, and used merely to complement working drawings. There is no reason why an isometric drawing cannot itself be properly dimensioned and scaled and used as a working drawing, thereby replacing sundry plans and sketches. With this in view, at attempt has been made below to give a few formulas and then develop tables from them, so that the ordinary draftsman will have no difficulty in making his isometric drawing as exact as his working drawings.

Lines parallel to the isometric axes are, of course, shown correctly to scale; nonisometric lines are not shown to scale. The following are some simple theorems in what may be termed isometric trigonometry, the application of which should vastly simplify the plotting and dimensioning of nonisometric lines.

ISOMETRIC TRIGONOMETRY

It is assumed that the axes of the figure have been so chosen that all lines of importance lie in planes parallel to the principal planes of the figure. The following theorems apply solely to such lines. Thus in Fig. 1, the lines L, b and c lie in a plane parallel to one of the coördinate planes adopted in space, and b and c are parallel to two of the coördinate axes. Fig. 2 shows the

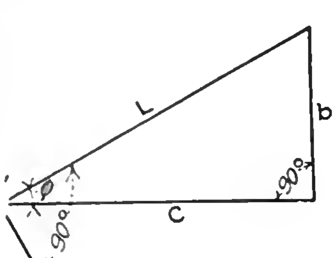


FIG. 1

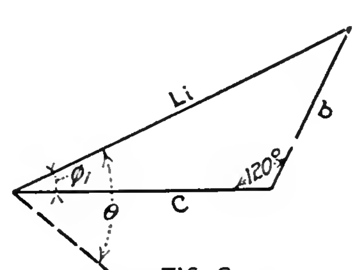

FIG. 2

FIGS. 1 AND 2. DIAGRAMS SHOW FUNDAMENTAL RELATIONS

same configuration in an isometric drawing. The lines b and c remain, of course, of the same length. The line L which made an angle ϕ with c, now makes an angle ϕ_i with c. The lines b and c which formerly were at right angles to each other, now make an angle of 120°. In Fig. 1, $\tan \phi = b/c$; in Fig. 2, by the law of sines, $b/c = \sin \phi_i / \sin (180° - 120° - \phi_i)$, whence

$$\phi_i = \cot^{-1}\left(\frac{1 + 2 \cot\phi}{\sqrt{3}}\right) \qquad (1)$$

If a line be drawn at right angles to L and in the same plane, it may be divided into two angles, ϕ and $90° - \phi$. The angle $90° - \phi$ becomes, in the isometric plane, from (1), above,

$$\cot^{-1} \frac{1 + 2 \cot (90° - \phi)}{\sqrt{3}} = \cot^{-1} \frac{1 + 2 \tan\phi}{\sqrt{3}}$$

and the original right angle now becomes

$$\cot^{-1}\left(\frac{1 + 2 \cot\phi}{\sqrt{3}}\right) + \cot^{-1}\left(\frac{1 + 2 \tan\phi}{\sqrt{3}}\right) \qquad (2)$$

Or, from $\theta = A + B$ and the trigonometrical formula

$$\cot \theta = \frac{\cot A \cot B - 1}{\cot A + \cot B}$$

by substituting the two angles in (2) for A and B, the value of $\cot \theta$ reduces to $1/\sqrt{3}$, therefore $\theta = 60°$, and a right angle in space becomes an angle of 60° in the isometric plane. Hence angles complementary in space add up to 60° in the isometric plane.

From (1) with ϕ_i given, $\phi = \cot^{-1}\left(\frac{\sqrt{3} \cot \phi_i - 1}{2}\right)$ (3)

Table I gives values of ϕ_i from ϕ, and can also be used conversely with sufficient accuracy.

TABLE I—VALUES OF ANGLES ϕ AND ϕ_i

ϕ	ϕ_i	ϕ	ϕ_i	ϕ	ϕ_i	ϕ	ϕ_i	ϕ	ϕ_i
0	0	10	8	20	15	30	21	40	27
1	1	11	9	21	16	31	22	41	28
2	2	12	9	22	16	32	22	42	28
3	3	13	10	23	17	33	23	43	29
4	3	14	11	24	18	34	24	44	29
5	4	15	12	25	18	35	24	45	30
6	5	16	12	26	19	36	25	..	.
7	6	17	13	27	19	37	25	..	
8	7	18	14	28	20	38	26	..	..
9	7	19	14	29	21	39	27	..	.

Again, to find relation between lengths L and L_i.
In Fig. 1, $L^2 = b^2 + c^2$
In Fig. 2, $L^2_i = b^2 + c^2 - 2bc \cos 120° = b^2 + c^2 + bc$
$= L^2 + bc$
From Fig. 1, $b = L \sin \phi$ and $c = L \cos \phi$, and $bc = L^2 \sin \phi \cos \phi$ whence $L_i = L\sqrt{1 + \sin \phi \cos \phi} = kL$,
where $k^2 = 1 + \sin \phi \cos \phi$
and conversely, $L = KL_i$, where $K = 1/k$.

Table II gives values for k and K.

To obtain the length of a line not lying in these so-called principal planes—i.e. planes parallel to the

TABLE II. VALUES OF COEFFICIENTS k AND K

ϕ	k	K	ϕ	k	K	ϕ	k	K
0	1.00	1.00	16	1.13	0.89	32	1.21	0.83
1	1.01	0.99	17	1.13	0.88	33	1.21	0.83
2	1.02	0.98	18	1.14	0.88	34	1.21	0.83

7	1.06	0.94	23	1.17	0.86	39	1.22	0.82
8	1.07	0.93	24	1.17	0.85	40	1.22	0.82
9	1.08	0.93	25	1.18	0.85	41	1.22	0.82
10	1.09	0.92	26	1.18	0.85	42	1.22	0.82
11	1.09	0.91	27	1.19	0.84	43	1.22	0.82
12	1.10	0.91	28	1.19	0.84	44	1.23	0.82
13	1.10	0.90	29	1.20	0.84	45	1.23	0.82
14	1.11	0.90	30	1.20	0.84		....	....
15	1.12	0.89	31	1.20	0.83		....	....

adopted planes of reference—it is too cumbersome and therefore of little practical value to establish general formulas. If the coördinates of the two terminals of the line are obtained, then its length is easily found from the expression

$$\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}$$

where $x_1y_1z_1$ and $x_2y_2z_2$ are the terminal coördinates.

In usual practice, however, it is possible to locate the planes of reference so that all the lines of interest lie in planes parallel to these reference planes. It is also usual to record on the drawing the true dimensions and angles, not the corresponding isometric values.

If a curve is given in space, lying in a plane parallel

to a reference plane, draw vectors to several points on the curves from the origin in the plane. The angles which these vectors make with the reference axis, and the lengths of these vectors, when properly reduced by the given tables, serve to locate the given curve in the isometric plane.

In the accompanying drawing, Fig. 3, is shown an isometric detail at the intersection of an abutment and retaining wall. The line of intersection of the two faces is taken as the vertical axis. The datum line 100 along the face of the retaining wall is taken as the x axis. The y axis is then drawn at the same elevation.

The angle between the abutment and the retainingwall is 70° or 20° with the y axis; from the tables the corresponding angle in the isometric plant is 15° and a line making this angle with the y axis in the isometric plane is drawn, giving the datum 100 along the face of the abutment.

All true dimensions parallel to this line are then multiplied by the coefficient k for 20°, 1.15 from Table II, to get the lengths in isometric projection. Similarly, all dimensions at right angles to the face of the abutment are multiplied by the same coefficient.

It is easy to see how, in making an isometric of a skew portal or of hips and valleys, etc., scale drawings can be prepared to give all necessary information properly dimensioned.

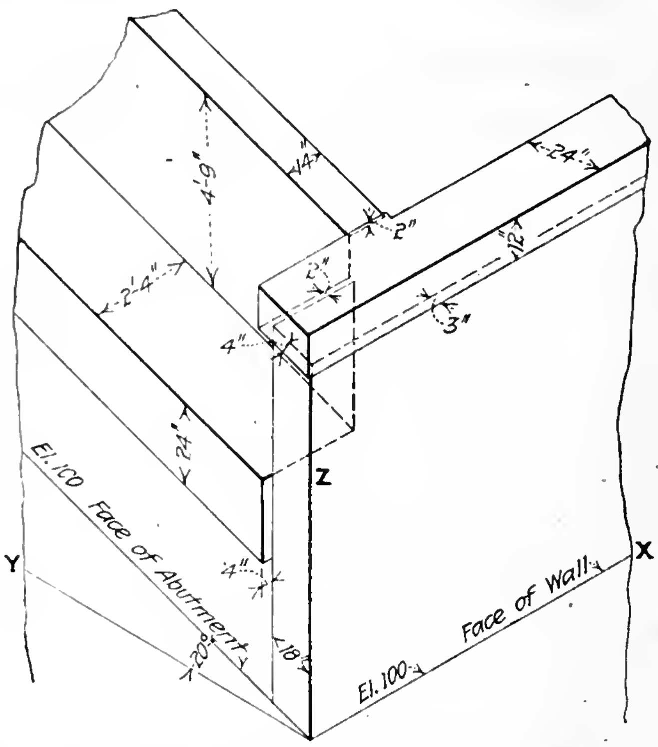

FIG. 3. INTERSECTION OF RETAINING WALL AND ABUTMENT

High Rate of Filtration Feasible for Detroit Water-Supply

Experiments Warrant Recommendation for Rate of 175,000,000 Gallons per Acre—Estimates for 300,000,000-Gallon Plant

RECOMMENDATIONS for a mechanical water-filtration plant for Detroit, with a nominal capacity of 300,000,000 gal. a day, operating at the unusually high rate of 175,000,000 gal. an acre after a retention of 13 min. in the mixing chambers and two hours in coagulation basins, have been made by R. Winthrop Pratt, consulting engineer, Cleveland, Ohio, in a report to the water commissioners. The estimated cost of the plant is $5,800,000. Under the "present rate policy," Mr. Pratt says, filtration and extra pumping "would cost domestic consumers 6c. per 1000 cu.ft., or less than 1c. a day per family." The high rate of treatment and low unit cost of filtered water mentioned further on are made possible by a relatively low turbidity and other favorable local conditions. The use of filter sand having an effective size of about 0.5 mm. will result in a large saving of waste water.

To obtain data that would be a safe guide in adapting mechanical filtration to Detroit conditions, a 200,000-gal. experimental plant was operated for a full year, ending Sept. 30, 1918. A description of this plant and a summary of the operating results are given in the report. It may be noted also that pains were taken to write a report that should be readily understood by the citizens and voters of Detroit; also, during the tests filtered water was piped to a plate-glass tank for public inspection, and visitors were encouraged to carry away filtered water. The booth covering the tank also contained a model of a filter and samples of turbid water.

The plant is designed for a regular working capacity of 288,000,000 gal. (72 filter units at 4,000,000 gal. each) which may be increased temporarily to 300,000,000 gal. Provision is made for enlargement to a nominal capacity of 450,000,000 gal. a day. The velocity in the mixing chambers would be 1.4 ft. per second and in the coagulation basins 3 ft. per minute. A 36,000,000-gal. clear-water reservoir is provided for.

The cost per 1,000,000 gal. of treating 250,000,000 gal. a day, including low-lift pumping, is estimated at $7.91, divided as follows: Low-lift pumping, $1.60; coagulation and filtration, including waste water, $2.06; capital charges, at 6.505%, $4.22.

During the experimental year the average turbidity of the raw water was 30 p.p.m. On 205 days of the year the turbidity exceeded 20 p.p.m. and on 39 days it was over 50 p.p.m. The maximum turbidity for the year was 490 p.p.m., on Apr. 12.

The tests indicated that alum would be cheaper and less troublesome than iron and sulphate of lime for coagulant.

Typhoid statistics from the Detroit Health Department, quoted in Mr. Pratt's report, show an average death rate of 13.47 per 100,000 for the past six years, ranging from 25.70 for 1913 to 7.45 for 1918. With the exception of 1913, the highest rate was 12.9 in 1917.

The investigations on which Mr. Pratt's report is based were in immediate charge of F. H. Stephenson, principal assistant engineer.

Engineers and Lawyers on a Par

County highway engineers in Missouri are considered by certain legislators to be worth at least as much as lawyers. In Senate Bill No. 427, under the heading "Compensation" the following clause appears: "The county highway engineer shall receive the same compensation as is now provided by law for the prosecuting attorneys in the various counties of this state, and his salary shall be computed and paid on the same basis as now provided by law in relation to the office of prosecuting attorney."

Segment Blocks Have Advantages on Larger-Size Drains

Lightness, Ease of Handling, and Small Breakage Are a Few of the Desirable Characteristics—Trouble with Unstable Soils

By D. L. Yarnell
Senior Drainage Engineer, Bureau of Public Roads and Rural Engineering

Although segment blocks have been used in the construction of sewers for some time, their entrance into the field of tile drainage has been only within recent years. Segment blocks are somewhat similar to building blocks in that they are hollow, with interior walls so arranged as to obtain the maximum strength. They are made of clay, vitrified and salt-glazed, with tongue-and-grooved side joints and with either square ends or ship-lap end joints. In sewer construction the aim is to have a water-tight conduit, while in drainage work the joints should be only closely butted together in order to permit water to enter the drains. Thus in sewer construction all joints of segment blocks are cemented.

In drainage work, usually, none of the joints is cemented. However, in main drains of large diameter the necessity of permitting the water to enter the joints is not so important, since the submains and laterals deliver the water to the main, and cementing might be desirable, but, to make the contractor cement all joints to give additional strength would increase the cost of constructing segment-block drains. Manufacturers of segment-block conduits in many cases have underbid manufacturers of large concrete tile.

Comparative Cost of Segment-Block and Solid-Tile Drains

Although segment-block drains of 30 inches in diameter are made, the smallest size used in drainage work, so far as the writer knows, is 36 in. The largest segment-block drain laid, to the writer's knowledge, is 52 in. in diameter, while the largest concrete tile manufactured is 50 inches.

It is interesting to compare the costs of the solid tile with segment blocks. The following table gives comparative costs obtained during July, 1917:

PRICES PER LIN.FT. F. O. B. FACTORY

Size In.	Segment Block (No. 2 Grade)	Cement Title	Size, In.	Segment Block (No. 2 Grade)	Cement Title
30	$1.08	$1.175	40	.....	$2.040
32	.....	1.275	42	$1.62	2.250
33	1.19	......	44	.....	2.475
34	.....	1.425	45	1.74	...
36	1.30	1.650	48	.....	2.940
38	.....	1.875	50	.....	3.200
39	1.51	......			

On the Hamilton County, Iowa, Drain No. 4, the bids received for 3750 ft. of 39-in. tile delivered along the line of drain were as follows: Solid tile, $11,452; segment-block, $8851 and $8993.

The complete bids received on this drain for labor, and furnishing and hauling tile, were as follows: Using solid tile, $15,500; using segment-block, $12,800.

From these data it may be inferred that the cost of installing segment blocks is about the same as for solid tile; however, that may not be true under all conditions. It should be noted that this drain was laid in the bottom of an old ditch, the average cut being about six feet.

On the Webster, Hamilton and Boone Counties, Iowa, Joint Drain No. 1-192-210, bids on the following size of tile delivered along line of drain were received: 1460 ft. of 52-in., 850 ft. of 48-in., 600 ft. of 42-in., and 6250 ft. of 39-in. A segment block manufacturer was the lowest bidder and was awarded the contract at a cost of $23,895.

Difficulties with Segment Block Drains

In construction the contractor lays the invert block to grade. The other blocks are then added, and the space around the tile is filled with earth. The last block on top, the key block, is usually slipped in place by hand, few drainage contractors using the arch form recommended by segment block manufacturers. The arch form consists of an adjustable semi-circular form mounted on a V-shaped frame. This form is designed to facilitate the laying of the upper blocks of the drain, being pulled ahead in the drain as the construction progresses. Of course, all joints on the drain are staggered.

If either tile or segment block drains are laid in trenches constructed in stiff soil where sheeting is unnecessary, excellent work can be done. The writer has seen segment block drains laid so true that the most exacting person could not find fault. However, in unstable soil, where sheeting is necessary, some trouble may be experienced after the blocks are laid and before the trench is back-filled. So far as the writer has observed, no failures have occurred after the trench has been back-filled. When the soils are unstable the lateral pressures in some cases are so great, before the trench is filled, as to cause the drain to collapse. The resistance of the drain to lateral pressure is increased by back-filling. Where sheeting is necessary, the back-filling must sometimes be done before the sheeting can be removed, and the contractor must leave it in. Resistance of the drain to lateral pressure can also be increased by cementing the joints. By leaving an occasional joint between the ends of blocks uncemented, water can be admitted to the drain. In back-filling the drain, great care should be exercised to see that the earth is carefully tamped between the drain and the side of the trench, until it is well above the springing line. Even in the best of material the trench should be back-filled as rapidly as possible after the blocks are placed.

The limit to the size of clay drain tile (due to the limits in size of machines used in manufacturing), is approximately 30 in., and for concrete tile, due to handling, about 50 in. Thus the segment block, on account of easy manufacture and handling, fills an important need for the larger sizes of drains. With large tile, where sheeting is necessary, the bracing must be far apart to admit the large tile. With segment blocks this trouble is eliminated.

The comparative weights of segment blocks and concrete tile are given in the following table:

	—Segment Block—		—Concrete Tile—	
Size	Weight per Block	Weight per Lin.Ft. of Drain	Weight for Each Tile	Weight per Lin.Ft. of Drain
In.	Lb.	Lb.	Lb.	Lb.
30	54	270	750	300
36	54	324	1,100	440
42	58	406	1,800	600
48	72	504	2,355	785

Thus it can be seen that the lightness of segment blocks constitutes a great factor in the shipping and

hauling of material. The segment block is compact and light, compared with solid tile. The loss due to breakage is not so great, since, if a block is broken the loss is slight, whereas if a concrete tile is broken, one entire length is gone. With a 42-in. drain the loss due to breakage of one segment block is 12c., as compared with $2.25 for a broken concrete tile. In spite of the difficulties of construction in unstable soil, there is no doubt that the use of segment blocks for tile drains will increase, due to the lightness and convenience of handling and the advantages in laying.

The above investigation was made and the report prepared under the direction of S. H. McCrory, chief of drainage investigation, Bureau of Public Roads and Rural Engineering.

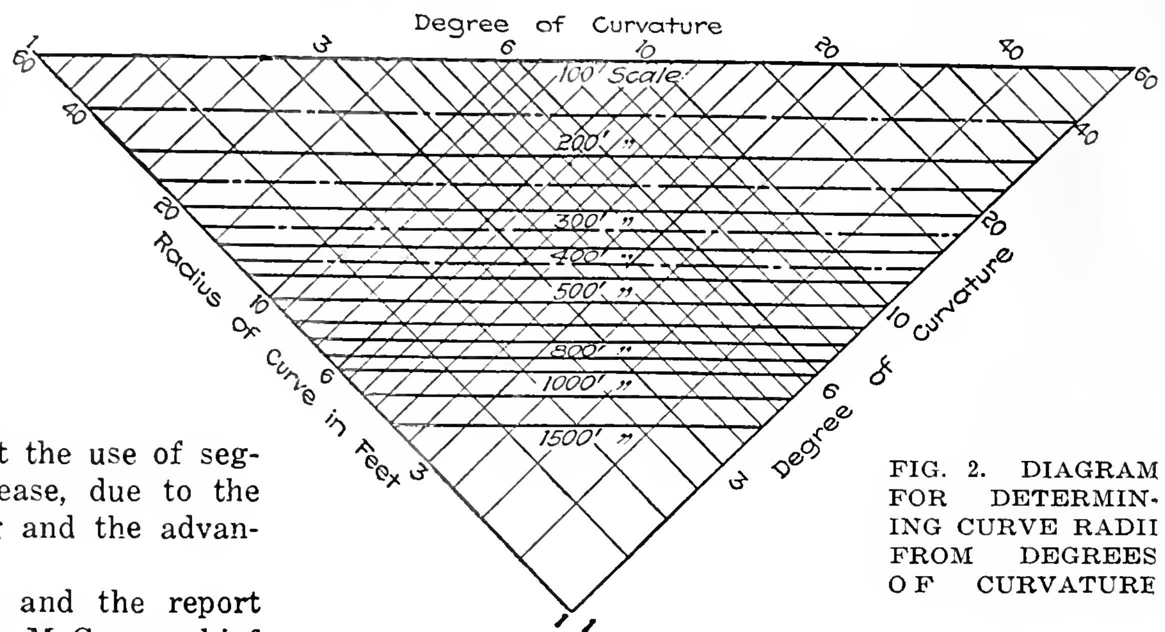

FIG. 2. DIAGRAM FOR DETERMINING CURVE RADII FROM DEGREES OF CURVATURE

Assembled Curves and Radii Diagram Aid in Railroad Drafting

By Dwight Gerber
Pittsburgh Terminal R.R. and Coal Co., Pittsburgh

Two diagrams, illustrated here, have been found useful by the writer in handling railway curve work in the drafting room.

Fig. 1 shows a plan for assembling all curves ordinarily used—with a short tangent and the tangent point indicated on each—on one sheet of tracing cloth. The curves are arranged to facilitate the choice of a particular curve through intersecting predetermined points.

A little use of such a sheet as this will demonstrate the ease with which a choice of curves can be made, as compared with the usual method of sorting curves on a fit-and-try method. It will be self-evident how to use the curves drawn to the scale of 100 ft. to the inch in connection with other scales. Even though none of the scales as drawn will fit exactly, it is very easy to make a close approximation by interpolation of what curvature will fit.

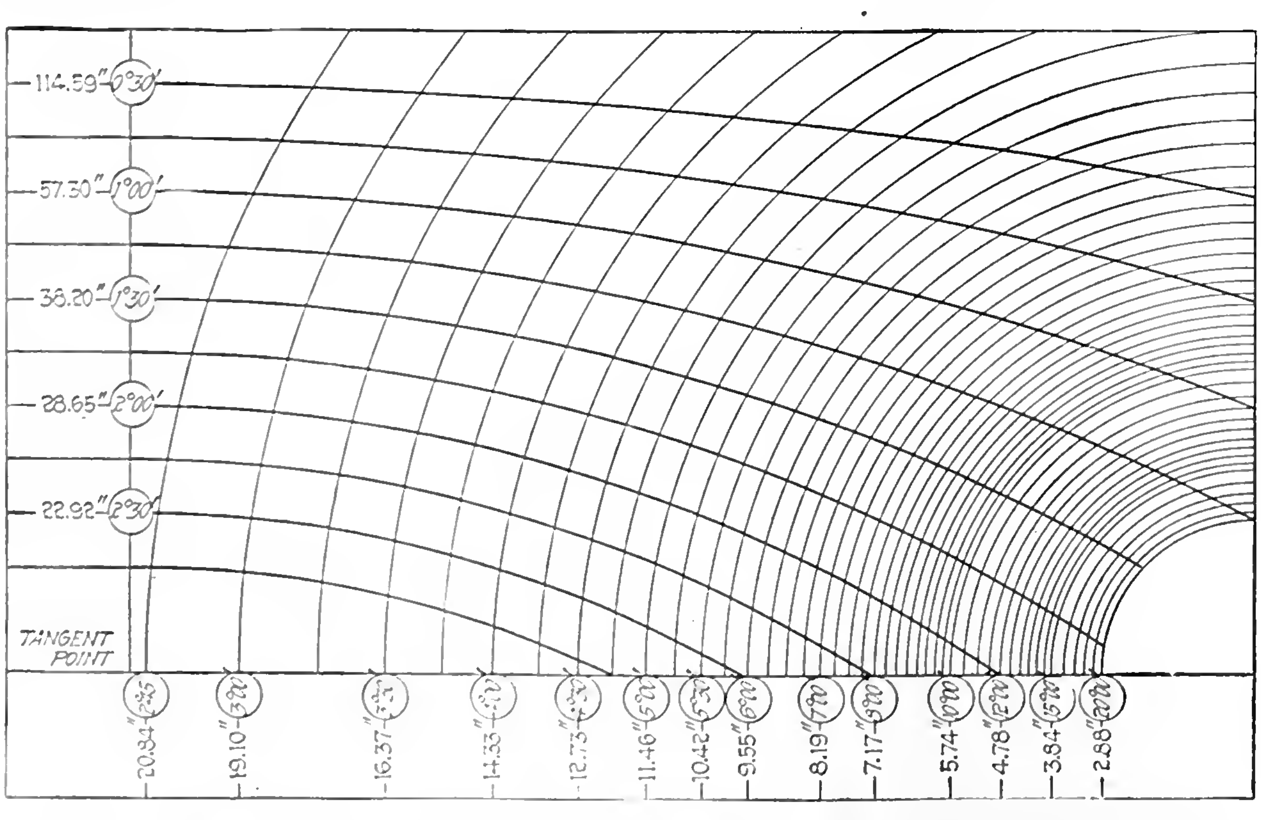

FIG. 1. PLAN (NOT TO SCALE) FOR LAYING OUT ALL CURVES WITH SHORT TANGENTS ON ONE SHEET OF TRACING CLOTH

A second sheet will be found very convenient in laying in a compound curve.

Fig. 2 shows a line chart which will serve as a ready reference to check the calculations of curve radii, which are usually made mentally and are often in error. The chart is laid out on logarithmic cross-section paper. The horizontal lines indicate the degree of curvature, the vertical lines the radii of curves, and the diagonal lines the various scales as marked.

As an example of the use of the chart, to find the radius of a 2.6° curve on a scale of 350 ft. to the inch, follow the horizontal line designating 2.6° to the 350 diagonal, then read down 62.9 feet on the vertical line.

Heavy Construction Marks New Pacific Coast Railway

The line of the San Diego & Arizona Ry., now being built across Laguna Range in California to connect El Centro with San Diego, traverses some remarkably rugged country that called for heavy construction. A map and profile of the line appeared in *Engineering News-Record* of Oct. 22, 1918, p. 365. Through Carriso Pass the grade has been kept down to 1.4%, because the cost of reducing grade later would be prohibitive. Elsewhere the grades run up to 2.2%, with 10° maximum curves. In the 12-mile section of the railroad that lies between Jacumba and Carriso Gorge there are 17 tunnels. Of these, two are about 2500 ft. long, one is about 1200 ft., and the remaining 14 are between 180 and 900 ft. The formation was loose, so that 75% of the total length required timbering. There remains to be completed a length of about 11 miles of the mountain division, and crews are now working on both ends of the gap. It is expected that the line will be ready for operation some time during the coming summer.

American Engineers Kidnaped by Chinese Bandits

Chief Engineer of American Company Building Chinese Railways Was Kept in Captivity for Nearly Two Months

SOME few outposts of civilization remain where the engineer is still pioneering, where the adventures so common in the engineering of a half century ago and between the covers of the modern novel may be had for the asking. One of these places is China. Over there, nearly a year ago, a little band of engineers, almost totally neglected in the clamor and publicity of the great war, went through an experience that ought to make good reading for those boys who wonder what they are going to do for excitement now that the war is over. One of the men, a prominent American railway engineer, George A. Kyle, has just come home from the Orient, and, on urging, has been persuaded to tell the story of his misadventure.

Mr. Kyle was the engineer selected by the American International Corporation to take charge of the construction of the railways in China for which the American Siems-Carey Railway & Canal Co. took a contract a few years ago. He left this country in November, 1916, and from the time he reached China until last spring he was engaged in the supervision of the several lines the company had under way. One of these was projected to extend from the main line of the Pekin-Hankow railroad due west a distance of about 900 miles into the Szechuan valley.

In March of last year American newspapers carried a brief paragraph to the effect that two American engineers had been taken into captivity by bandits operating in one of the eastern Chinese provinces. There was plenty of other excitement in the world just then, and the item did not reach much prominence, nor were the men heard of again until some time in May, when it was announced that they had been freed. Mr. Kyle and E. J. Pursell, a construction man with the company, were the two white men who were captured.

They had started Mar. 2 with a staff of Chinese engineers and servants, about forty in all, on a trip to the western end of the Szechuan line, where several engineering parties were working. They were accompanied by a police guard from Pekin and about 25 so-called soldiers assigned to them by the Government, because reports from time to time came into headquarters indicating that bandits were operating in the districts through which they had to pass. The men, however, were not particularly concerned regarding the dangers which they might encounter.

The Capture

After they had gotten some forty miles out of the town of Yen Shiang, which was the last headquarters of the railway forces, their caravan, made up of 18 two-wheel carts drawn by mules, was attacked without warning by a gang of bandits lying in ambush some hundreds of yards off the traveled road. The first notice was a fusillade of gunshots, on hearing which Mr. Kyle and Mr. Pursell, together with some of the loyal servants and two high-class Chinese who were with them, made for a nearby Chinese village behind its walled inclosure or compound. When they got there they found the soldier guard missing, nor were they heard from again except for some desultory firing on the bandits after the Americans had been captured.

Within the compound the small remaining party began a vigorous defense, but they were soon convinced that they were bound to be overcome by weight of numbers alone, to say nothing of force of arms, for the robbers were apparently well armed with modern rifles. Besides the servants, there was an engineer named T. C. Hu, a graduate of Cornell University, who was the Government representative for the inspection of the work which they were about to visit, and an American citizen of Chinese birth named Wu, who acted as interpreter. These four, the only ones armed in the party, threw away their revolvers and made signs of surrender, whereupon the bandit crew entered the compound and, to the surprise of the Americans, opened fire with revolvers at about 15-ft. distance. Thanks to poor marksmanship, there was no damage except a cut in the shoulder of Mr. Kyle's coat. The loyal Chinese managed to persuade the bandits of the completeness of the surrender, however, and they immediately took possession of the party and all their belongings, which included about $14,000 in silver, pay being taken out to the engineering party.

Lives in Constant Danger

In no recent time has any white man been taken captive by the Chinese bandits who roam the country apparently at will, and neither Kyle nor Pursell was very much concerned about his personal future once the gang had appropriated all the property of the party. They were, therefore, much surprised when the bandit chief announced that the two white men and Wu, the interpreter, were captives, though for what reason he did not then choose to tell. He straightway started the three men on a rapid march into the mountains, a strenuous trip taking about eight days. During all this time they were fairly well cared for as to food, but they were constantly being threatened by the members of the band and apparently in constant danger of being the victims of sudden temper on the part of some individual. After they had gotten well back into the wilds, it then being Mar. 12, the bandit chief announced that they were to be held for ransom in the following amount: Two hundred rifles with 200,000 rounds of ammunition and 200 automatic revolvers with 100,000 rounds of ammunition. The bandits themselves were well armed at the time and were apparently quite competent to take care of the modern firearms which they carried, though they were anything but good shots. It was agreed by the bandit chief that a message to this effect was to be delivered by Pursell to a Roman Catholic priest, named but not identified, and that the material was to be delivered by Mar. 25 on the penalty of the deaths of Kyle and Wu, who were to be held. For some reason the scheme fell through, and the march continued.

In the meantime Hu, the Chinese engineer, had escaped from the compound and back to the telegraph office where he notified the American legation, the Siems-Carey headquarters and the Chinese Government of the state of affairs. Immediately all kinds of machinery were set on foot to effect a rescue. It was very difficult, however, to know what move to make. The country where the bandits roam is very wild and absolutely without Governmental control, except that of the heads of the province who in a way are kings unto themselves and not much concerned about the possible

anger of the United States Government. Headquarters at Peking and all the Americans hesitated to send troops because of the fear of injury or death to the captives.

After the ammunition proposal fell through, for some reason unknown to the captives, they were taken every night on marches into country strange to all of them, even the native. They walked from 10 to 30 miles every night, sleeping in various towns or under cover in the daytime. As far as they were able to find out afterward, they were walking in circles, and were never more than 100 miles from the compound where they were captured. The only daytime walk that they made resulted in an incident which Mr. Kyle thinks was planned in advance in order to intimidate the captives. One afternoon, about four o'clock, they started out on a short march and went by a little village. Apparently all the villagers were gathered outside the compound to look at the procession, and one of the native men was summoned by a wave of the hand to come close by. He got within a short distance, when he was killed by a rifle shot by one of the bandits who then rushed the village and killed twenty-two of the villagers.

While this was possibly the ending or the middle of a feud between the bandits and the villagers, it is Mr. Kyle's opinion that it was "staged" so that they could realize that the men were dangerous and desperate characters. Immediately thereafter the chief of the band told Mr. Kyle that he must not have soldiers sent after him or the same sort of thing might happen. He did allow him, however, to send back messengers, who, by some unknown means, got Kyle's notes to Mr. Hitchcock, the representative of the railway company; the latter had by that time established himself at Yen Shiang. As a result of some of these messages, a little canned food was sent to the captives occasionally, but for the most part they had to live on what the natives could produce and what the bandits took with them. The bandits were always fairly well treated wherever they went, probably because they were known for the desperate character they undoubtedly won, though the Americans often thought that the gang was made up of a number of ostensibly peaceable farmers and villagers who took up banditing as a side line.

Attempt at Rescue

On Mar. 25, without warning that the Americans heard of, 500 Chinese soldiers crossed the path of the bandits and their captives and began an attack. A rearguard action was forced by the bandits, and the three captives were hurried off as fast as possible toward the mountains. They got to the top of the highest peak of the country and were starting to go across into another district when the bandits found they were surrounded by the soldiers, and the three captives, with four guards, lay flat on a hill while the heavy fighting was going on all around them. Here, the three thought, was an opportune time to escape, and all started to run. Kyle became separated from Pursell and Wu, who were guarded by one man only. They finally bribed this man to let them go, offering him a job as servant, which, curiously enough, he accepted. They escaped to the soldiers after being in captivity 22 days. Kyle's guards, however, stuck close by him through the fight.

Following this running battle, which lasted almost 24 hours, the bandit group, which comprised 85 to 100 men at first, was divided into small bands, one of which, consisting of seven men and the bandit chief, took Kyle with them into the mountains. They had a hard time escaping from the soldiers, but managed to break through after several attempts to get by pickets. Kyle might have escaped once when he was running along level ground and came to a deep vertical pitch over which all the men scrambled before him. Bullets were whizzing all around him, however, and he decided it was safer to follow his bandit captors down into the gully, protected from rifle fire, than to stay on top, possibly to be wounded or killed by the soldiers before they knew who or where he was.

When the bandits captured Kyle they had in their possession 17 native Chinese prisoners, whom they were holding for a ransom of $20,000. During the battle with the soldiers these prisoners escaped, much to the chagrin and anger of the bandits. Thereafter they were particularly careful of Kyle, because he was their only source of revenue. He never did find out, though, for just what ransom or reason they were holding him, although in certain conversations with Wu, before the latter escaped, the bandit leader intimated that all he wanted was enough arms and ammunition to set up as a soldier chief. Evidently, in that country political advantage is gained mainly by force of arms. At any rate, after Wu got away Mr. Kyle had no means of communication with his captors except by signs, and was ignorant of their intentions or of the progress of any negotiations for his release.

Final Period and Release

The night after the battle Mr. Kyle and his seven captors walked about 25 miles, out onto the Hunan plain. From that day, Mar. 25, they began a vagrant wandering at night, putting up in the daytime in villages where their hosts were very evidently in league with the band. At one time they crossed the railroad at a place which Kyle decided afterward must have been not more than 10 miles from Yen Shiang, where Mr. Hitchcock was conducting a campaign to reach him. Kyle managed to get occasional word via the underground messenger system to Hitchcock, but at no time did Hitchcock or any of the other Americans know just where he was. All during this time the seven men treated Kyle pretty well, though he had not had a bath for thirty or forty days and no change of clothing. The food was enough to keep him alive, although it was anything but good. Many times during the period from Apr. 1 to Apr. 12, when they were around railroads, he saw and heard trains going along, but could not get in touch with them.

On Apr. 21, however, he received in a letter from a native Roman Catholic priest the first real message from his friends. It was quite vague, but intimated that relief was assured. On Apr. 23 the party moved to a larger compound, where a Chinese Roman Catholic priest met him and told him that in two or three days he would be released. From then until Apr. 25 he was treated royally. On the latter day a local celebrity came along and took him, with the seven bandits, to Wu Yiang, where there were representatives of General Chang, one of the strong Chinese leaders. By the time they reached Wu Yiang a group of 3000 natives was marching alongside of the party, and the entry into the town was made with considerable ceremony. There Mr. Kyle found waiting some of his friends and, what he quite as much appreciated, his Chinese "boy" with a

change of clothes, and the monopoly for the day of a local bath house. It turned out that General Chang, knowing the ambition of the bandit leader, had sent the priest out to dicker, with the promise, in return for Kyle's life, of immunity from punishment and a captaincy in the Governor's bodyguard, together with positions as soldiers for the seven remaining men. The bandits agreed to this and, so far as Kyle knows, the agreement has been kept. He was in captivity 52 days.

Mr. Kyle thinks he never was in danger of his life after the first two men had escaped, but before that the very size of the gang made anything possible. The leader seemed to be pretty decent sort of pirate, who played fair and realized the value of the captives. The gunmen themselves, though, were blithe spirits who amused themselves by sticking a gun in a white man's ribs, and playing with the trigger. It was always about an even chance that one of them would consider pulling the trigger the final word in humor.

Relieving Arches in Subway Distribute Stress to Piers

Engineer's Special Design Meets Difficult Loading Conditions Imposed by Architect's Design—Groined Arches Used in Street Subway Under a Park

ARCHED sidewalk spans seated on the haunches of the roadway span in order to insure the desired distribution of stress constitute the distinctive feature of design in a three-span subway carrying a street under the grounds of the Iowa state capitol in Des Moines. The spans are groined arches with widely spaced piers instead of continuous bents for the intermediate supports. In the sidewalk spans these arches form a false roof concealing the structural or load-carrying arches. In carrying out the extension of the grounds or park it was necessary to extend a plateau south of the capitol and across Court Ave. to the crest of a bluff. At the same time it was desirable to avoid having the park intersected by a street, especially as Court Ave is a heavy-traffic thoroughfare forming one of the main routes between the city and the district beyond the capitol. The plan adopted, therefore, was to maintain the normal high level on the new fill for the park extension and to lower the grade of the street, carrying it under the park by a concrete subway.

SUBWAY UNDER IOWA CAPITOL GROUNDS HAS GROINED ROOF

From 4 ft. to 6 ft. of fill covers the structure, this depth being sufficient to allow planting of shrubbery. Tile drains are laid along the arches, leading to vertical drains in the piers. These piers are about 9 ft. square, and are spaced 38 ft. on centers longitudinally.

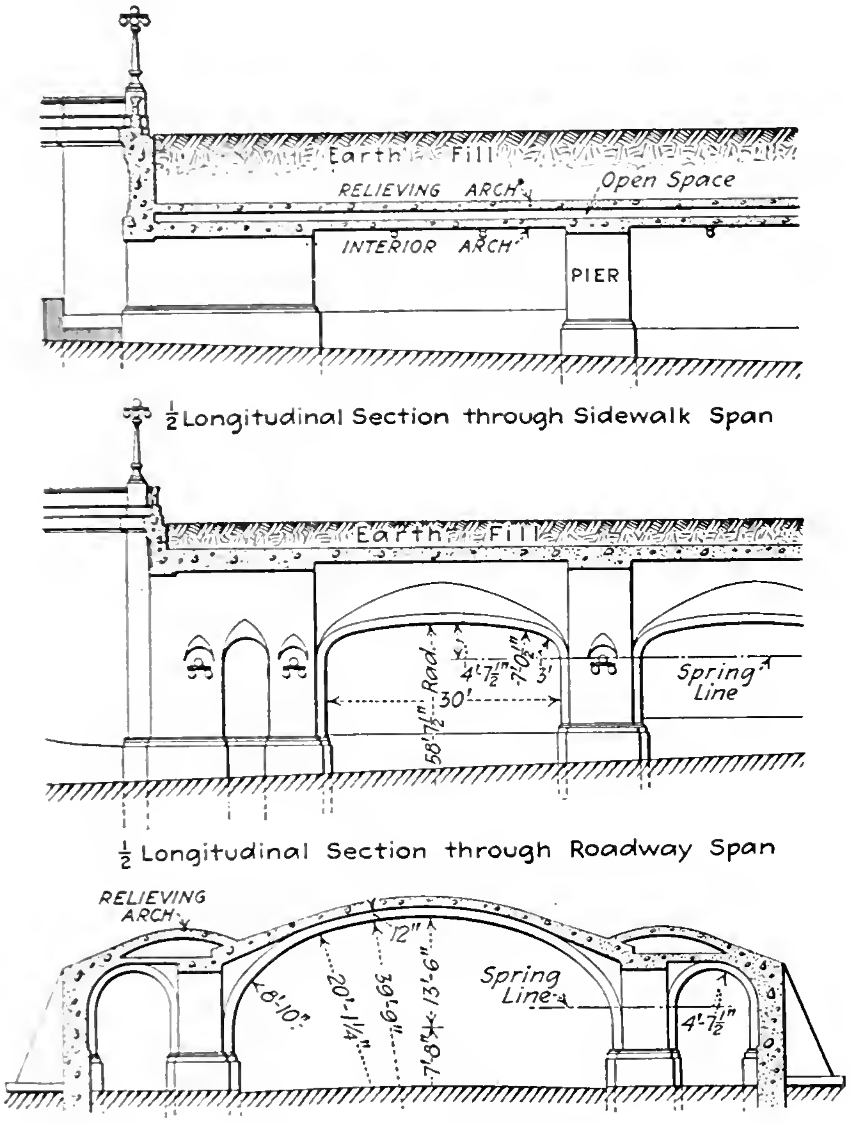
The visible or apparent span is 48 ft. clear for the central arch and 9½ ft. for the sidewalk arches. As the park surface and the crown of the arch are horizontal, while the street has a grade of four per cent., the height is different at the two ends, giving a different appearance to the portals. Thus, at the upper portal the height is 21 ft. 2 in. for the central arch and 13 ft. for the side arches, while at the lower portal these heights are 26 ft. and 19 ft., respectively. The length between the portals is 316 feet.

Architectural design of massive and monumental character is employed, and the bridge is flanked by long and high retaining walls on the street lines to retain the fill. On one side the wall has a curved return, with a winding stairway carried around its face. As it was intended that Court Ave. should have a street-car line, this stairway would accommodate visitors and employees. Reinforced concrete is used throughout, except that the portals have a decorative facing of Bedford stone and ornamental parapets of the same material. Electrical fixtures of bronze will be placed when the price of metal is lower.

Engineering conditions of the design were dictated largely by the architectural requirements, as follows:

The great difference in length between the roadway span of 49 ft. and the two sidewalk spans of 9 ft. 3 in., together with the prescribed outlines for clearance and æsthetic purposes, introduced a peculiar problem. It became apparent at once that resort must be had to some special expedient, in order to confine the line of pressures within the piers located along the curb line. Many schemes were tried and 14 different arch combinations were investigated. The adopted design consists of a relieving arch on either side, supported at one end on the haunch of the roadway arch and spanning over the sidewalk arch to the abutment. The visible sidewalk span is thus only a false arch.

The thrust of the relieving arch is introduced at such a point in the roadway arch that the resultant



SECTIONS SHOW DETAILS OF SUBWAY WITH GROINED-ARCH ROOF

of the two and the pier load fall within the prescribed outline of the pier. General reinforcement in the arches was introduced for its toughening effect, to prevent localization of any shrinkage, temperature or settlement strains in unsightly cracks.

The retaining walls and arch abutments are designed of the gravity, reinforced-cantilever or reinforced-counterfort type, as the interest of economy indicated for the several heights. It was thought that the curved plan of some of the walls offered opportunity for economy by taking advantage of the fact that such a wall, considered as a whole, has a greater stability, proportionately, than has any unit of its length. This was found to involve an analysis far more scientific in character than is warranted by any available data on earth pressure and foundation reactions. The curved walls, therefore, were designed on the same basis as the straight walls.

The live load for which the bridge was designed was assumed to be a fill 1 ft. deeper than the actual grade line, this excess providing ample allowance for any additional load reasonably to be expected. Unbalanced live load was given full consideration, but was found to make very little difference in the line of pressures. An effort was made to approximate the stiffening effect of the groins by figuring those sections of the main arch as having greater moment of inertia than that obtained by the formula $(bd)^3 \div 12$. This proved to be a refinement of theory without practical result, and it was abandoned in the later calculations.

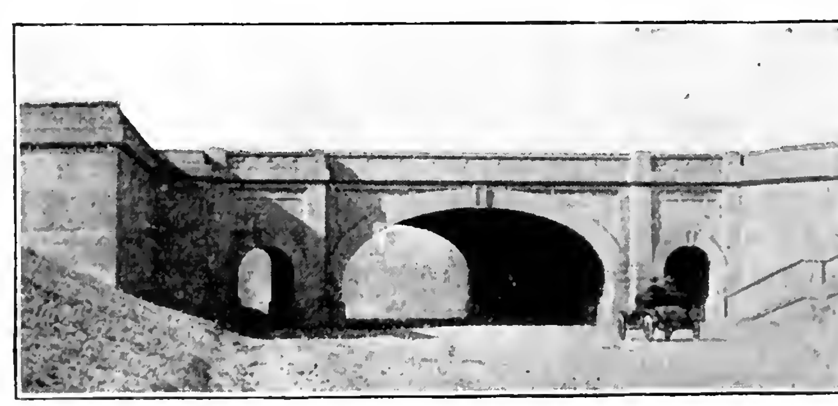
Features of Design—Owing to the fact that each relieving arch springs from a position on the haunch of the main span at which the transept and main arches act to stiffen each other, it was considered proper to analyze the relieving arch on the assumption that its abutments are rigid.

The stress conditions in the groins were investigated on the following basis: The line of pressure of an arch as usually determined is really a cross-section of a surface of pressure. The surfaces of pressure for the several intersecting arches were intersected in lines corresponding somewhat closely with the physical groins of the arches. These lines were then divided into short segments, the thrust of each arch was determined for each segment of the intersection and, being concurrent, these forces were readily composed into a resultant thrust on each segment, from which a line of pressure for the groin arch was drawn. No effort was made to apply the elastic theory to the groins.

Having a line of pressure, the width of groin band required to resist the thrust could be determined. At the haunches, near the sidewalk piers, this figured width of groin band was such that it was regarded as improbable that the material would so adjust itself that the maximum stress along the line of the groin would be satisfactory. Compression reinforcement was introduced, therefore, at these haunches.

It will be seen that the problem did not lend itself to complete scientific analysis. Theory offered only a fair guide as to the conditions of internal stress, and it was necessary to make many of the determinations with but little aid from mathematics. In the early stages of the study of this problem it became apparent that any refinement of theory was unjustifiable and possibly misleading because of the probable influence of variations in the unknowable factors.

The limiting stress in the concrete was taken as 450 lb. per square inch, but this was not even closely



COURT AVENUE SUBWAY AND CURVED STAIRWAY TO CAPITOL GROUNDS

approached except at points where reinforcement was added. Thus, compression reinforcement was introduced at the haunch of the main arch and in the sidewalk faces of the piers in order to give maximum stresses of 450 lb. in concrete and 7500 lb. in steel.

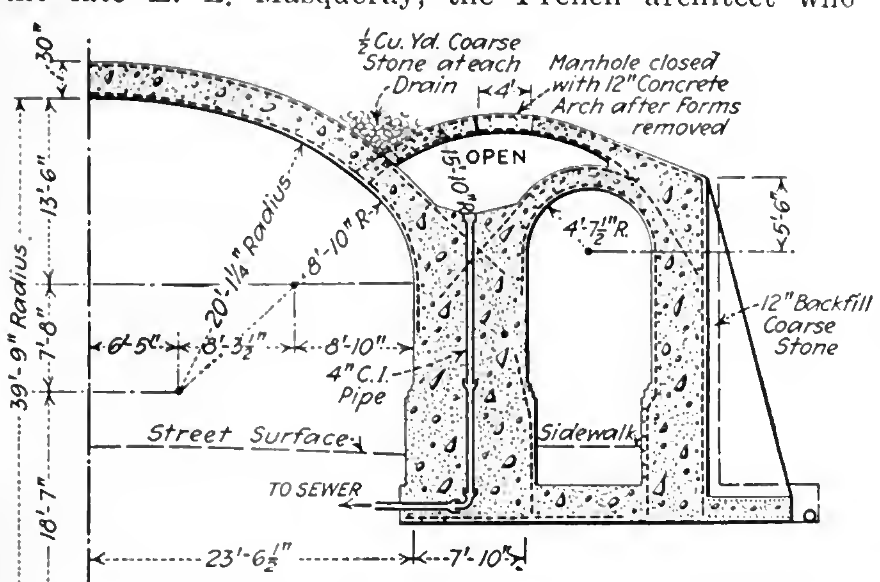
Concrete of the usual proportions of 1:2:4 was used and was made with screened gravel. To insure a smooth working mixture and to avoid staining of the surfaces by moisture, the addition of hydrated lime was specified in the proportion of 8 lb. of lime to each sack of cement. No other waterproofing was specified, except that joints between the work of two shifts were to be coated with elaterite to a depth of 4 in. from the back of the wall as precaution against seepage. Exposed surfaces were finished with cement grout and

ARCH FORMS AND CONCRETING PLANT FOR COURT AVENUE SUBWAY

machined with a surfacing tool after removal of forms.

Footings are seated in the firm gravel soil and on hard shale at some places. No foundation piles were used. Slabs extending under the sidewalk to the abutment footings form braces between footings of piers and abutments. All footings are designed for a pressure not over 2½ tons per square foot on the soil.

The architectural design was made originally by the late E. L. Masqueray, the French architect who



HALF CROSS-SECTION AT PIER SHOWS RELIEVING ARCH CONSTRUCTION

had been chief of design of the Louisiana Purchase Exhibition in St. Louis in 1904. After Mr. Masqueray's death the firm of Slifer, Lundie & Abrahamson, architects, St. Paul, Minn., succeeded to his practice, being organized by men who had been closely associated with him. P. E. Stevens, St. Paul, was the consulting engineer. The Koss Construction Co., Des Moines, Iowa, was the contractor. This bridge was completed in 1917 at a cost of about $68,000.

Columbus Channel Improvements Make Progress

Excavation for widening the Scioto River channel for flood protection at Columbus, Ohio, is about 20% completed. Work was retarded by war restrictions, but reasonably good progress has been made, and most operations will speed up as the season advances. About 90% of the required land has been purchased, and some 150 of the 200 buildings in the way of the widening operations have been wrecked. Concreting has proceeded steadily during the winter, as has excavation for retaining walls and bridge foundations. R. H. Simpson is the engineer in charge of channel improvements.

Associated General Contractors Adopt Constructive Program

IMPROVEMENT of contractual relations, encouragement of sound business practices, and coördination of construction interests, are the broad tasks set for accomplishment by the Associated General Contractors of America. Action will be taken through committees supplied with information and data collected by the secretary and a force of clerical assistants and special investigators to be developed as the need arises.

As recently completed and approved by the directors of the association, the program of operations is: (1) To promote better relations between owners and their architects and engineers on the one hand and contractors on the other hand; (2) to improve and maintain standards in the conduct of work; (3) to combat unfair practices; (4) to increase construction efficiency; (5) to support contractors and contractors' associations in efforts to rectify conditions of an unsatisfactory character; (6) to encourage those methods of contracting for work which relieves the contractor of improper risks; (7) to encourage sound business methods tending to raise the standing of contractors in the business world.

Besides the committees having charge of the routine affairs of the association, there are committees on contracts, legislation, labor, publicity and education, associated organizations, building codes, mutual aid, cost accounting, ethics, and safety. The committees named will conduct the professional work of the association. General directions of procedure have been laid down for each of the seven subjects of the program. Particular effort will be made to push the work and items 1 and 6 of the program.

Better relations between owners and contractors are to be established as follows, as the program states: (1) By teaching owners that the association stands for high ideals and that membership guarantees the reputation of the contractor for skill, honesty and responsibility; (2) by securing a more universal adoption of the cost plus sliding scale fee contract, thereby making the contractor a representative or agent of the owner; (3) by persuading contractors that the interests of their clients and of the community are identical with their own, and that a satisfied client is an asset of immeasurable value; (4) by treating employees with justice and liberality and by taking an interest in their welfare. Specific measures recommended are: Reducing lost time of men, schooling foremen, encouraging apprenticeship, and reducing jurisdictional disputes.

Contractual relations will be improved by urging the adoption of the cost plus sliding scale fee contract where practicable; by insisting that full information be given when lump-sum bids are required; by compelling elimination of the usual clauses placing on the contractor all unforeseen risks and the clauses requiring the contractor to deliver a finished project regardless of what the architect or engineer forgot to specify or show, and by studying and possibly working out a practical arrangement for quantity surveys.

Membership and income have reached a volume which guarantees the means for beginning the committee work. Headquarters have been opened at 111 W. Washington St., Chicago, with Secretary G. W. Buchholz in charge.

Maintenance Data on Twenty-Eight Sections of Test Road

Accurate Records Kept by Philadelphia City Show Relative Cost for Various Types—Traffic Census of Road

IN 1913 the City of Philadelphia laid a test road from Byberry to Bensalem, using five general types of construction in 28 sections, which varied in the details of construction and materials. The types were those ordinarily used for suburban highways. During the six years that have elapsed, considerable amounts of money have been expended in repair. It is now possible to get a preliminary idea as to the value of the various types. To make the data available to the public, the city authorities have prepared a detailed report each year of the condifion of the road and the traffic on it. The tabulations given herein were compiled from a forthcoming report.

The selection of materials, mixing and application to the road were completely described in *Engineering Record* of Dec. 6, 1913, p. 628. The data were kept in great detail, so that at any time it could be known just what the conditions were. Subsequent records of repairs have also been kept in detail as regards the various sections, but where several kinds of bituminous material were used in the same section the maintenance cost for each is not contained in the above-mentioned report. Many of the sections have recently been repaired, and are reported in good condition.

The original road was of water-bound macadam, and in reconstructing it the old surfacing was preserved as far as possible. Most of the bituminous sections were simply surfacings for this old macadam, which was shaped up sufficiently to make an even foundation. In the case of concrete, brick and Bicomac, which had concrete bases, more disturbance of the water-bound surface was necessary.

Five different general types of construction were used: Mixed bituminous; concrete, generally with a bituminous mat; vitrified brick; bituminous macadam; penetration; and Bicomac laid upon a concrete base. A number of different stretches of each of these types were laid, with the exception of the Bicomac, and various mixtures with both tar and asphaltic cement were used in the mats and surfacings.

In considering the mixed bituminous type, all sections in which the aggregate and bituminous cement were machine mixed are considered under one head. In nearly all cases, trap rock was used for the aggregate. The sections 1, 2, 6, 7, 11, and 12 are described as in fair to good condition, slightly wavy, with longitudinal and transverse cracks in some of them. Table I

TABLE I. COST, MAINTENANCE AND CONDITION OF SECTIONS OF BYBERRY AND BENSALEM TEST ROAD, PHILADELPHIA, PENN.

			Surfacing				Maintenance

gives information as to the general construction and maintenance costs of the various sections. The highest cost of maintenance was on Sec. 1, which was about 17c. per square yard per year, while the lowest was Sec. 2, which was about 5 mills. The average cost per square yard per year was about 4c. If Sec. 1, which is abnormally high as compared with the others, be omitted, the cost per square yard per year averages about 1c.

Concrete with Various Carpets

Concrete was used for paving four sections, 3, 5, 9 and 14. Of these, sections 3, 5 and 14—the last named of which was of the Hasson type—received originally bituminous mats. These mats failed badly, and were replaced in each case in 1916, by the use of various methods. In 1918 all sections were resurfaced with 1-in. binder and 1½ in. of top, forming a sheet-asphalt surface. In figuring the yearly maintenance the resurfacings were included. Sec. 9 was constructed with bituminous mats of various kinds, one division being left plain concrete. This section had worn so badly that 860 yd. had to be replaced in 1914, after which a bituminous mat was again applied. The section is reported in good condition. The lowest maintenance cost of the concrete sections per square yard was 10c., while the highest was 32c. The average maintenance cost per square yard per year was 26c. The proportions used for this work were 1:3:6, with the exception of the Hasson type, which was grouted with 1:2 grout. It would seem that where very thin mats are used it is almost impossible to make them adhere to the concrete surface.

Vitrified Brick

Vitrified brick was used on seven sections, 4, 8, 10, 13, 15, 18 and 26. A 4-in. concrete base was used with sand-cushion and grouted-brick top. Very little maintenance was given to these sections during the six years. Only two sections received any repairs at all—No. 4, with 1c., and No. 15, with 2c. per square yard per year. There were longitudinal and transverse cracks in many of the sections, and the repairs consisted of filling these with Tarvia and torpedo gravel.

Bituminous Macadam, Penetration

Bituminous penetration 3 in. thick was used upon eight sections, 16, 17, 19, 20, 21, 22, 23 and 24. Many kinds of bituminous cement were used, and the repairs consisted of some patching of holes and a seal coat applied in 1916. The condition is described as generally good, some sections being slightly wavy, while others have longitudinal and transverse cracks. In some cases the edges are ravelling. The lowest maintenance was for Sec. 24 at 1.5c., and the highest on Sec. 17 at 13c. per square yard per year. The average for the entire eight sections was 5.9c. per square yard per year.

Sec. 26, known as a Bicomac pavement, was laid upon a 4-in. concrete base and was applied by a cold-mix method, using emulsified asphalt. The stone was thoroughly coated with the asphaltic emulsion, the sand and cement were mixed and added to the coated stone, and the whole was thoroughly saturated again with the solution. The surface is reported to be wavy and shows signs of disintegrating. The average cost of maintenance per square yard per year was about 3c.

Table II shows a traffic census, taken between the hours of 5 p.m. and 9 p.m., in the summer, autumn, winter and spring, and on Friday, Saturday, Sunday and Monday, for the years, 1914, 1915, 1916, 1917 and 1918. Large increases in the number of light and heavy motor trucks will be noted. The traffic was the same over all the sections.

Professional Consciousness Must Be Developed Through Service

PRIMARILY, an engineer is "a man whose life is devoted to promoting and planning things that actually happen," according to S. M. Swaab, who recently addressed the Philadelphia Association of Members of the American Society of Civil Engineers. The engineer is "slowly but surely assuming his rightful position in the world," he continued, and stated that the relation which professional engineers bear to modern business and the rate of their compensation will depend upon the degree to which they individually develop a professional consciousness through service and succeed in securing their share of the proceeds of their work. The following short abstracts are taken from his development of this idea.

In his financial relations to the public, the engineer should be over-scrupulous, so that it shall never be said of him that he, like so many others engaged in business and in professional pursuits, has developed a sordid money-sense; but he should undoubtedly have a well balanced commercial vision of the fitness of things and the relation of the technical effort employed to the results and benefits accruing therefrom. There is no question of the fact that as engineers are usually recruited from the ranks of those who are required to maintain themselves by their individual efforts they should see to it that early in life they get on the right track. Ninety per cent., or probably more, of all engineers are employees rather than employers, and for the reason that the engineer usually is entrusted with the conduct of work which primarily is, or at least is intended to be, revenue producing, he, like any other laborer, to use an oft-quoted expression, is worthy of his hire.

In case the profit incident to his work is shared by others, which is usual in engineering works, he should certainly know sufficient of the gentle art of securing for himself a liberal share of the proceeds of his work—not to let the other fellow get all of it—and he should recognize that it is worse than foolish to use his God-given vision, his brains and his professional attainments solely for the aggrandizement of others and entirely for their financial benefit.

He should, therefore, use every honorable means to secure for himself an adequate share of the results of his ingenuity, not alone for the actual effort involved, but also sufficient to compensate him for his "knowing how." Working for a weekly or monthly, or, in fact, any fixed stipend should be discouraged, as is the practice of that master of organization, Charles M. Schwab, whose method is to allow every man to participate in the profits derived from any piece of work in which he may be directly interested.

Evidently, the relations of the engineer and the public are reciprocal, and unquestionably, and above all and all of the time, *our first duty is service;* service without stint, service to the utmost, and this means the best that is in us. Second, the public owes us adequate recognition and remuneration commensurate with our efforts. But first, foremost and above all else, the first duty of the engineer is service.

Grit Chamber and Fine Screens for Part of New York Sewage

First Plant to Treat Sewage from Manhattan Borough—Eductors Clean Grit Chambers—Two 14-Foot Riensch-Wurl Screens

BY CHARLES E. GREGORY

Engineer of Drainage and Sewage Disposal, Borough of Manhattan, New York City

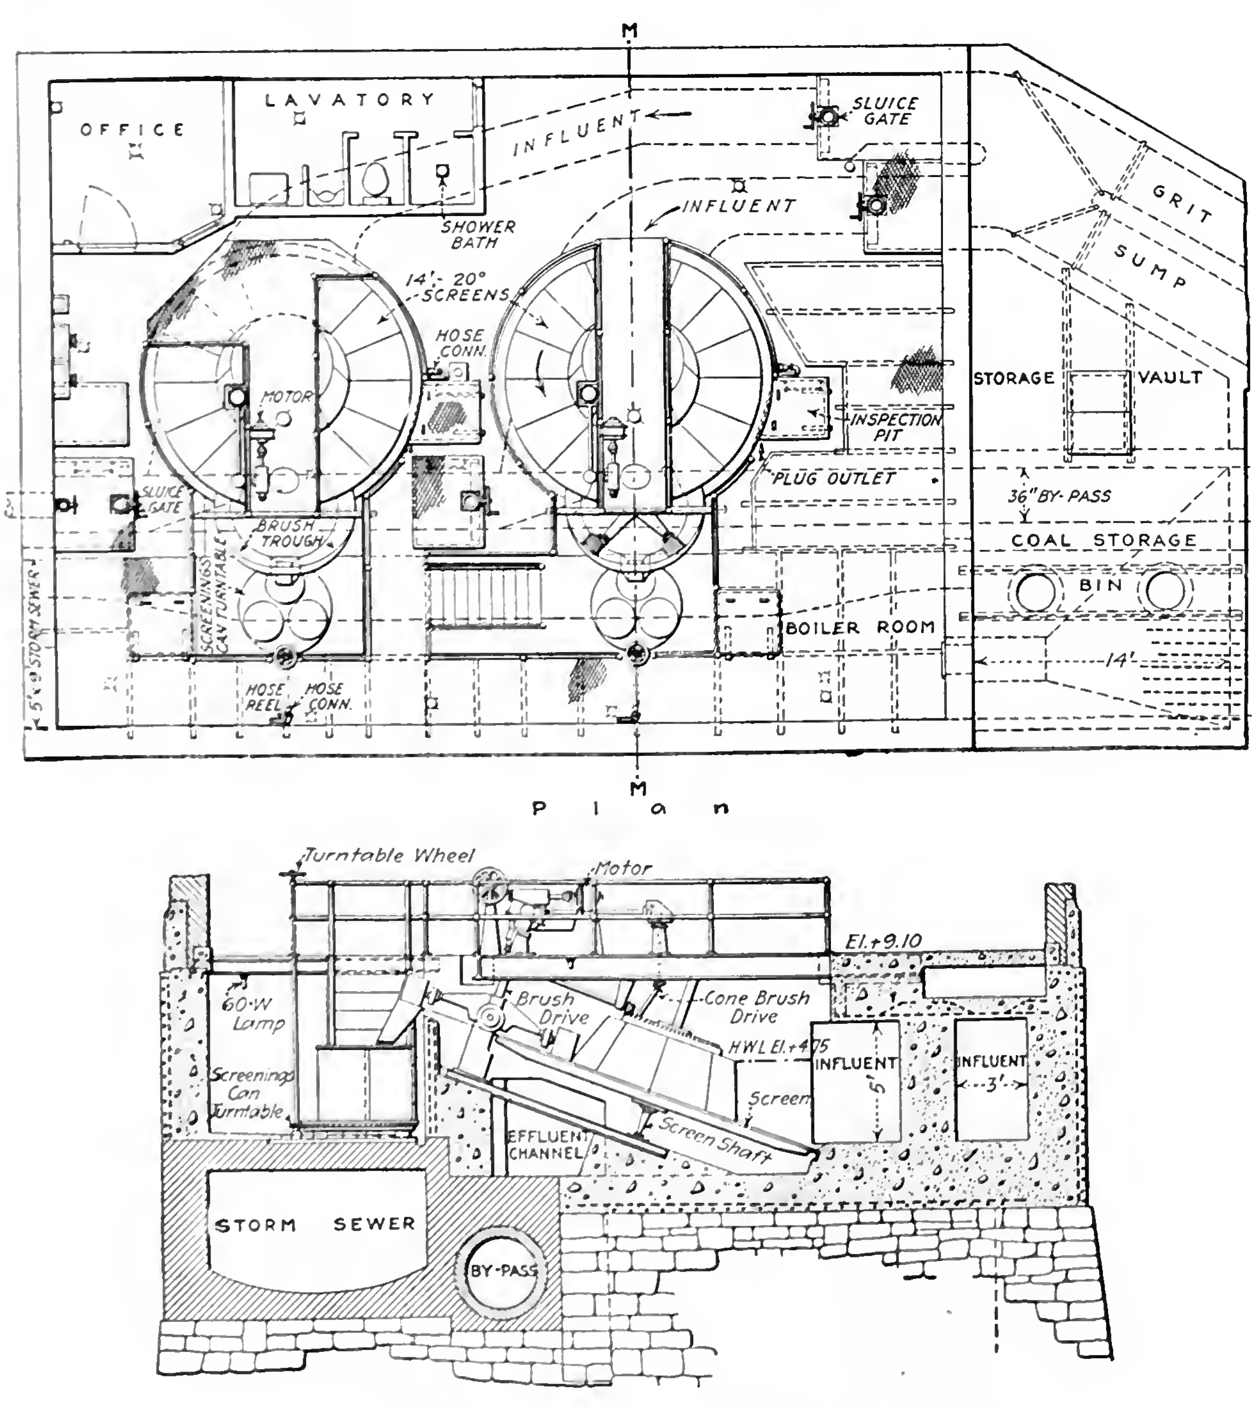
A GRIT chamber and a pair of fine screens of the revolving-disk type, recently put in operation at the foot of Dyckman St., is the first sewage-treatment plant to be built in the Borough of Manhattan, New York City. It is the first step in a comprehensive plan to control pollution of the waters of New York harbor, based on studies begun in 1903. The large volume of harbor waters, with tidal currents and upland fresh-water flow, affords favorable conditions for disposing by dilution of the 500,000,000 gal. of sewage a day produced by New York City, but because of the rapidly increasing ratio of sewage to diluting water serious nuisance exists in various parts of the harbor.

The Dyckman St. sewer, like others in New York City, is a combined sewer. It serves an area of 345 acres in the upper part of the island, of which area about 17% has been built up with apartment houses. The present maximum dry-weather flow is about 3.5 sec.-ft. As originally built, the sewer, of the brick-arch type, was 7 ft. wide by 5 ft. high, and it discharged into the Hudson River at the edge of the high-water shore line. The accumulation of sludge along the shore caused a nuisance to sight and smell.

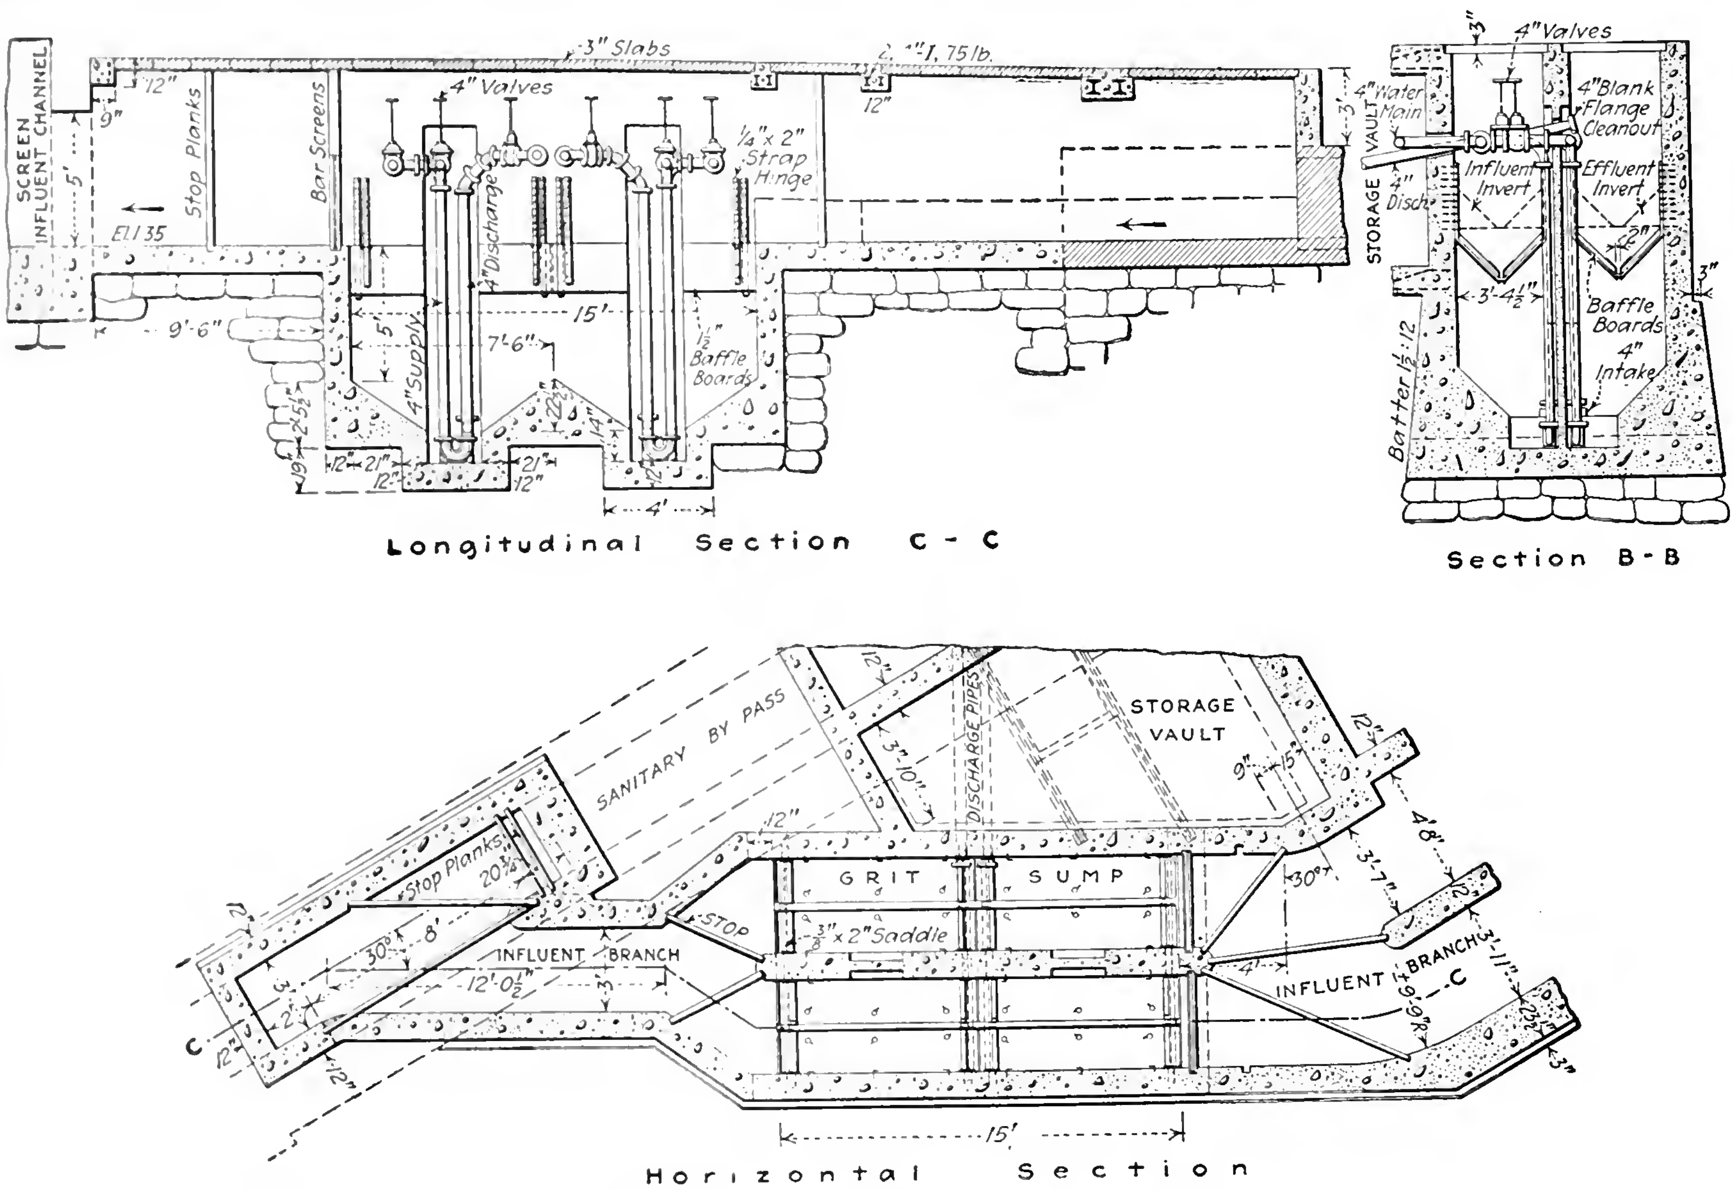
The dry-weather flow is diverted from the Dyckman St. sewer at a point about 1100 ft. above the outlet and carried through a sewer of flatter grade delivering the sewage at an elevation sufficiently above high tide to pass it through the treatment plant and a submerged outlet and discharge it by gravity on the river bottom about 100 ft. from the screen house in more than 40 ft. of water. The bottom of the river at this point is rock and is swept by strong tidal currents.

Outside the screen house provision is made for guiding the flow from the diverting sewer either into a bypass or into the grit chamber from which it passes to the screens. No regulator is employed at the upper end of the diversion sewer, as any excess quantity reaching the screens will flow over adjustable stop planks into the bypass or back into the storm sewer as soon as a maximum depth is reached on the screens. In this way reliable regulation is secured automatically, without making use of a device with moving parts, or loss of head.

The grit chamber is of the two-story type, and is equipped with Otterson eductors for cleaning. It has not been in operation long enough to furnish any reliable data, except to demonstrate the practicability of the cleaning device, which works under the head of water in the local water mains. The diaphragm separating the chamber into two stories serves to maintain a velocity in the upper chamber sufficient to carry over all the lighter organic matter, even though the lower chamber is empty. This would be impossible with a one-chamber structure. The present installation of screens has an estimated capacity of about 10,000,000 to 12,000,000 gal., which is one-half of what is expected to be the ultimate need of this outlet, and the plant has been designed to permit future extension. Two screens of the Riensch-Wurl disk type, each 14 ft. in diameter, set at an inclination of 20° with the horizontal, have been installed. They have an assumed daily capacity of from 5,000,000 to 6,000,000 gal. each, and are inclosed in a neat brick building about 48 ft. long and 35 ft. wide. The screenings are brushed from the disks into galvanized metal cans which rest on a platform; the latter is revolved as each can is filled, to bring the next can in place to receive the screenings. The cans are removed



THE GRIT CHAMBER IS FITTED WITH EDUCTORS



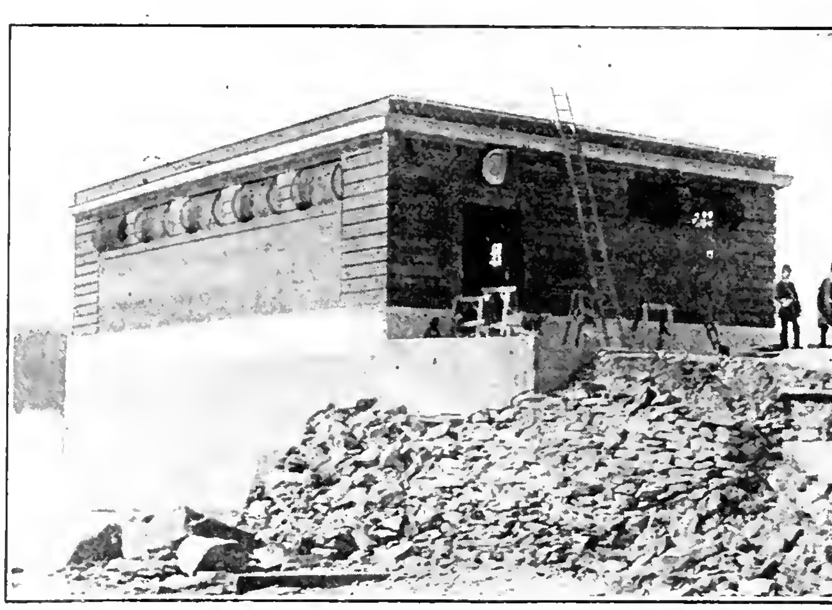
SECTION THROUGH SCREEN HOUSE OF NEW YORK SEWAGE-TREATMENT PLANT

from the revolving platform by an electric hoist which operates along a 10-in. I-beam upon which the cans may be transported to either the shore or water side of the building for loading either into boats or trucks for removal to a suitable dump, reduction plant or incinerator. At present, and until other plants have been developed, screenings are taken to the nearest street-cleaning dump and disposed of with road basin detritus and garbage.

Each screen is operated by a 2½-hp. motor. The screen disk plates are manganese bronze. The contractor was required to demonstrate the screen with apertures of various widths, the smallest being $\frac{3}{64}$ in. wide and 2 in. long. Piping for spraying the screens with hot water or other cleansing or antiseptic solutions is provided. The floors and walls of the building are finished smooth with rounded corners, so they can be washed down with streams from hoze nozzles. This especially applies to those parts liable to collect sediment or spatter from the screenings. The influent and effluent channels are provided with sluice gates for controlling the flow. One corner of the building is partitioned off into a small office and wash-room. The windows are all about 10 ft. above ground and are screened to exclude flies. Additional light is provided through skylights in the roof.

The contractor was required to operate the plant 30 days to demonstrate its mechanical perfection and determine which size of opening was best fitted to the local conditions. The smallest opening tried was $\frac{3}{64}$ in. wide and 2 in. long, and collected 50 % more screenings than the $\frac{4}{64}$-in. opening. The larger openings were not tried, for obvious reasons. The loss of head on the $\frac{3}{64}$-in. opening, when 2,000,000 gal. of sewage were flowing through about 25% of the available area of one screen, varied between 1 and 2 in. When a less area was used there was a decided increase in loss of head as well as a decrease in the quantity of screenings removed.

The sewage at this outlet is considerably weaker than typical Manhattan sewage. Samples taken at various times show that it averages about 150 p.p.m. suspended



DYCKMAN STREET SEWAGE SCREENING HOUSE

solids. The screen plates with smaller openings removed from 21 to 28 cu.ft. of drained screenings in eight hours. The estimated flow for the corresponding period varied from 520,000 to 1,000,000 gal. While no records other than of the quantity of screenings removed were kept to determine accurately the percentage of purification, a comparison of the screenings removed with the

usual total suspended solids in the sewage shows a removal of from 15 to 40% and an average of 32%, which indicates that the expected 20% average removal of suspended solids will be more than accomplished. Often the forenoon rate of removal was double that of the afternoon.

A final decision as to the efficiency of the screen will depend upon results obtained during a considerable period of operation, and it would not be without precedent if some materially different and more reliable results were obtained through such an operation.

On account of war conditions, the contract price for the plant was materially more than was anticipated. The total cost, including grit chambers and building with deep foundations below tidewater, was $77,000.

Maintain Earth Roads by Patrol Contracts in Kansas

State Highway Department Has General Supervision but Lacks Power of Initiation—Machinery Counteracts Labor Shortage

HIGHWAY maintenance by the patrol contract system has been used heretofore in Kansas with what have been considered very satisfactory results, but last year, on account of the labor shortage due to the war, it is said to have failed in many places, the farmers refusing to leave their own work to drag the roads. The county engineers, who work under the supervision of the State Highway Commission, have been forced to adopt various forms of labor-saving machinery and take over the maintenance of long stretches of road with their own gangs. While the state department has general control of the work, it has little power of initiation, and therefore has to wait for action of the people, instead of doing constructive planning.

Maintenance in Kansas consists mainly in the dragging and light grading of earth and gravel roads, since hard-surface construction exists on but a very small part of the highway system. Special attention, therefore, has been given by the State Highway Commission to the organization and methods of execution for this class of road work. While maintenance is under the charge of the county and township authorities, it is subject to supervision of the commission, whose approval of plans is required, and which has indirect control of the county and township funds.

For maintenance of earth roads the commission has arranged a road-dragging and patrol system. The county commissioners and the township highway commissioners award contracts to local drag men or patrolmen, covering specific sections of county or township roads, these sections, varying in length from three to seven miles. As far as possible, the contracts are drawn for one year. Besides dragging the road after each rain, the patrolman is instructed to take care of other maintenance matters, including minor repairs on bridges and culverts. The larger repair and construction jobs are handled by the county engineer or the township road overseer.

Printed instructions for the drag men and patrolmen are not issued by the highway commission, as conditions vary so widely in different parts of the state. County engineers give their own instructions, which usually provide that the roads shall be dragged after every rain that is heavy enough to allow the earth to pack after dragging. The patrolman is furnished usually with a steel drag, a slip scraper and a shovel. Any other tools he may find necessary he must furnish for himself.

Standard forms of contract are employed by which the drag contractor agrees to "drag and care for" a specific section of road for a specific period of time; also to provide a substitute when necessary. He agrees to do the dragging at such time and manner as required by the county engineer (or the township overseer) and to report this work promptly on cards furnished for the purpose. He must also keep informed of the condition of the road and report promptly any damage to culverts, bridges or grade.

The payment varies in different parts of the state but averages from 50 to 75c. per mile for a single round trip, $1 to $1.25 for a double round trip and $1.50 to $2 for a triple round trip. For repairing culverts or bridges and for any other service ordered the pay per hour is about 35c. for each man and 60c. for man and team. The postcard for daily report shows the date and section, the number and location of miles dragged once or twice, and the hours and location of extra work for men and men with teams. The claim or voucher made out each month is a sheet showing this daily information and is sworn to by the contractor.

Machinery Meets Labor Shortage

Labor supply is now the greatest problem encountered but the local patrol system is reported to have worked satisfactorily until last year, when several counties found it almost impossible to get patrol work done, as help was so scarce that farmers did not care to neglect their own work to handle patrol contracts. The engineers in some of these counties arranged for dragging long sections of road by motor trucks or light tractors, thus avoiding the use of teams. In some instances, where the soil is of such a character that to drag in this manner would prevent covering the road at the proper time after the rain, it has been found advisable to use a road planer or a light grader drawn by a tractor or truck, which will smooth up the road. If a little moisture is present the earth will usually compact into a good surface for traffic.

Many counties and townships found it impossible to obtain sufficient teams for grading their earth roads and purchased tractors and heavy motor trucks for the work. They found this plan much more satisfactory. One county engineer, having 1000 miles of road of which 126 are county highways, plans to keep a two-man gang on the earth roads continually with a tractor, grade and bunkhouse on a motor truck.

Where heavy motor-truck traffic is carried on gravel and earth roads, dragging is usually insufficient to maintain a good condition, and light graders are sometimes used. Under ordinary traffic conditions, however, dragging is the only type of maintenance that has been found satisfactory for such roads. Until such time as hard surfacing can be applied to the main traveled highways, dragging must be relied upon to maintain the roads. Oil has been employed on some roads having heavy motor-truck traffic near cities, but the engineers state that this has not proved satisfactory.

The Kansas State Highway Commission is composed of three members, of whom the Governor, Arthur Capper, is chairman. M. W. Watson is acting state highway engineer, during the absence of W. S. Gearhart on military service. F. W. Epps is bridge engineer.

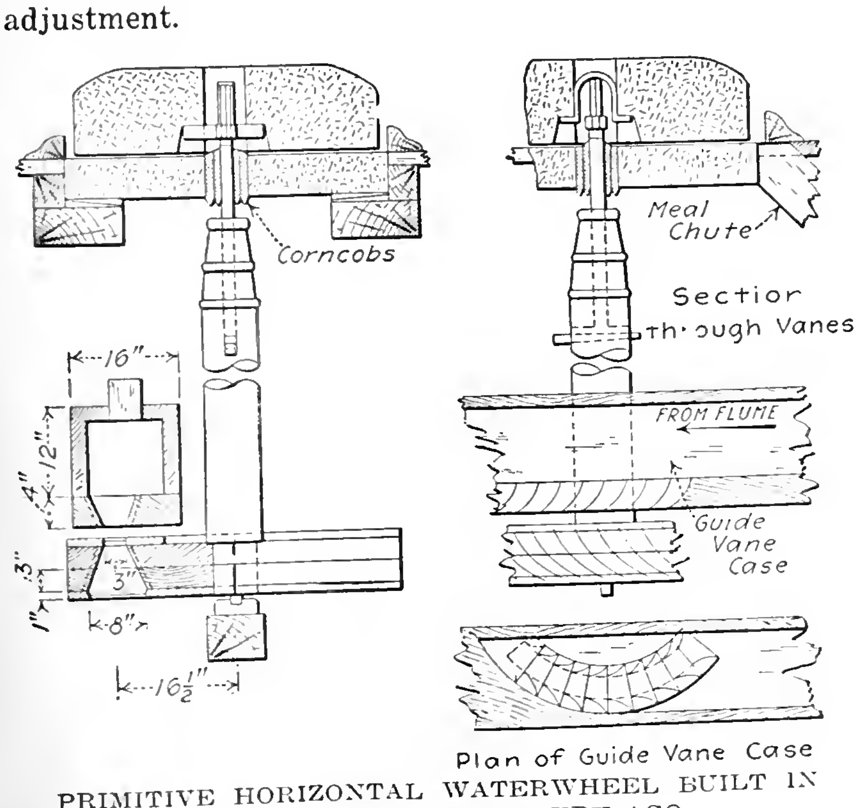
Old Southern Mill Has Curious Horizontal Wheel

Such Grist Mills Though Inefficient Have Value in These Days of Railway Freight Congestion and Grain Shortage

BY H. K. HIGGINS
Copperhill, Tenn.

THERE are scattered throughout the United States a number of old grist mills which in spite of advances of civilization, with its centralization of manufacture and production, still efficiently serve local communities. In a recent trip through the mountains of northern Georgia the writer came across one such mill which has a curious horizontal waterwheel of modern design though primitive construction. Its details seem to warrant description.

The essential part of a grist mill is the two millstones with their characteristic grooves on the grinding surface. These can be of several varieties of stone, natural or artificial. Usually some variety of local stone is available in any country where water power is available. The stones in this case appear to be of a variety of granite and give evidence of having been fully effective. The upper or moving stone is carried by the vertical shaft through two yokes at right angles, let into four notches cut into the lower surface of the stone. The lower stone, which is much thinner, is carried on wedges on heavy beams. Both stones have an axial hole of about 6-in. diameter. The shaft where it passes through the lower stone is "babbitted" with corncobs, an effective if somewhat crude device. This iron shaft or gudgeon is attached to the wooden vertical shaft by a T-shaped head which fits into a long slot in the shaft and is secured by oak fillers and iron bands. A taper key below it provides means for adjustment.



PRIMITIVE HORIZONTAL WATERWHEEL BUILT IN GEORGIA HALF A CENTURY AGO

The casing around the stone is not shown, nor the feed hopper and its shaking valve or feeder. The latter is a grooved plank hung on leather straps and jarred by a multiple cone on a short vertical extension of the shaft. Of course this mill does not bolt the flour, but grinds as fine as desired. A bolting device could easily be added.

The waterwheel is a most ingenious adaptation of the turbine principle all worked out in wood (oak) with the single exception of the wheel and guide vanes, which are evidently iron (not steel) and show little evidence of wear or corrosion. No one knows just how old they are, but the rest of the wheel has been in use 40 years at least, and so have the vanes. The wheel proper is built up of two thicknesses of 3-in. and two of 1-in. planks, pinned, nailed and probably dovetailed together. The vanes or buckets are in grooves and are retained by the outer layers of plank. The vanes curve about 1½ in. and the chord sets about 45° from the plane of the wheel. The water is led to the wheel through a guide-vane box made from two timbers about 4 x 12 x 16 in. The 12-in. timber is hollowed out and inverted over the 4-in., which carries the guide vanes set radially in grooves in a tapered slot. The wheel is about 33 in. in diameter to center of buckets. These taper from about 3 in. at entrance to 8 in. at exit. There is no draft tube—the wheel discharges freely a few inches above tail water.

The dam which serves this mill is about 12 ft. high, stone faced and earth backed. The flume is about 3 ft. or less wide, 10 ft. high, 20 ft. long, and forms the waste spillway as well as the flume proper. The stream is a brook in mountainous country some 1700 ft. above sea level. There is very little water storage; the streams carry heavy burdens of silt and soon fill the ponds.

While such a mill leaves something of efficiency to be desired, the power cost is nil, cost of attendance not excessive, and interest on capital about the only overhead. The capacity is about three bushels of corn per hour, considerably more than enough to keep the tributary community in bread. These mills are occasionally called on to grind barley and rye, making a so-called graham flour, much esteemed as a variant from the customary corn flour. The white variety of corn is almost universally grown in this region. This produces a nearly white meal or flour, making a bread at once palatable and much more wholesome than the starch flour we all know so well.

Such mills have to a great extent come to be considered obsolete for some years past, or since the advent of railroads with easy access of white flour from mid-western mills. They have therefore been allowed to fall into bad order. The experiences of recent winters, with their freight congestions and indiscriminate embargoes, indicate the wisdom of putting these local facilities, so far as practicable, into condition for further use. To some extent this is being done. It is of course also true that in localities remote from railways such mills are and always have been in constant use. Even a few miles over mountain roads means a condition in which such a mill can thrive. There are many unutilized streams all over our country; little capital is required; most communities have plenty of men available for millers; the work is far from arduous. There

should be such mills at ten-mile intervals all over the well watered part of the country. Such a mill with suitable cornfields around it effectually safeguards its community against starvation, even with the railroads worse congested than they have been recently, if that be possible.

Spraying Paint on Corrugated Steel Before Shipment

Speed Requirement and Necessity for Rapid Drying, to Allow Handling, Result in New Methods of Applying Structural Paint

By Thomas M. Wheat

Chief of Engineering Branch, Supplies Section, Division of Military Aëronautics, New York City

When the supply section of the Signal Corps was confronted with the necessity for painting a large quantity of corrugated-steel sheets in the shortest possible time, for use on airplane hangars in this country and overseas, unique erection conditions made it necessary to omit the application of a coat of paint in the field. This called for extreme care in painting and packing the sheets in the shop. Hand painting required a large amount of labor, much floor space, and handling of wet sheets. Machine painting was not practicable, on account of the corrugations, and the painting could not be done before corrugating because of the damage done to the paint by the corrugating rolls.

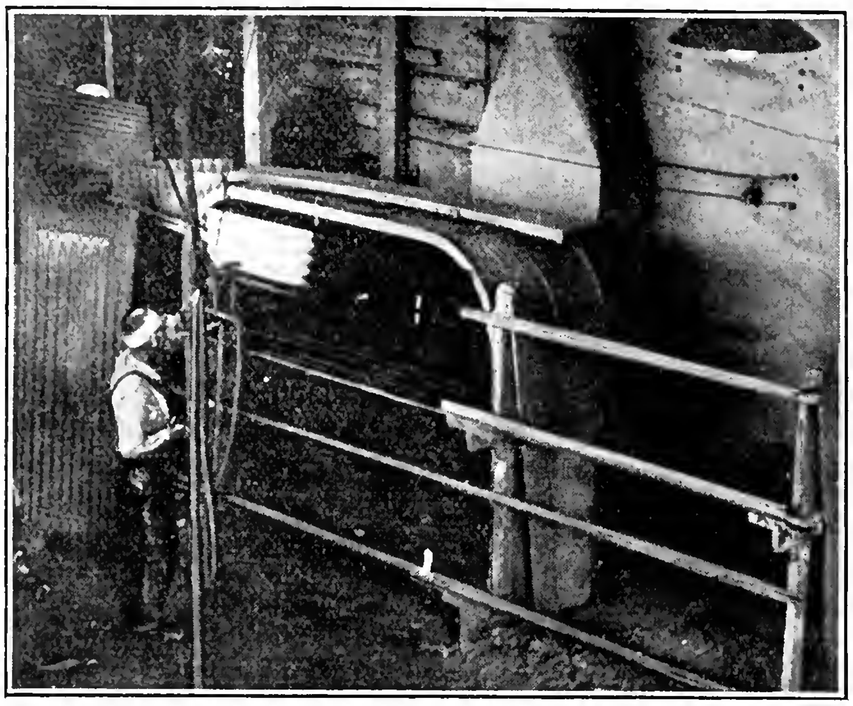
The problem was solved by the use of spraying. Figures are given to show the average surfaces covered per gallon.

This project soon developed into something entirely new. Instead of the finely atomized, delicate jet used on filing cases and such articles, this operation called for a jet 14 in. wide carrying enough actual paint to give a fair protecting coat. The metal paint containers ordinarily used, for example, have a capacity of something like 13 gal., and at the rate of operation maintained these had to be refilled about every hour. This early brought about the purchase of a double set of apparatus—containers, spray guns, hose, etc. This reserve set proved very useful in case of accident, as the layout was such that a shutdown on one gun threw two crews out of action, or about 10 men.

These containers were later abandoned, with the attendant system of air pressures, and there was substituted a gravity feed from barrels on an overhead scaffold.

The sheets required a priming coat of red lead, and this was put on by means of roller machines, before the corrugating was done. Corrugation and fabrication were then completed, and the sheets were brought to the spray operation. Here they were to receive a coat of gray on one side and a coat of green on the other. Hoods were built on the floor, and racks in front of them, for the sheets. Operators wearing gas masks stood before them and sprayed the sheets as shown in the illustration.

The gas masks were necessary at first on account of the peculiar and penetrating odor of the paint. One side of the sheet having been sprayed, the sheet was shoved along the rack to the next hood, facing the opposite direction, where a second operator sprayed the other side. The operation was then completed by hanging the sheet on a traveling chain, by which it was taken through a drying oven. Incidentally, it was discovered that the workman's hands in handling left no mark on freshly painted sheets if his hands were encased in gloves having a surface of emery cloth on the side coming in contact with the paint.



PAINTING CORRUGATED STEEL SHEETS BY SPRAYING

The hoods, as supplied by the manufacturer, were equipped with a 10-in. blade fan at the back, this being adequate for the removal of ordinary quantities of fumes and escaping spray. Not only were these fans inadequate for taking care of the volume of matter to be removed in this case, but quickly became coated with paint and were thus rendered still less effective.

This difficulty was overcome by the installation of an induced draft system by which a 20-hp. motor forced air through a 6-in. pipe into a 36-in. flue from each pair of hoods. The 6-in. pipe was contracted to a 4-in. nozzle in the flue, and the force was enough to remove the spray and fumes, discharging into the open air through a vent in the roof. Several months later it was discovered that a large area of the roof in the vicinity of this vent was covered with several inches of paint. Conduits and gutters were thoroughly clogged —a new form of industrial waste.

An attempt was made to use ordinary brush paint for this work, with indifferent results. The trouble experienced with clogging of apparatus led to the investigation of the question of what constitutes a good paint for spraying. Of prime importance was the feature of "squirtability"; that is, the property of flowing freely through the guns, where the paint is atomized and spread out in a fine fan-shaped spray by a current of air entering the nozzle. It reaches the sheet in the form of minute globules, and must be so constituted that it will flow out in a smooth, uniform coat, notwithstanding the cooling in the jet. An additional requirement of the paint in this case was that of quick drying, and hence this flowing out had to be accomplished in a very brief period.

The specifications called for a paint that would dry

in six hours, and the plan was to force the drying to an hour and a half in an oven at a temperature of 160° F. A paint that will fulfill the ordinary specification of drying "to touch" in a given number of hours is by no means necessarily dry enough to *handle.* Sheets that came from the oven not dry enough to handle and pack directly were stacked on the floor until dry and hard, and this not only took up valuable labor and floor space, but also occasioned unavoidable damage to the paint itself.

The addition of drier was inadvisable beyond a certain point, of course, and it was some time before attention was given to the air-jet agitator used to stir the paint in the mixing barrels and reservoirs. The elimination of these constantly flowing streams of air and the substitution of hand stirring for them led to very satisfactory results in drying. The theory of it seems to be that the jets effected greater evaporation and drove off the lighter, more volatile, drier and thinner liquids.

A point of great interest was the question of how many square feet of metal could be covered with one gallon of paint. During six months' observation at the plant of the Berger Manufacturing Co., Canton, Ohio, it was found that this figure varied greatly. This variation depended, apparently, upon the color of the paint, its specific gravity, the operator, the apparatus and even the weather. The average for a "battleship" gray is 350 sq.ft. per gallon and for an "invisible" green 375 sq.ft. per gallon.

These figures include all the paint actually brought on the premises. Probably 10% of all the paint bought and paid for was wasted. This considerable item was countenanced in the interest of speed, which was a matter of greatest importance. Numerous suggestions were offered for eliminating or reducing this loss, but it certainly never went below 6%. The figures given above are for square feet of sheets in the flat. The Truscon Steel Co., at Youngstown, Ohio, installed a system of automatic spraying, and this may have reduced the loss of paint.

So far as the writer knows, no data are available as to the protective qualities of a paint covering that has been sprayed on. If this structural value is satisfactory the speed of application makes it evident that this method is vastly superior to the ordinary method of hand painting, particularly for the shop coat on structural steel.

Typhoid in the Expeditionary Forces of the American Army

Began to Appear During Offensive Early in November, Due to Extraordinary Exposure—Death Rate Not Unusual

By George A. Soper

Major, Sanitary Corps, United States Army, Office of the Surgeon General, Washington, D. C.

After having been practically eliminated as a cause of disability in the United States Army, typhoid fever has recently made its appearance in the Expeditionary Forces under circumstances of broad, instructive interest. How the typhoid rate was reduced from its high place a generation ago nearly to zero and kept there during the mobilization of our troops in the present war, need not be repeated here. In the permanent American camps, sanitation, particularly as regards water-supplies and sewage disposal, together with vaccination, had eliminated the disease as a cause of anxiety. This dual method of control had proved entirely satisfactory. Its results may be said to represent an ideal toward which American cities and towns should aspire.

Army experience before and since the outbreak in France shows that these two procedures of sanitation and administration are necessary and sufficient in order to control typhoid.

Tyhpoid began to appear in the Expeditionary Forces during the offensive early in November. When, in the fighting in the Argonne, men became very thirsty, they sometimes disregarded their instructions and drank from forbidden, polluted sources. These men were protected against ordinary exposure to typhoid, but they were not, and could not, be made proof against the mass attacks of the heavily infected water.

The conditions which were encountered in the Argonne advance were repeated with certain variations elsewhere. For example, at Nevers tap water, forbidden for anything but industrial purposes, caused fifty or sixty cases. Much the same is to be said of Joinville (Haute Marne). Contact infection accounted for some of the cases which occurred among the personnel attached to hospitals and for the same reason: The danger was wholly unexpected and the dosage was excessive.

It is curious to observe that the rarity of typhoid contributed materially to its spread. Trusting implicitly to the safety afforded by vaccination, in spite of warnings that it does not afford unlimited protection under all circumstances, the thought of typhoid, the measures to be taken to prevent it, and the clinical recognition of the disease, had been banished from the minds of many medical officers.

The early cases which occurred were, therefore, not always promptly recognized, and the necessary steps to prevent contact infection were not always taken. And after it had begun to spread, the typhoid proved no

exception to the rule that epidemics when once started are extremely difficult to stop.

Although there have not been so very many cases in proportion to the great strength of troops employed, the typhoid has been widely distributed in the American Expeditionary Forces. Between Oct. 1 and Feb. 13, the total number of cases of both typhoid and paratyphoid reported was 1011, as shown in detail by the accompanying table. The death rate was not unusual.

The mean strength of the American Expeditionary Forces in France during this period may be taken as 1,833,000.

Cost of Ditches for Reclaiming Idaho Lands

Cultivated Ground Spoiled by Excess Irrigation Water Is Restored by Drainage—Caterpillar Electrically-Driven Excavators Used

By D. W. Cole

Formerly Project Manager, Boise Irrigation Project, United States Reclamation Service, Boise, Idaho

More than 120 miles of deep drainage ditches on the Boise irrigation project of the U. S. Reclamation Service have been excavated to remove excess water resulting from irrigation. As a result, excellent crops have been produced from land which five years ago were in swamp, but which formerly had been farms and orchards. Herein are presented some data on the general cost of the work.

This Idaho project includes about 143,000 acres of crop-bearing land, in addition to lower cultivated areas of about 100,000 acres in irrigation districts through which drainage waters must pass to reach the Boise River. About 17,000 acres of productive lands having become waterlogged or affected by seepage, the U. S. Reclamation Service, in coöperation with the irrigation districts, undertook to construct a drainage system for the relief of these lands and of adjoining lands into which the seepage was progressing. This work, begun about five years ago, has been completed. More than 5,000,000 cu.yd. of excavation have been made for 120 miles of drains averaging 9 ft. in depth, with a range of 6 to 12 ft.

More than 1600 structures were required, as these ditches traverse a highly improved farming country. Reinforced-concrete flumes carry the larger irrigation canals across the drains; metal and wood flumes serve for the lateral ditches. Large reinforced-concrete pipes are used as culverts in many places under highways, railways and canals. Numerous railway and tramway bridges were provided, and bridges for highways on nearly all section lines; and bridges of the same class were supplied for many farm crossings.

For determining the subsurface water conditions, numerous test pits and borings were located, and underground water contours were plotted. In conjunction with surface topography, these were employed for locating the drainage ditches for the greatest efficiency in tapping the subsurface waters. The entire area to be drained was practically underlaid with coarse gravel of an indefinite depth below the surface soils, 2 to 4 ft. deep.

Discharge of seepage water from the numerous drains ranges from 1 to 80 sec.-ft., according to the length of the drain and the tributary area. A group of the principal trunk drains discharged during 1916 approximately 224,000 acre-ft. of water, of which about 57% was seepage water, 28% surface run-off from irrigated fields, and 15% storm-water run-off in January and February.

Four electric dragline excavators mounted on caterpillars, with 50-ft. booms and 1½-yd. buckets, were the principal equipment. They operate on 440-volt alternating current, furnished at less than 1c. per kw.h. from the project's hydro-electric plant in the Boise River. Transmission line service at high voltage was obtained through contract with the Idaho Power Co., the branch lines at low voltage being installed temporarily by Government forces with the progress of each excavator. A central camp with an electric substation, a repair shop, an electric shop and all necessary accessories was maintained during the operation of the four excavators. The machine efficiency of the excavators is exhibited in one of the accompanying tables.

All four machines were operated in 1916, resulting in 2,660,465 cu.yd. of excavation in the total digging time of 17,732 hours, or 150 cu.yd. per hour per machine. With the rated 1¼-yd. capacity of the buckets this shows two buckets per minute as the average working rate of the machines. The material averaged 2 to 5 ft. of top soil with underlying heavy gravel, streaked with hardpan 4 to 8 ft. deep; occassionally a ridge of hard lava rock made blasting necessary.

Careful cost records were kept for each drain and

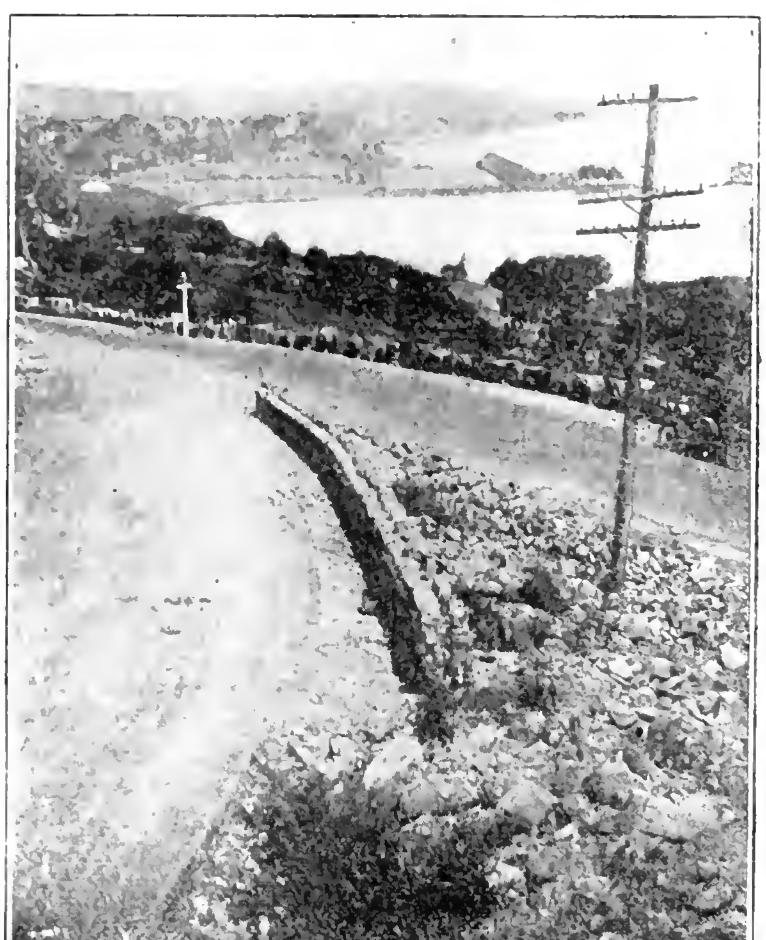
structure separately, and a full report has been compiled showing the length, depth and cubic contents of every drain and the elements of all its accessory structures, with total and unit costs. A tabulated summary with results for one of the three districts is given herewith. The total cost of the work complete was $615,000.

Elimination of Dangerous Road Junction and Its Cost

Deep Rock Cut and Fill Improve Conditions—Traffic Maintained by Sectional Building—Special Drainage System Installed

By Eugene Gedney
Nyack, N. Y.

ELIMINATION of a dangerous junction by the making of a deep rock cut on a connecting road and a deep fill on the main road, and the reduction of the grade of the connecting road from 18 to 10%, were effected on the Short Clove road which connects two highways near Haverstraw, Rockland County, N. Y. Considerable difficulty was experienced in the construction of this road, due to the very hard rock encountered and the trouble produced by numerous springs adjacent to and within the work. Inasmuch as traffic could not be interrupted on the main highway, the deep fill at the junction had to be built in sections, so that there would always be a driveway open.



NEW JUNCTION HAS CLEAR VIEW AND FAIR TURN

Short Clove road, which joins the main river route No. 3 of the New York State highway system, has a very sharp curve at the point of union. Coupled with this, the clear view was obstructed by a high rock ledge, and in the laying out of the new connection the main idea was to get a reasonably good junction with a fair grade and a clear view, and at minimum cost. After several schemes were discarded, it was decided to raise the grade of the main road approximately 10 ft., moving the junction of the two roads to the south about 75 ft. This created a short plateau 40 ft. wide, afforded an unobstructed view to travelers on both roads, and gave those coming from the south sufficient space to turn into the cross road, which was almost impossible before. A photograph of this new junction as constructed is shown.

SPILLWAY FROM SPRING PASSES INTO CATCHBASIN THROUGH DRY MASONRY WALL

The connecting road, which is only 1280 ft. long, is partly in rock cut from 5 to 25 ft. deep. Above this rock the geological formation changes to a soft clay and muck pocket about 300 ft. long and 3 to 18 ft. deep. Underlying the clay pocket there is a stratum of fine sand which contains many springs and considerable seepage water from the adjoining mountains. As soon as the clay stratum was cut through, the seepage and spring water began to run freely, at times nearly flooding the cut. The amount of water encountered is evidenced by the fact that one of the springs near the north edge of the roadway supplied at all times sufficient water for the contractor's steam boiler and other equipment.

To make these unstable soil conditions safe for a roadway, a 6-in. pipe underdrain was laid under the north ditch line and about 3 ft. below the pavement line. Under the south ditch line, where the seepage was less, a blind stone drain was placed. To facilitate drainage into these side drains, a sub-base foundation with porous filler, having a width of 20 ft. and a depth of 24 in., was laid for the full length of this unstable section.

Near the point where the road passes into the rock cut, and 60 ft. to the north, is an exceptionally large spring, for which it was necessary to provide drainage. A concrete apron was built down the side of the cut, and this was connected with the spring by a cement grouted cobble gutter, the drainage passing into a catchbasin in the gutter. This apron and catchbasin are shown in an illustration. The catchbasin is of special

construction and is drained across the roadway by means of an 18-in. pipe, connecting with a similar catchbasin on the other side. Into these catchbasins all drainage from above is carried. In one case it was necessary to form a basin for one of the springs in the middle of the road and lay a special drain from it into the catchbasin. From the catchbasin on the south side and passing through the rock cut, a 12-in. pipe underdrain was laid in a trench 2 ft. wide and 3 ft. deep and covered with crushed stone and small rock. The method of laying this drain is shown in a view (see next page). This drained into an open ditch at the far end of the cut.

Another difficulty encountered was the fact that the side slopes of the clay cut were so unstable that after every rain a part would slide in, blocking the ditches and some of the road. As a protection against these slides, the dry masonry wall, shown about the catchbasin, was built on both sides of the cut.

The rock excavation was also a rather difficult part of the job, as it was done in trap rock that was full of fissures. This made drilling very hard, the run of drill per nine-hour day ranging from 6 ft. to a maximum of 20 ft. On account of this, the contractor endeavored to get along with as little drilling as possible, spacing the holes about 6 ft. apart and drilling from 10 to 15 ft. in depth. It was always found necessary to drill lift holes beyond the bench holes. As the holes were spaced rather far apart, the contractor tried to get as much dynamite into them as possible, and for this purpose the holes were sprung by exploding small charges of dynamite at the bottom, thus enlarging their capacity. In this manner 40 to 50 lb. could be used in each hole.

Two Tons of Dynamite Used

The usual blast consisted of one row of four or five bench holes with about three lift holes 15 ft. back from the face. The average amount of rock loosened by one blast was from 200 to 225 cu.yd. It broke up in rather large pieces, many of them as large as a cubic yard, and the removal of these large stones was effected by means of stoneboats on which they were dragged to a point a short distance from the excavation. Data which were collected show that a total of 1600 lin.ft. of drilling was necessary, and that 4400 lb. of dynamite were used to remove approximately 4800 cu.yd. of rock; about 0.33 ft. of drilling and 0.9 lb. of dynamite for each cubic yard removed.

During the making of the fill upon the main road the contract called for keeping the road open for traffic. This fill was 10 ft. deep on the center line of the road and was 50 ft. deep on the east side, a dry masonry toe wall 5 ft. wide and 15 ft. high being built at its foot in order to prevent it from going upon the railroad property at the foot of the slope. This fill was used as a spoil bank. The method followed was to bring the fill even with the old road; then to build half of the fill up to the new grade, using the other half of the road for traffic; then to turn the traffic over the new fill and raise the other side. This method was found feasible, and traffic on the main road was uninterrupted.

The surfacing of the road consisted of a combination of bituminous and water-bound macadam 20 ft. wide, the middle 10 ft. being bituminous macadam, penetration method, while 5 ft. on either side was of water-bound construction. The water-bound macadam was adopted to take care of horse traffic, as it was thought that the other construction would be too slippery on a 10% grade.

CONSTRUCTION COSTS ON SHORT-CLOVE ROAD
NEW YORK STATE HIGHWAY DEPARTMENT

Earth Excavation	
Labor	
Superintendent, 50 days at $5 00	$250.00
Foreman, 80 days at $4.00	320.00
Common labor, 660 days at $2 75	1,815.00
Carts, 170 days at $3 50	595.00
Total labor	$2,980.00
Materials, small tools, incidentals	90.00
Cost of removing 4,200 cu.yd	$3,070.00
Cost per cubic yard	$0 73
Rock Excavation	
Labor	
Superintendent, 90 days at $5 00	$450.00
Foreman, 10 days at 4.00	40.00
Blacksmith, 60 days at 3.50	210.00
Drill runner, 176 days at 3 50	616.00
Drill helper, 143 days at 2 75	393.25
Total labor	$1,709 25
Materials	512.00
Depreciation of plant, small tools and incidentals	100 00
Total cost of drilling 1,600 lin.ft	$2,321 25
Cost per linear foot	$1 45
BLASTING AND DISPOSAL OF ROCK	
(Average haul 500 Feet)	
Labor	
Superintendent, 100 days at $5 00	$500.00
Foreman, 80 days at 4 00	320.00
Common labor, 1,100 days at 2 75	3,025.00
Teams, 150 days at 6 50	975.00
Carts, 200 days at 3 50	700.00
Total labor	$5,520 00
Materials and tools	
Dynamite (3000 lb. at 28c. and 1800 lb. at 35c.)	$1,470.00
Blasting caps, wire and incidentals	100.00
Small tools, etc	60.00
Total materials and tools	$1,630.00
Cost of blasting and disposal of 4,800 cu.yd	7,150.00
Cost per cu.yd	$1 49
Total cost of rock excavation	$9,471 25
Cost per cubic yard	$1 97
Macadam Surfacing	
Labor	
Superintendent, 15 days at $5 00	$75 00
Foreman, 15 days at 4 00	60 00
Common labor, 55 days at 3 00	165 00
Cart, 5 days at 3 50	17 50
Team, 3 days at 7 00	21 00
Steam roller, 15 days at 15.00	225 00
Incidentals	25 00
Cost of manipulation, 536 cu.yd	$588.50
Cost per cubic yard	$1 10
Materials	
Crushed stone, 850 tons at $2.50	$2,125.00
Tarvia-X binder, 4,740 gal. at 17c	805 80
Tarvia-B cold application (850 gal. at 17c.)	144 50
Filler for bottom course	25.00
Total for 536 cu.yd	$3,100 30
Cost per cubic yard	$5 78
Total cost of macadam per cubic yard	$6 88

On this 0.24 mile of roadway the material excavated amounted to about 9000 cu.yd. Itemized costs of the major items of the work are shown in the accompanying table. The equipment used consisted of one 25-hp. steam boiler, one steam drill, one jackhamer drill and the necessary small tools. The dump wagons, carts, steam roller, sprinkling carts, etc., were hired locally. Crushed stone for the macadam was furnished by the West Nyack quarries, and was hauled eight miles by five-ton motor-trucks. The bituminous material was furnished by the Barrett Co., and the price quoted covers applying. It was hauled about 35 miles in asbestos-covered auto tanks, and delivered at 275° Fahrenheit.

Work was started June 1917, shut down December. 1917, started again in March, 1918, and completed in August, the working time being approximately 300 days. It was impossible to run the job economically on account of the labor conditions due to the war. The large amount of coal used in drilling was due to the necessity.

VITRIFIED TILE DRAIN IS COVERED WITH STONE

of keeping up steam on days when the drill runner did not appear.

The construction was carried on under the Construction Department of the New York State Highway Department, H. E. Breed, first deputy highway commissioner, J. H. Sturdevant, division engineer, and the writer as engineer in charge. Eugene Cavallo, of Haverstraw, N. Y., was the contractor.

Move Equipment and Material for Dam Through Small Tunnel

In Building Dam Everything Had To Go Through 42 x 48-Inch Section of Santa Barbara Water Conduit Then in Service

BUILDING the Gibraltar Dam for the City of Santa Barbara, Calif., involved the unique problem of getting all equipment, materials and supplies through a tunnel four miles long which has a clearance of only 42 x 48 in. The tunnel was built some years ago for the city water-supply. This supply could not be interrupted, so there was always a depth of 12 to 18 in. of water in the tunnel to contend with, not to mention the continuous downpour from the roof in many places. On account of difficulties encountered in driving the tunnel, its alignment is not good. It is lined with concrete for part of its length, the remainder being irregular rock section. The problem of transportation through the tunnel has been effectively worked out, however, and in the first three months of the construction period 15,000 cu.yd. of concrete was poured with but little delay on account of tunnel difficulties.

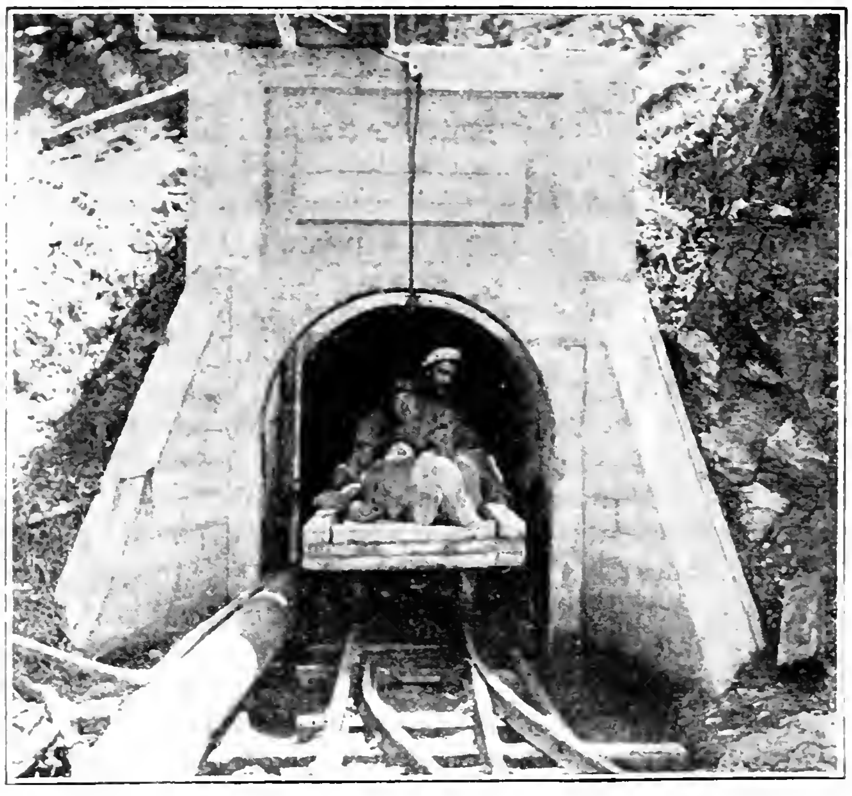
Rails were laid and a 220-volt trolley line was strung through the tunnel so trains could be operated electrically, but in order to secure the maximum clearance mentioned large pieces such as motors, steam-shovel boilers, and other equipment that could not be cut apart, had to be taken through on a special "low" car which was pushed through by hand, a trip that required from 9 to 11 hours. The operation of the tunnel railway is under the direction of the City of Santa Barbara, the cost to the contractor being $2 per ton laid down beneath the aërial cableway near the dam, 2000 ft. upstream from the tunnel.

Trains are operated through the tunnel for 16 hours out of each 24, there being two 8-hour shifts on each train crew. There are four locomotives, one considered a spare, so it is expected that three trains will be in service continually. It is expected that one of these will be loading or unloading while the others are going and coming. A siding was provided midway in the tunnel, so trains ordinarily pass at this point. The time required for a round trip is about an hour. With three trains, allowing for time of loading and unloading, there should be therefore a trainload delivery at destination every 30 minutes.

Cement is taken through in three-car trains, the load being 51 sacks per car. Each car is covered with heavy tarpaulin for protection from the leakage in the tunnel and the splashing from the car trucks. The cement is not unloaded from these cars at the railway terminal, the cars being picked up bodily from the rails by the cableway carrier and hoisted across the gorge to an eminence at one end of the dam.

Between July 9, when the contract was signed, and Sept. 1, when the first concrete was poured, there went through the tunnel piece by piece two 1-cu.yd. mixers, six electric hoists, rock screens, skips, hoppers and a steam shovel which the contractor had selected with an eye to the fact that the boiler would just meet the tunnel clearance requirements. Between shipments of all this equipment there were also handled through the tunnel 40,000 sacks of cement and 275,000 ft. b.m. of lumber. By reason of this expeditious delivery the contractor was able to pour 15,000 cu.yd. of concrete in the first three months; sometimes a day's run was as high as 420 cubic yards.

Getting the larger equipment through the tunnel meant using an oxyacetylene torch to cut each machine to pieces and, after the pieces were delivered at destination, welding them together again with a similar oxyacetylene apparatus. Perhaps the largest welding job was on the big concrete mixers whose mixing chambers were cut neatly in half and successfully welded again at the site of the dam. In fact, of the two mixers that were sent through the contractor finished with one and cut it apart again, and after it had been returned to Santa



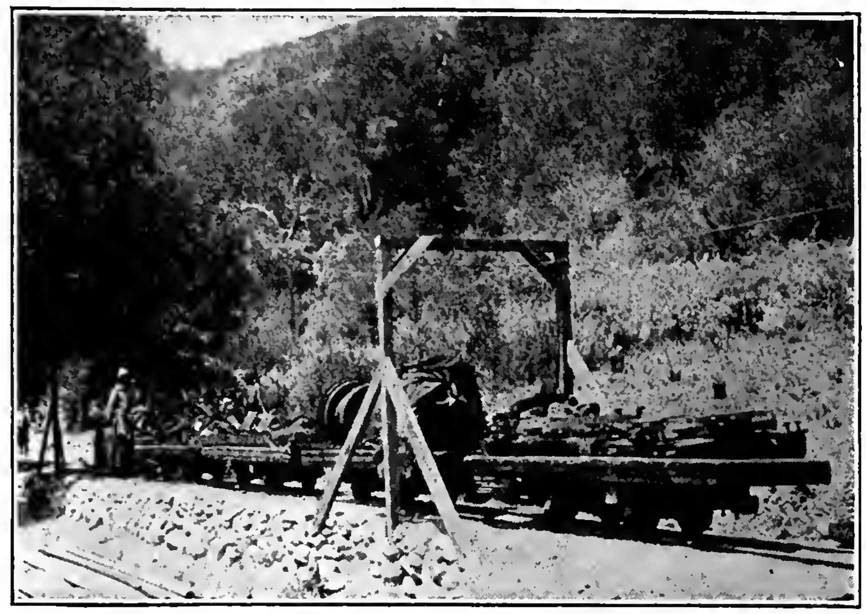
PORTAL OF 4-MILE TUNNEL THROUGH WHICH PASSED ALL MATERIAL AND EQUIPMENT

Barbara it was welded up for the second time and was then still in first-class condition.

The largest assembly job was that of putting together a steam shovel. The miscellaneous collection of machinery had all the general appearance of a wreck. The boiler had to go through intact, but practically all the other large parts were dismantled. The platform and turntable were taken apart, and even the teeth were taken off the bucket. Approximately 1000 rivets were cut out in dismounting the shovel and later put back at the dam.

Special tank cars were built for conveying fuel oil through the tunnel, as the city refused to run the risk of possible leakage into the water-supply system from oil transported in barrels. Dynamite the city absolutely refused to permit in the tunnel, so this had to go by pack horse over a long, rough trail. The work was closed down for the winter in December, but it is expected that it will be completed early this year.

Quinton, Code & Hill are consulting engineers on the work. The contract is being carried out by Bent Bros.



CONSTRUCTION MACHINERY ON WAY TO DAM

and W. A. Kraner, the latter being in personal charge of the work. E. E. Haskell is resident engineer for the city.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Deterioration of Burlap in Waterproofing

Sir—The communication in your issue of Feb. 27, 1919, p. 440, by J. B. W. Gardiner, on "Deterioration of Burlap in Waterproofing," comes to me as a considerable surprise. Mr. Gardiner states "reference to any standard work on industrial organic chemistry will show . . . that it is the most perishable of all vegetable fibers; that even the small amount of moisture in the air will cause it to deteriorate very rapidly, and, finally, that this rate of deterioration is greatly increased where the moisture carries alkali."

This is great news to me. I should like to get a list of the standard works on industrial organic chemistry that make this statement; I should like to know why it is that ever since linoleum and floor oilcloth have been invented burlap has been used as the foundation for the manufacture of this important product. I should like to know why burlap when used in floor coverings does not rot or deteriorate even if water soaks in between the seams, and I should also like to know why the sandbags used in Europe during the great war for the protection of buildings, particularly, and for the protection of the parapets of trenches, stood up so thoroughly and completely even though they were soaked with rain and mud, and the burlap bags served a remarkably useful purpose.

Furthermore, I should like to know by what process of reason or chemistry cellulose fibers are attacked by weak alkali. I know from my own experience that the animal fibers like wool are attacked by alkalies, and vegetable fibers like cotton or flax resist alkali; in fact, the well known method of the analysis of wool which is mixed with cotton or cellulose fiber is to apply the caustic alkali test. It is also very well known that the method of separating wool from cotton is with a weak solution which attacks the cotton and leaves the wool intact.

The oxides of sulphur generated in many of the waterproofing materials in conjunction with moisture are known to rot burlap or cotton, and if a waterproofing material is made which resists the action of water so sulphur acids are not generated, burlap will stand up as well as anything else.

I have no desire to take issue with anyone on this, but it is obvious that there are certain waterproofing materials which are unsuitable with burlap because inherently the waterproofing materials are not adaptable. MAXIMILIAN TOCH.

New York City.

[The foregoing letter was referred to Mr. Gardiner for his comment, which follows.—EDITOR.]

Sir—Referring to the communication of Dr. Maximilian Toch, I feel flattered that I have given Dr. Toch such great news. In "Industrial Organic Chemistry," by Samuel P. Sadtler, published in 1912, we find, on pp. 307 and 308, the following statement:

"Chemically, jute differs from the bast fibers hitherto mentioned (i.e., flax and hemp) in that it contains no free cellulose but consists of a chemical compound of cellulose with lignin."

This fact Dr. Toch has overlooked and has assumed that the jute fiber contains free cellulose. It is, of course, a fact that weak alkali solutions do not attack cellulose, which is one of the main reasons why a cotton fabric, which is almost pure cellulose, is superior as a waterproofing membrane to a jute fabric. But to continue the quotation from Professor Sadtler:

"It is much more easily affected by the action of acids and alkalies than flax or hemp. The influence of air and moisture will also rot the jute fiber. It cannot be bleached safely with chloride of lime because of the readiness with which the fiber is oxidized."

Again, in the "Manual of Chemical Technology," by Rudolph von Wagner, published in 1904, we find on p. 811 the following, referring to jute:

"It is not a material adapted for purposes of nautical application as it has not sufficient firmness to withstand water."

And in J. Merritt Matthews' "Textile Fibers," on pp. 405 and 406, we find that "the chief defect of jute is its lack of durability; when exposed to dampness it rapidly deteriorates." Also, "Jute is also more sensitive to the action of chemicals in general than cotton or linen. . . . Treatment with alkalies . . . weakens and disintegrates the fiber to a considerable extent."

I might go on indefinitely with similar quotations, but when it is appreciated that we are not dealing with free cellulose at all but with a new compound with essentially different characteristics, it would seem unnecessary. The susceptibility of burlap, which is a jute fabric, to air, water and alkalies having been settled, the only question remaining is this:

Is it logical to place in the very heart of a waterproofing system and as an essential part of it a material which, it is known, will be destroyed by contact with those elements against which it is designed to give protection? J. B. W. GARDINER.

New York City.

More Light on Engineering Compensation

Sir:—Since you published my letter on engineering education and compensation on March 6 (p. 482) I have received a number of letters asking my opinion of the proper compensation to be paid to draftsmen on various classes of designs, and to surveyors, instrumentmen, chiefs of parties, and the like. This fair rate of compensation manifestly lies somewhere between what the meanest employer is willing to pay and the largest amount a man engaged in the work—and skilled in it—honestly thinks it is worth. It varies in different sections of the country and in different years. Several attempts have recently been made to fix such compensation, by engineering organizations. The recommendations I have seen are fair averages of what I am told are the rates for the most competent men in their respective classes. It is doubtful, however, that recommendations made by the employing class alone will ever be accepted as satisfactory by employees.

My letter of Mar. 6 did not discuss the actual amount of compensation paid today to employees of engineering offices. It dwelt entirely on the relation between the years of study and the expense of the education, and the very moderate salaries which large numbers of young men find to have come to them after such study and expense. There is little if anything about the study of higher mathematics, chemistry, physics, the strength of materials or the stresses in long-span bridges which fits the student of them to be better citizens, and consequently the value of the education must lie in the increased earning power of the person who completes the four-year undergraduate technical course of instruction in these and related subjects.

The information I have collected concerning the compensation of graduates of five or more years' experience in earning their living with the help of their technical studies has raised a doubt in my mind regarding the value of much of the undergraduate instruction, for many of the students. Is a four-year course of study which does not insure more than $1800 after five years and not more than $2500 after ten years necessary or even desirable, except for those whose circumstances are such that the education imposes no hardship on the family of the student? Would it not be far better to give a short, thorough course in those subjects every civil engineer must know and then, after actual experience has shown the young man in what direction he desires to acquire special knowledge, let him come back for special instruction in subjects of restricted interest necessary only to specialists?

Upper Montclair, N. J. JOHN M. GOODELL.

How Were Cost-Plus Contracts Obtained?

Sir—In your issue of Mar. 6, 1919, p. 485, is a communication from J. B. Chaffey, major, Quartermaster Corps, U. S. A., Fort Sill, Oklahoma. He descants upon the beauties of cost-plus contracts. What especially interests me he does not touch upon—that is, how to get one. I am a contractor and tried hard during the war to get a cost-plus contract, not only in construction, but also in spruce production. What I received was a polite bowing out. I could not find any way at all to break in.

I might mention that I am not at all a politician, not a Democrat, and have no pull of any kind. I have tried hard to find how to get these good things, and for the life of me can't find anyone who will point the way; so if the major will tell how these contracts can be had I would greatly appreciate it.

I was never fortunate enough to get a chance to look into the vitals of one of the cost-plus contracts, so could not criticise them, and have an idea that if I were a supervising engineer and had a friend that I wanted to see make money and be absolutely safe I would work him in, but in an ordinary contract the less "force-account" work an honest contractor has the better off he is, so I am sure the Government cost-plus is a great improvement on the usual "force-account" of civilian engineers.

There has been advanced a form of cost-plus contract in which there is competitive bidding and which extends a margin of safety, though not a limitless margin, that I wish engineers would pay more attention to—a much better plan than that adopted by the Massachusetts Highway Commission, I think. It is the sliding scale of profit and division between contractor and contractee. E. T. JOHNSON.

Portland, Ore.

[The plan of the Massachusetts Highway Commission referred to in the foregoing letter was published in *Engineering News-Record* of July 26, 1917, p. 172.—EDITOR.]

Chicago Engineers Endorse Labor Bureau Employment Service

Sir—In your issue of Feb. 13, p. 328, appeared an article by C. E. Drayer, secretary of the American Association of Engineers, attacking the activities, or lack of them, of the General Committee of Technical Societies of Chicago, more especially along the lines of employment service.

Mr. Drayer puts the case very positively; namely, that there were but two courses open to the General Committee—to get behind the employment service of either the American Association of Engineers or of the Professional and Special Section of the United States Employment Service, Department of Labor. The committee is quite in accord with Mr. Drayer to this extent. It finds that the United States Employment Service is being run with great intelligence and skill under the direction of trained engineers and technical men, giving valuable service absolutely free of charge

to all technically trained people who are out of employment, either returning soldiers or those who may be out of work for any other reason. On the other hand, they find that applicants to the employment service of the American Association, before they are registered for a position, must pay $6 and sign an application for membership in the association, and before they receive a chance for a position must pay $10 additional, or $16 total, upon election to the association. This payment is waived for a period for men in uniform.

With the above situation in mind, the committee which represents a number of technical societies and is interested in the welfare of technical men regardless of their society affiliations, decided that the free service of the United States Labor Bureau was what they should endorse and work with rather than the paid service that carried with it the propaganda of one society alone.

FREDERICK K. COPELAND,
Chairman, General Committee of
Technical Societies of Chicago.
Chicago, Ill.

Canal Seepage, Temperature and Evaporation

Sir—In the article on "Canal Seepage Losses Are Affected by Temperature," by Lynn Crandall, in *Engineering News-Record* of Feb. 13, 1919, p, 323, no mention is made of the loss of water by evaporation. The loss over the entire canal system of 2600 acres of water surface is computed from daily records of use and supply, and is called seepage. The loss thus computed is the sum of two losses: (1) That which seeps into the ground through the wetted perimeter and (2) that which is evaporated from the water surface. It is well known that the rate of evaporation from a water surface increases rapidly with increase in temperature —it may be 100% greater during July than during April. Therefore, to study the effect of temperature on the loss due to seepage, the loss due to evaporation should first be measured and eliminated. E. C. MURPHY.

Napa, Calif.

[To the foregoing letter the following reply has been received.—EDITOR.]

Sir—In reply to Mr. Murphy's inquiry regarding evaporation losses, I would say that these losses are such a small percentage of the seepage losses in irrigation canals under normal conditions that it is generally customary to consider them as part of the total loss, which for convenience is usually called "seepage."

The evaporation losses become more important in the studies of water requirements of plants where relatively large areas of moistened soil in the fields are subject to evaporation, and in reservoir storage projects, but they are of minor importance only in the study of canal losses in earth formation.

A United States Weather Bureau Class A evaporation station has been maintained at Jerome in connection with the hydrometric studies. The following are the observed amounts of evaporation in inches during the 1917 irrigation season: April, 4.23; May, 6.40; June, 9.17; July, 8.20; August, 7.03; September, 3.60; total, 38.63.

The relation between evaporation from floating pans in canals of average size and evaporation from pans on the ground, given above, varied from 65% to 72%, averaging 68%, during the irrigation season. The evaporation from the floating pans, corresponding to the 38.63 in. from the ground pan, was 26.2 in. for the season.

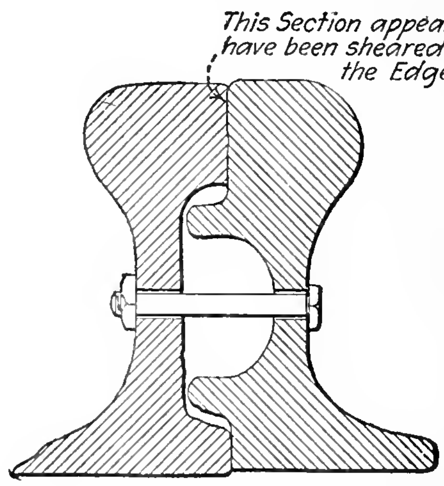
The total loss during the 1917 season due to seepage and evaporation averaged 0.70 ft. depth per day over the water surface area in the canal system, or a total for the six months' season of 128 ft. in depth. The loss due to evaporation is accordingly only 1.7% of the total loss—or, in other words, the seepage loss in three days is equivalent to the evaporation loss during the entire six months' season.

The larger loss with increasing temperature is due to the fact, not always fully appreciated, that water moves through soil more readily when warm than when cold. This has been brought out by Allen Hazen in the development of his formula on ground-water flow, and by Prof. C. S. Schlichter in Water Supply Paper No. 140 on the "Rate of Movement of Underground Waters" (United States Geological Survey).

Jerome, Idaho. LYNN CRANDALL.

More Peculiar Railroad Rail Sections

Sir—The diagram reproduced here was taken from a paper-weight which has been in the real estate office of the Baltimore & Ohio R.R., for years, and may be of interest in connection with the peculiar sections



shown in your issue of Feb. 27, 1919, p. 441. The bolt was probably put in simply to hold the parts in place.

No one here seems to know where these rail sections originally came from. W. H. McLAUCHLAN.

Baltimore, Md.

Wider Pavements Needed by Motor Vehicles at Curves

Sir—The article by G. S. Eaton on "Wider Pavements Needed by Motor Vehicles at Curves," in *Engineering News-Record* of Mar. 6, 1919, p. 461, is both interesting and exceedingly timely. It marks, I believe, a step in the direction of substituting scientific analyses of such problems for "rule-of-thumb" methods—a thing long needed in highway work.

It will be noted that the analysis as given is for the trace lines of the wheels and is of course satisfactory for single-track roads. For double-track roads, however, it should be noted that the fender clearance lines and not the wheel trace should be used. For the vehicle on the inside of the curve, this can be determined by the formula with sufficient accuracy if $R_1 + B$ is made to equal the distance from the center to the outer face of the fender, and L the distance from the center of the rear wheel to the front end of the fender. Sufficient

clearance must then be allowed to the inside wheel trace of the vehicle on the outside of the curve, and then the formula giving the radius of the outer wheel trace can be used. Some measurements of my own on a truck with a wheel-base of 13½ ft. show that, on a curve with an inside radius of 40 ft., nearly 9 in. more width is required to the fender line than to the wheel trace.

Incidentally, it might be noted that, where the quantities are odd, the trigonometric method of solving a right triangle is invariably faster and less subject to error than the "square root of the sum of the squares" method. In a case of this kind the "correction method" is even more suitable, and the formula is much simpler to use and sufficiently accurate in the form:

$$R_2 = R_1 + B + \frac{L^2}{2(R_1 + B)}$$

Gas Plant Wastes and City Water

Sir—The article by H. P. Bohmann, on "Obnoxious Tastes in Milwaukee Water" in *Engineering News-Record*, of Jan. 23, 1919, p. 181, reminds the writer of a similar experience encountered several years ago. The Quincy water-works office had always received occasional complaints regarding the water. Many of these complaints were due to sudden changes in the character of the water at the source of supply, the Mississippi River. Others were probably due to algæ growths in the storage reservoir. But in 1911 complaints of a medicinal taste in the water began to come in. Some of the persons entering complaints described the taste as being similar to that of carbolic acid; others thought it was creosote and still others mentioned iodoform and ammonia.

These complaints were not of daily occurrence. They were received at intervals of a month or six weeks. When they came, several were usually received within a few minutes, but by the time an inspector could get to the source of the complaints the trouble was practically over. It soon became evident, however, that these complaints began in the vicinity of the gas plant and followed the direction of flow of the water in the mains from the gas plant to the city limits. No complaints were received from the consumers living along the 10 blocks of mains lying between the pumping station and the gas plant.

An examination of the check valve on the 2-in. water service running into the gas works revealed the fact that something more corrosive than city water was getting through it. It was no longer a check valve, and it was very evident that gas-house liquids might be forced or drawn into the water mains at any time by the simple process of shutting off the water pressure in the district at the gas plant. Two check valves were inserted tandem in the service pipe, in 1912, and there has been no recurrence of the trouble.

At the time this trouble developed the Quincy water-supply was not sterilized. When the source of the taste was finally located, hypochlorite was being used. This would indicate that the addition of chlorine is not necessary to develop the obnoxious taste from gas-house waste.

W. R. GELSTON,
Quincy, Ill. Superintendent Water Department.

History and Use of the Manning Formula

Sir—On reading the letter by H. R. Leach and R. E. Horton on the Manning formula, in *Engineering News-Record* of Mar. 13, 1919, p. 536, it occurs to me that American engineers generally are not very familiar with that formula. Accordingly, I submit the following notes on the history and purpose of the Manning formula:

Before the publication of Parker's "Control of Water," the so-called Manning formula for open channels was not generally known to American engineers. It has, however, been used by English engineers, to some extent, in India, Australia and Egypt, during the past 20 years. It is mentioned in "Elementary Hydraulics," by Sir William Willcocks, 1899, and in Flamant's "Hydraulique," of about the same date. Buckley's "Irrigation Pocket Book" (second edition, 1913), contains an interesting discussion of the relation between Kutter's and Manning's [illegible]

It is interesting to note that the Manning formula apparently never was written by Manning in the form now used. Manning's investigation (Trans. Inst. C. E. of Ireland, Vol. XX, 1891) resulted in the derivation of an open-channel formula which has now little more than historical interest. The formula which is now used and bears Manning's name appears to be simply the result of a casual observation.

As a step in the derivation of the formula which he recommended, Manning investigated the formula $v = cr^{\frac{2}{3}} s^{\frac{1}{2}}$, and noted that the value of c (with the formula expressed in metric units) appeared to be very nearly equal to the reciprocal of Kutter's n. He did not, however, write the formula in the obvious form $v = \frac{1}{n} r^{\frac{2}{3}} s^{\frac{1}{2}}$, in which n is to be given the same value as n in Kutter's formula. This is what is now generally known as the Manning formula expressed in metric units. Expressed in English units the formula becomes,

$$v = \frac{1.486}{n} r^{\frac{2}{3}} s^{\frac{1}{2}}$$

The advantages claimed for the Manning formula are chiefly those of simplicity. Results obtained by using this formula agree very closely with those obtained with the Kutter formula, and those engineers who think of open channels in terms of Kutter's n may shift to a simpler formula without familiarizing themselves with a new set of coefficients and, it is asserted, without making any sacrifice in accuracy.

HORACE W. KING,
Professor of Hydraulic Engineering.
University of Michigan, Ann Arbor.

Water Treatment in Detroit Effective

Two pounds of liquid chlorine per 1,000,000 gal., costing Detroit 33⅓c. per 1,000,000 gal., reduced the gelatin 20-deg. bacterial count on the average from 213.7 to 10.6 per cubic centimeter. B. coli in 1 c.c. in the river water was found on six days, or 17 times in 772 tests. In 10-c.c. portions positive reactions were obtained on 178 days, or 642 times in 3860 tests. None was found in the treated water in 1-c.c. samples out of 775 tests, but in 10-c.c. samples the tests were positive on 22 days, or 23 times out of 3875 tests.

Hints for the Contractor

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Cafeteria Plan Cuts Time of Serving Meals in Camp Mess

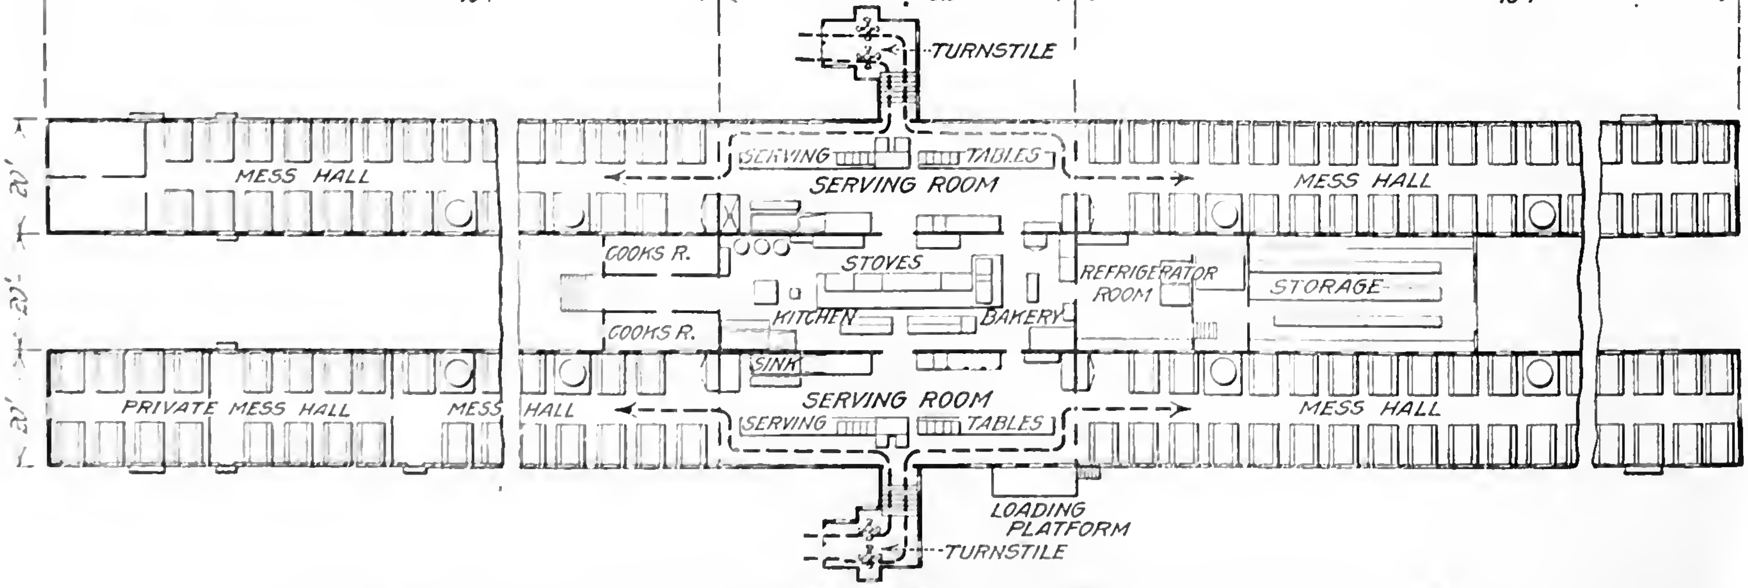
MESS-HALL arrangement and cafeteria service made possible the serving of meals in 25 min. to 1360 men constructing the extension to Camp Custer, Michigan. From Oct. 6 to Dec. 31, 1918, a total of 161,609 meals was served at a cost to the workmen of 33½c. per meal. The actual cost of each meal was 30.8c.; the remainder was profit. To accommodate the construction force, four regulation Army mess halls were connected, as shown by the drawing, using temporary construction consisting of two serving rooms and a kitchen. The meats and vegetables, when prepared, were put in copper steamers and removed from the kitchen to the steam tables, in the serving room, where they were kept hot for serving. There was one central entrance to each serving room, and the steam tables were located on either side of the two entrances. The workers passed in two lines through the turnstiles and into each serving room. At the tray and plate tables, directly opposite the entrance, the lines separated, turning to the north and south wings, and as the men passed along the steam tables they were served with meat, potatoes and two other vegetables. At the adjoining tables they received dessert, coffee, knives, forks and spoons. Then, continuing in formations, they filed into the mess halls and seated themselves at the tables. The bread and butter were served on the tables and, with this exception, it required only 25 min. for serving the food for 1360 persons, the total capacity of the four mess halls. The number of waiters depended entirely upon the number of meals served. When the noonday meals averaged 1300 daily there were two waiters stationed in each mess hall and seven at each set of serving tables, making a total of 36. During the week of Nov. 8 to 14, inclusive, when 17,859 meals were served, the mess hall force consisted of one manager, two assistant managers, two bakers, one bakers' helper, six cooks, three vegetable men, 38 waiters, seven dishwashers, four scrubmen, three laborers, one ticket seller, four checkers, three exit men and one storekeeper.

The construction of the extension to Camp Custer was under the direction of Maj. T. A. Leisen, constructing quartermaster, and Samuel A. Greeley, supervising engineer. The W. E. Wood Co., Detroit, Mich., was the general contractor. M. D. Kauffman was division engineer in charge of sanitation. In last week's issue of *Engineering News-Record*, p. 619, Mr. Kauffman told how the sanitary service rid the extension to Camp Custer of influenza.

Other Articles in This Issue of Interest to Contractors:

Saucer-Topped Garbage Table Prevents Spattering

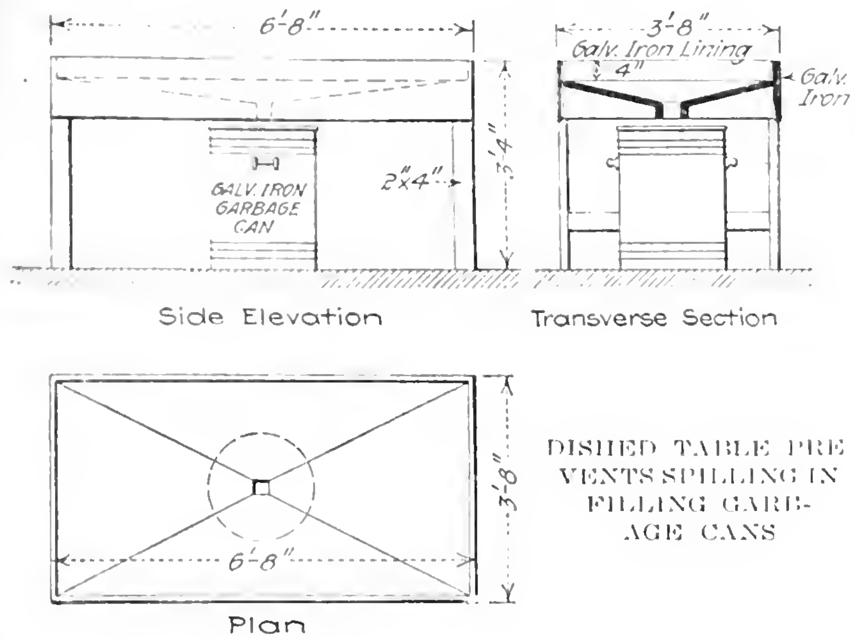
CLEANLY handling of garbage in a construction camp mess hall for the workmen building the extension to Camp Custer, Michigan, was made easy by dished tables and covered cans. The dished top of the garbage table was sheeted smoothly with galvanized iron. Through an opening in the center the garbage fell into the garbage can, which was of a height to fit closely under the table and thus prevent spattering.



FOUR MESS HALLS SUPPLIED FROM COMMON KITCHEN AND SERVING ROOMS

The dash lines indicate the lines of travel of workmen through the turnstiles, past the serving tables, to places in the mess halls

Each can held 40 gal. When filled it was covered and moved to the loading platform outside the kitchen. From here the cans were loaded into wagons designed to hold 15 cans, and were hauled to the garbage burying ground. The dished, iron-covered top of the table



DISHED TABLE PREVENTS SPILLING IN FILLING GARBAGE CANS

made washing and scouring easy, and was large and deep enough to eliminate spattering unless the kitchen help was grossly careless in the handling of the camp garbage. The names of the officials in charge of the camp are given in the preceding page, in the article describing the cafeteria plan of serving meals there.

Derrick With Drop Weight Wrecks Old Concrete Building

WRECKING a reinforced-concrete structure by means of a drop hammer, acetylene torches and cables was work required in the removal of part of the old National Guard armory in Minneapolis, Minn., in 1918. This proved a difficult task, owing to the great thickness and density of the concrete. Some of the floor slabs were nearly 2 ft. thick, and it is stated that concrete seemed to have been poured in to level up the floors in some parts. In the main hall the floor was 14 in. thick.

For breaking up the floors, a stiffleg derrick with a 20-hp. engine was installed, handling a 2600-lb. drop weight. At first an ordinary pile hammer was used as the weight, but this proved unsatisfactory, as it cut the wire strands of the cable. A pear-shaped drop was substituted, therefore, and was similar to the drop used in the wrecking of a Chicago building, as described in *Engineering News-Record* of Dec. 27, 1917, p. 1208. The Minneapolis derrick had a 40-ft. mast and a 60-ft. boom, using a drop of about 20 ft. as a rule, although at times this was increased to 40 ft. This machine was stationed first on the top story, so that it could break down the roof and then the floor, being shifted over the floor as required. It was then moved down to the lower floors, successively. Blows were concentrated at the center of the panel whenever convenient, but this plan could not be followed generally, as the work had to be done in such a manner that the vibration would not affect the remainder of the building, which has a large auditorium with the front part of the roof carried by a 160-ft. steel truss. The lower portion of this truss was connected to the slab which had to be broken down in the adjacent part of the building, so that special care was necessary to prevent damage to the truss.

Concrete girders were either broken by the drop hammer or pulled down by slings and the cable of the hoisting engine. Most of them were pulled down and then broken up on the floor by the drop weight, these blows also helping to break the floor slab. Concrete columns were pulled down and broken in the same way. An acetylene torch was used in cutting the reinforcing bars. The débris was wheeled to a chute ending in a large bin from which the wagons were loaded, the loading being done in this way in about two minutes.

Dynamite was necessary to blow up the brick arch over the main entrance, as this work was done after the derrick had been removed and hand labor was too slow. The wrecking of this part of the building and the erection of a lighter structure to replace it was done by the Cleveland Wrecking & Contracting Co., Minneapolis, Minn.

Curved Steel End Plates for Concrete Screed Prevent Waste

TO PREVENT the concrete which piles up in front of a screed on a concrete paving job from wasting over the sides as the screed is pulled back and forth, the Merrill Road Improvement Co., of Chattanooga, Tenn., has devised a curved steel plate, which is fastened to the screed, and projects out in front of it. With one of these plates at each end of the screed, the surplus concrete at the edges is dragged toward the center of the pavement each time the screed moves from side to side. Another feature is the method of operating the screed. At each end is a steel rod by which the screed is pulled back and forth, and a rope by which it is pulled forward. This arrangement is a good one for getting good screeding, as the men who pull back and forth do not pull forward, and the men who pull forward cannot push backward. This gives a steadily forward motion, and eliminates the possible backward movement which causes poor screeding. The pictures were taken on Government road work between Fort Oglethorpe, Georgia, and Chattanooga. Tenn. Maj. P. M. Ripley is constructing quartermaster, under whom W. L. Dodds is engineer in charge.

Hurley Submits a Plan for Steel Ship Operation

Would Sell Vessels at Market Price but Retain Control for a Limited Period Through Mortgage

Chairman E. N. Hurley of the United States Shipping Board announced in a speech in New York last week a proposed plan for the future control and operation of the ships which have been built under the auspices of the United States Shipping Board. Briefly, the scheme which he purposes to recommend to Congress contemplates the eventual sale of all of the Government-owned ships to private interests, but the retention of partial Government control through a period of years by means of the Government holding of a mortgage and the Government issuance of insurance. There is to be established a special fund, under the control of the Government, which will be used to foster the development of certain trade routes.

Mr. Hurley stated that when the present contracts are completed there will be under the American flag next year 16,732,700 dead-weight tons of oceangoing steel cargo and passenger ships. He is convinced that Government ownership and operation of these ships, except as a last resort, is undesirable. On the other hand, he thinks that were the ships built at Government expense to be used now merely for the advantage of groups of ship operators with sufficient capital to purchase the ships from the Government, he would unhesitatingly advocate the retention of the whole fleet by the Government. His plan is intended to provide as soon as possible the necessary development of the American merchant marine, at the same time guaranteeing to the people of the United States as large a return as possible from the war expenditure for ships.

Prices for Sale of Ships

The primary recommendation of the plan is that the ships should be sold at a price which fairly reflects the current war market for similar tonnage. Twenty-five per cent. of the purchase price of each ship is to be paid down, the remainder to be paid in annual installments over a period not exceeding 10 years. The Government will take a mortgage for this unpaid balance, charging interest at the customary commercial rate of 5%, but inasmuch as the Government ordinarily borrows money at 4%, the 1% difference will be diverted to the merchant marine development fund noted above. At the same time, the purchaser is to be re-

(*Concluded on page 690*)

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Engineering Societies Employment Bureau; secretary, 29 West 39th St., New York City.

American Association of Engineers, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Engineers' Service Bureau, maintained by the Joint Council of Engineering Societies of San Francisco, Engineers' Club, 57 Post St., San Francisco. Only applications by mail or wire will be considered.

Hold Hearing on Professional Railway Engineers' Wages

Representatives of Engineering Council and of the American Association of Engineers appeared before the Railroad Administration at Washington on Mar. 31 and Apr. 1 in reference to the proposed revised scale for the professional engineers in railway service. By restriction of a previous ruling of the administration consideration at this hearing was confined to salaries below $250 per month.

Seattle Acquires Street Railways

Transfer of the Seattle street-railway lines of the Puget Sound Light & Power Co. to the city for $15,000,000 in bonds was made Mar. 31, to become effective Apr. 1. The interest and redemption charges are to be paid from the revenues of the system. The company agrees to sell current to the city at 1c. per kilowatt until the city is ready to supply its own current. Some 2000 company employees will be put on the city payroll. Negotiations for the purchase of the Seattle & Rainier Valley Ry. are said to be well under way. The city already has some municipal street-railway lines. Thomas F. Murphine, superintendent of public utilities, announces that tickets will be eliminated and the nickel made the standard fare, except for children.

New York Engineers Move to Form Local Society

Action Taken at Meeting Called to Discuss the Engineer as a Citizen

On Mar. 26 a meeting in New York, having as its theme "The Engineer as a Citizen," resulted in the adoption of resolutions looking to the organization of a New York local engineering society, through the affiliation of existing locals and of local sections of the national engineering societies.

The meeting was held under the auspices of the New York local sections of the mining, mechanical, and automotive engineers' societies. The local members of all other societies were invited to attend and participate in the discussion. Gano Dunn presided. Philip N. Moore, of St. Louis, spoke on the civic responsibility of the engineer, Calvert Townley on his relation to legislation, Nelson P. Lewis on his relation to administration, Spencer Miller on his relation to public opinion, and Comfort A. Adams on his relation to production and distribution. In the main, the addresses followed lines already well covered in discussions of these topics. There was repeated emphasis on the need for the engineer's clear thinking in the present social crisis, while the governing idea in Mr. Miller's discussion was that the engineer's influence on public opinion would be in proportion to his spiritual strength and his character.

Except for discussions by J. E. Johnson, Jr., and G. S. Van Gilder, the remarks following the opening discussion referred to professional organization, and particularly to that of the engineers of the metropolitan district. Mr. Johnson, pointing out the function of the Engineering Council, declared that its membership was too much concentrated in New York and that it lacked the authority necessary for a strong unifying body. One of the reasons for the failure of engineering societies to rise to their responsibility, was, in his opinion, that those elected to office are men who have made reputations and do not want to risk spoiling them by turning their hands to new tasks. Lieut. Van Gilder pointed out that the responsibility of the engineer for the sociological conditions springs out of the present industrialism, which is the creation of the engineer.

Daniel L. Turner, chief engineer of the New York Public Service Commission, in the discussion of professional organization, urged the support of the American Association of Engineers as the unifying medium in civic activity.

The resolution looking to organiza-

tion of a New York local engineering society suggests that action be taken through a meeting of the secretaries of local sections and local societies, these secretaries then to call a general meeting for consideration of whatever plan may be formulated.

Resolutions were also passed calling upon all engineering societies to appoint committees on development, and upon the national engineering societies to appoint representatives to a conference committee which would draw up a simple, standard code of ethics.

The meeting was fairly well attended. Perhaps the attendance would have been larger had the notices supplied to the American Society of Civil Engineers for mailing actually been sent out to the New York members of the society.

Northwest Association of General Contractors Formed

The Northwestern Association of General Contractors was organized at a meeting held in St. Paul Mar. 26-27, at which D. A. Garber, president of the Associated General Contractors of America, and G. W. Buchholz, acting secretary, spoke on the work of the national association in its relation to local organizations. The convention was attended by about 100 of the most prominent contractors in the Northwest territory, including Omaha, Portland, Tacoma, Seattle, Duluth, Kansas City, and Grand Forks, N. D.

J. H. Ellison, of Minneapolis, spoke on "Relations of Employees and Employers," and W. L. Darling, of St. Paul, on "Unit Price Contracts." The following officers were elected: President, W. O. Winston, of Winston Bros. Co., Minneapolis; vice-president, Charles Ffolliott; second vice-presidents, A. Guthrie, of St. Paul, and Charles B. Hurley, of the Hurley-Mason Co., Tacoma; secretary, H. M. Leighton, of Minneapolis; treasurer, Claude H. Siems, of Siems, Helmers & Schaffner, of St. Paul.

Concrete Pipe Association Reorganizes

The American Concrete Pipe Assocation was reorganized by action of the annual convention, Feb. 14-15, and by further action of the executive committee, which met at Chicago Mar. 15. Greater support has been voted for the technical committee studying concrete sewer pipe, drain tile, and culvert pipe, and a series of tests has been outlined for further study of the reinforcement for culvert pipe.

There are at present, approximately, 400 manufacturers of concrete drain tile and sewer pipe in the United States and Canada, a large majority of which will be members of the association. It is planned to open offices in a short time, with executive officers in charge, to further the educational work which is now started.

T. H. MacDonald, Appointed Engineer of Federal-Aid Road Act

Thomas H. MacDonald, whose appointment as engineer in charge of work under the Federal-aid road act has been announced by the Secretary of Agriculture, was born in Colorado 37 years ago. He was educated as a civil engineer at the Iowa State College and, after a short service with the Chicago Great Western R.R., on track work, he became, in 1904, assistant professor of civil engineering in charge of road investigations at Iowa State College. Practically his entire professional career has been spent in developing the highway system of Iowa. The first legislation toward state supervision of road work in Iowa in 1906 placed this work under the supervision of the Iowa State College, and Mr. MacDonald became the executive officer at the beginning. As the work increased, an engineering as well as an administrative staff was placed under his direction, and, when the Iowa Highway Commission was created as an independent body he was naturally made the State Highway Engineer and its executive officer.

T. H. MACDONALD

The work in Iowa has been unusual, in that it is all done through the county organizations. It has required both engineering and administrative ability of a high order, and the successful manner in which the counties have been encouraged to develop sound engineering departments doubtless had a marked influence in the choosing of Mr. MacDonald to take charge of the Federal-aid work of the Bureau of Public Roads. While for the present he will devote his time more particularly to the solving of problems arising from the increased appropriations for Federal aid, it is planned that in the near future he will formally assume the position of director of the Bureau of Public Roads, made vacant by the death of Logan Waller Page. Mr. MacDonald has been active in a number of highway organizations and has been one of the influential members of the American Association of State Highway Officials.

Federal-Aid Road Bill Introduced In Canadian Parliament

A bill which would appropriate $20,000,000 to be used in aiding the provinces to build roads has been introduced in the House of Commons of the Canadian Parliament, at Ottawa. The bill provides for the payment of $80,000 per year to each province, plus a further payment based upon population as determined by the latest Federal census. It also provides that any highway for which aid is granted shall be constructed or improved in accordance with an agreement to be made with the provincial Government, covering cost and specifications. The amounts given to the provinces must not exceed 40% of the actual and necessary cost of the improvements. The sum of $25,000 was appropriated for the organization staff of the Highway Department, of which A. W. Campbell is commissioner.

Canadian Building Construction Industries Organized

A permanent organization of the Association of Canadian Building and Construction Industries, with headquarters in Ottawa, has been effected. A. S. Clarson, of Montreal, has been appointed general secretarial manager and organizer, and he will shortly visit the prinicipal Canadian cities for the purpose of establishing local branches. Mr. Clarson has had over 30 years' engineering experience, and during the past 10 years has resided in Montreal, practicing as a consulting engineer. The association, which was formed for the purpose of stabilizing Canadian construction industries, will coöperate with the national reconstruction movement inaugurated by the Government.

Interstate Flood Control Proposed

Interstate flood control through the coöperation of North and South Dakota and Minnesota is authorized so far as one of the states is concerned by a bill that has passed the North Dakota legislature and has been signed by the Governor. The bill provides for a flood-control commission, composed of the State Engineer, the dean of the School of Engineering and Mechanic Arts of the North Dakota Agricultural College, and the dean of the School of Mines of North Dakota. The commission will appoint a flood-control engineer. It is directed to coöperate with the Departments of the Interior and of War as well as with the States of South Dakota and Minnesota. Preliminary surveys of the Red River Valley, looking to flood control, are already being made by P. G. Simons, of the United States Department of Agriculture.

Hurley Submits Plan for Ship Operation

(*Concluded from page 688*)

quired to insure with an American marine insurance company his equity in the vessel, but the Government will carry in its own fund for the purchaser's account the hull and machinery insurance covering that part of the vessel for which payment has not been made. Inasmuch as the Government can carry this insurance for at least 1% less than the market rate, this 1%, too, will be diverted to the development fund.

Each purchaser who wishes to operate in foreign trade should be obliged to incorporate under a Federal charter, for which legislation will have to be obtained, and provision is to be made that all control shall remain in American hands. One member of the board of directors of each company is to be named by the Government, and these directors will be formed into a board of Government directors, who will have certain advisory powers in relation to the administration of the development fund. This fund is to be used to relieve such financial difficulties as may be encountered in the development of an adequate and well balanced American merchant marine. For instance, one suggestion is that if the Government thinks that a certain trade route should be opened, a company may buy ships for the express purpose of operating on that route. If operation does not prove profitable at once, it will be necessary to provide for the payment of defaulted interest from the merchant marine development fund in the discretion of the Government agency, and when the ships of the route earn their annual interest rate and a profit, one-half the profit earned each year should be paid into the development fund until all moneys drawn from that fund, on account of the vessel in question, shall have been replaced. The other half should go to the stockholders of the company. If the route does not prove profitable, the ships on it may be transferred by the Government to other routes and if the Government becomes convinced that the vessel has failed to make expenses solely or chiefly because of incapable management, it may foreclose the mortgage which it holds on the vessel.

A final clause in the plan is that, until sold under the terms stated, all vessels should remain the property of and should be operated by the Government of the United States. Mr. Hurley specifically stated that the wood ships are not included in this plan.

To Start Sewage-Treatment Works for Cleveland

Plans for sewage-treatment works at the westerly site, Cleveland, Ohio, will be ready Apr. 15 and bids will be received May 6. The plant will include grit chambers, two-story settling tanks, outfall conduits, buildings and appurtenances. This is the first of three proposed plants. Ed. Shattuck is commissioner of purchases and supplies, Robert Hoffmann is city engineer, and George B. Gascoigne is city sanitary engineer. The announcement of Apr. 22 as the date for opening bids made in our advertising columns of earlier date was due to a misunderstanding.

New Assistant Secretary for Civil Engineers' Society

The March *Proceedings* of the American Society of Civil Engineers announces the appointment of Capt. Stephen L. Coles as assistant secretary, succeeding Thomas J. McMinn, who for 21 years has been assistant secretary of the society. Mr. McMinn will continue to give the society the benefit of his experience in the society's work until Captain Coles becomes familiar with his new duties, after which the former will be retired on half pay.

Captain Coles has been identified chiefly with electrical engineering work, having made a special study of service and public-policy questions affecting central electric-light stations. After leaving the Massachusetts Institute of Technology he became Boston correspondent and later managing editor of the *Electrical Review*. He has written extensively on electrical subjects, both for the lay and engineering press, was at one time acting secretary-treasurer of the Society for Electrical Development, aided the Toronto Electric Light Co., Ltd., of Toronto, Can., in working out its general policies, and just before entering the Ordnance Department of the Army, during the war, was on the engineering staff of M. W. Thompson, specialist in litigated engineering matters and in reports on railroads and other large properties. In this work Captain Coles devoted his attention principally to electrical public utilities having problems of service, policy, and competition to solve.

Captain Coles is not a member of the society.

National Lumber Manufacturers to Hold Convention

The National Lumber Manufacturers' Association will hold its annual convention Apr. 16-17, at the Congress Hotel, Chicago. Most of the sessions will be devoted to a discussion of subjects which more particularly pertain to the industry, but on the morning of Apr. 15 a technical session will be held at which the following subjects of interest to engineers will be presented:

"Standards of Wood Construction from the Standpoint of the Architect," by Sullivan W. Jones, chairman of the Structural Service Committee, American Institute of Architects; "Commercial Uses of Treated Lumber," by A. R. Joyce, acting president of the American Wood Preservers' Association; "Development in Heavy Timber Construction," by C. E. Paul, construction engineer, National Lumber Manufacturers' Association; "Protection from Fire in Wooden Buildings," by W. C. Robinson, vice-president and chief engineer of the Underwriters' Laboratories.

Two-Day Technical Meeting of Water Producers

Purification and Other Topics Occupy Attention of Illinois Section of Water-Works Association

Practically all of the twenty papers presented Mar. 25-26 at the well attended meeting of the Illinois Section of the American Water-Works Association were technical. Chemical treatment for the softening, clarification and sterilization of water was treated in five papers. Well supplies, pumping, construction and operation received attention in three papers. War work was reflected in an equal number.

M. F. Stein reviewed the work of the testing station at Cleveland, Ohio, on water softening. The design of the chemical treatment process as dictated by the experimental work was brought out to indicate that local tests should precede design in most cases.

Several typhoid fever outbreaks in Moline, Ill., have occurred in the past two years. M. C. Sjoblom traced the cause to a bypass valve permitting unfiltered water to enter the clear well at a time when little or no chlorine was being applied.

Lieut. Everett Judson, of the United States Public Health Service, detailed experiments on adonite, a fermenting sugar, to differentiate B. coli. Opinions expressed in discussion indicated that the test was not yet a safe one.

Chlorine, Chloramine and Crenothrix

After a trial of more than a year the Champaign & Urbana Water Co. still finds the use of 4.6 lb. of chlorine per 1,000,000 gal. is an effective agent in eliminating crenothrix from its ground water-supply, said F. C. Amsbary. W. F. Monfort, in detailing work done on the problem in conjunction with O. A. Barnes, indicated that chloramine was a better reagent, but that the difficulties of its application and in preserving its stability made the chlorine more desirable so long as it continued to kill the crenothrix.

Minna E. Jewell has been making intensive studies of the Sangamon River, one of the most polluted streams of the state. Her findings indicate that biological tests are perhaps more practical than chemical or bacterial in determining the extent to which stream pollution may be permitted without the creation of a nuisance.

Experience with the new large-capacity 36-in. well at the University of Illinois was described by Prof. M. L. Enger. Unlike the smaller wells, its capacity per foot of draw-down has increased in two years from 19.5 to 21.5 gal. per minute. One of the older wells was reduced in 10 years from 7.2 to 4.9 gallons.

Consumption of water at Illinois state institutions varies from 70 to 350 gal. per capita per day, said F. J. Postel. Meters are installed on the low-consumption systems. Deliberate waste of water through compression

cocks in the reform school where the boys balanced the valves open so as to wash in running water is being stopped by arranging the cocks with a stop which prevents opening them wide. So serious was the water shortage in Jacksonville in the winter of 1918 that snow was thrown into the reservoirs and even brought in to the bath tubs. Wells are always provided at state institutions because of their desirability if there is any chance of an adequate supply being found.

UNUSUAL WELL-WATER SUPPLY AT BATON ROUGE

L. R. Howson outlined the unusual well-water supply conditions of Baton Rouge, La., where 2050-ft. wells deliver water at a temperature of 92° F. with a static head of 120 ft. One well sunk in 1916 discharged for 6 hours at night directly into the city mains, delivering at a 300,000-gal. rate and maintaining a pressure of 30 lb. The practice has recently been discontinued on account of additional pressure required for automatic sprinklers. There are 14 separate sand strata bearing water of different character. Through the fine sand of Louisiana water at 92° is transmitted 1⅔ times as rapidly as through a similar sand with a temperature of 50 degrees.

The Old Hickory Powder Works water-supply was described by O. E. Bulkeley. Ninety-six tub gravity filters with a daily capacity of 65,000,000 gal. were hand-operated. Determination of the rate by noting the drop each hour, and the satisfactory utilization of women as filter attendants, were features of the operation.

The officers chosen for the coming year are: Chairman, W. E. Lautz; vice-chairman, F. C. Amsbary; treasurer, H. E. Keeler; secretary, G. C. Habermeyer, Urbana.

Augusta, Ga., Flood-Protection Work Completed

Flood-protection levees at Augusta, Ga., started in 1909, were recently completed, according to a report by Nisbet Wingfield, city engineer, who has also been chief engineer of the river and canal commission which has had charge of the protection work. This whole system was described in *Engineering News* of Aug. 6, 1914, p. 277. It comprises an 11-mile earth levee with reinforced-concrete bulkhead gates at intervals from a point just above the city, three miles through the city, to a point eight miles below. It was started after the disastrous flood of 1908. Flood tide on Dec. 24, 1918, reached a height which under the old conditions would have overrun a large part of the city, but, due to the effectiveness of the protection, no damage was caused, except the shut down of power plants for a few days, owing to the shutting off of their connecting water-supply. The total cost of the work ran above $2,000,000.

Providence Water-Supply Project Goes Forward

Construction work on the new gravity water-supply for Providence, R. I., is going forward immediately, according to present plans. Bids for 5.2 miles of road work as a part of the Scituate reservoir road relocation will be received Apr. 9, and it is expected that further bids will be invited later in April. In the late summer, or early autumn, if conditions then are favorable, bids will be asked for the main dam and dike. This will involve about 2,500,000 cu.yd. of earth, besides gate chambers, masonry spillway and a reinforced-concrete bridge. Some preliminary work on the project has already been done. Frank E. Winsor is chief engineer of the Water-Supply Board.

Heavy Reduction in Lowest Bid Compared with Last August

Bids for furnishing and laying 34,590 ft. of 72-in. riveted steel pipe line to duplicate the portion of the Jersey City water-supply conduit from the Boonton reservoir to the Watchung tunnel were opened on Mar. 25. They were 15 in number. The range was from $1,098,076 to $1,783,977. The lowest bid for the same work on Aug. 13, 1918, was $1,578,921, showing a reduction of $480,845. The award was not made last year because the Priorities Board withheld its approval of the use of steel plate at that time. Clyde Potts, New York City, is consulting engineer for the work and Michael I. Fagen is director of the Department of Streets and Public Improvements of Jersey City.

Civil Service Examinations

For United States Civil Service examinations listed below, apply to United States Civil Service Commission, Washington, D. C., or to any local office of the commission, for form 1312.

United States.—Engineer-draftsman, Apr. 22, $1500 to $1800 per year. File application before Apr. 22.

United States.—Transitman, $100 to $125 per month, and surveyor, $125 to $200 per month, Apr. 23-24. File applications in time to arrange for examination at place selected by applicant.

United States.—Expert patent investigator, $1800 to $2400 per year, and technical patent expert, $2400 to $3600 per year, May. 20.

United States. — Assistant material engineer, Bureau of Construction and Repair, from $4.48 to $6.40 and upwards per diem. No date specified. Applications should be filed without delay.

United States.—Statistician, Department of Interior, $1800 per year, May 13. Apply for Form 2118.

United States.—Junior recreational engineer, Forest Service, Denver, Colo., $1800 to $2400 per year, May 6. Apply for Form 2118.

ENGINEERING SOCIETIES

Calendar

Annual Meetings

NATIONAL FIRE PROTECTION ASSOCIATION; 87 Milk St., Boston, Mass.; May 6-8, Ottawa, Can.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

AMERICAN SOCIETY OF CIVIL ENGINEERS; 29 W. 39th St., New York; June 17-20, St. Paul-Minneapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS; University of Pennsylvania, Philadelphia; June 24-27, Atlantic City.

The Engineers' Club of Philadelphia was addressed at the weekly luncheon Apr. 1 by Col. W. B. Ladue, Corps of Engineers, U. S. district engineer at Philadelphia, on "Harbor Developments for the Port of Philadelphia." Dr. Henry Leffman will read a paper on "The Truth About Whisky" at the weekly luncheon Apr. 8.

The Montreal Branch of the Engineering Institute of Canada will be addressed Apr. 3 by V. I. Smart, who will speak on the "Operation of Railways as an Engineering Problem." At the meeting Apr. 10 J. A. DeCew will present a paper on "Waterproof Paper Productions and Their Industrial Possibilities."

The Architects' and Engineers' Club, Ann Arbor, Mich., is the name adopted for the new organization formed at a meeting of the engineers and architects of Ann Arbor Mar. 25, at which the object of organization was stated to be "the promotion of the social, economic, and technical interests of its members, and civic activity and public service." The club has 72 members. A committee was appointed to follow pending legislation in the state legislature concerning the regulation of public utilities, and it was instructed to exert the influence of the club for proper recognition of the engineering profession.

The Texas Association of Members of the American Society of Civil Engineers will hold its semi-annual meeting at San Antonio Apr. 25-26. R. J. Potts of Waco is president of the association and J. H. Brillhart of Dallas is secretary.

The Ottawa Branch of the Engineering Institute of Canada on Mar. 20 held its first meeting since the annual general meeting. Lieutenant Commander Edwards, superintendent of the Canadian Radio-Telegraph Service, provided a series of interesting experiments to illustrate the sending and receiving of electric waves, the meeting

being held in the testing room of the Canadian Naval Radio Telephony Service. Each member of the audience was provided with a telephone receiver and was enabled to listen to some of the high-power sending stations. The second meeting of the branch was held Mar. 27 to discuss the subject of proposed provincial legislation defining the status of engineers throughout Canada.

The Engineers' Club of St. Louis held a meeting Apr. 2, devoted to a discussion on the prospectus for a conference of engineering societies, to be held in Chicago Apr. 23-25, on the establishment of a Department of Public Works.

The Associated Engineering Societies of Seattle and the Engineers' Club of Seattle held a joint meeting Mar. 21 at which George F. Nicholson, chief engineer of the port of Seattle, presented a paper on "Port of Seattle Engineering Problems," illustrated with motion pictures of port operation along the Atlantic coast.

The Engineers' Club of Seattle was addressed Mar. 20 by Lloyd Robey on "The Chuquicamato Mine of Chile," of which he is assistant superintendent.

The Indiana Sanitary and Water Supply Association will hold its annual meeting in Indianapolis Apr. 9-10.

The American Welding Society, the formation of which was noted in *Engineering News-Record* of Mar. 13, p 545, held its first meeting Mar. 28 in New York City. The constitution and bylaws recommended by the organization committee were adopted, and the following officers were elected: President, C. A. Adams, Cambridge, Mass.; secretary, H. C. Forbes, 33 W. 39th St., New York City.

The Cornell Society of Civil Engineers will hold its spring meeting Apr. 14, at the United Engineering Societies' Building, New York City. Prof. C. R. Mann will speak on engineering education, and the proposed combination of Sibley College and the College of Civil Engineering will be discussed. It is expected that this will be a joint meeting of the recently organized association of Sibley men and the Cornell Society of Civil Engineers.

The Engineers' Club of Trenton, N. J., was addressed Mar. 27 by R. J. Wig, chief of the concrete ship section, Emergency Fleet Corporation, who presented a paper on "The Present Status of the Concrete Ship," illustrated with slides.

The Rochester Society of Technical Draftsmen was addressed Mar. 27 by Frank C. Taylor of the Rochester Railway & Light Co., who spoke on "Illumination."

The Oregon Society of Engineers held a smoker in Portland Mar. 21, at which various members and guests spoke on the subject of the compensation of engineers, although no prepared addresses had been planned. There was a general discussion of the advisability of organizing engineers for the purpose of obtaining higher rates of pay.

The Oregon Association of Members of the American Society of Civil Engineers held a meeting in Portland Mar. 20 at which Robert A. Cummins, consulting engineer and contractor of Pittsburgh, member of the Committee on Development, spoke on the work of the committee. Mr. Cummins was in Portland serving with a board of four other engineers, studying the subsidence of the Portland municipal grain elevator on the Willamette River.

The Rochester, N. Y., Engineering Society will hold its regular monthly meeting Apr. 11. George Halcott Chadwick, assistant professor of geology, University of Rochester, spoke on "What is Under Rochester" at the weekly luncheon Mar. 31.

The Pittsburgh Chapter of the American Association of Engineers will be addressed Apr. 17 by C. E. Drayer, national secretary. The chapter has taken headquarters in the Fulton Building; they are in charge of F. E. N. Thatcher, secretary.

The Civil Engineers' Club of the Carnegie Institute of Technology, Pittsburgh, was recently addressed by C. K. Harvey, of the Koppers Co., who spoke on "Civil Engineering Work in Byproduct Coke Plants."

Personal Notes

CAPT. LITTELL SNIVELY, Engineers, U. S . A., has received his discharge from the service and has become mine engineer, Guanajuato Consolidated Mining & Milling Co., Guanajuato, Mexico.

WILLIAM C. HALE, assistant chief engineer, Rust Engineering Co., Pittsburgh, has resigned to become chief engineer of the Andrews Engineering Co., also of Pittsburgh.

ALBERT LADD COLBY, consulting engineer and iron and steel metallurgist, South Bethlehem, Penn., has been appointed representative of the American Society for Testing Materials on the Engineering Council.

CAPT. ELWOOD AVERY, Construction Division, U. S. A., has received his discharge from the service and has become associated with G. W. Ensign, Inc., engineers and contractors, Harrisburg, Penn., as chief engineer.

E. L. MARTIN, engineer maintenance of way, Missouri, Kansas & Texas R.R. and associated railroads, has been appointed chief engineer with jurisdiction over the Missouri, Kansas and Texas Lines of Texas and the Missouri, Kansas & Texas R.R. He was born in 1879 and received his education at the Agricultural and Mechanical College of Texas. He entered the service of the Southern Pacific Lines in 1899, becoming assistant engineer three years later. He afterward became connected with the Kansas City Southern and later became division engineer for the Gulf Coast & Santa Fé Railway in Texas. Afterward he served as assistant superintendent for the Southern Pacific at Lafayette, La. In 1913 he became division engineer for the Missouri, Kansas & Texas, and was appointed engineer maintenance of way in 1917.

CAPT. A. L. MULLERGREN, Construction Division, U. S. A., having been discharged from the service, has returned to his work as secretary and treasurer of the Benham Engineering Co., consulting engineers, Oklahoma City, Okla. Captain Mullergren was officer in charge of steam heating and assistant to the constructing quartermaster at Camp Funston, Kansas.

C. H. PURCELL has been appointed bridge engineer for the Oregon State Highway Commission, assuming office Apr. 1. Several years ago Mr. Purcell served as bridge engineer for the commission, when H. L. Bowlby was its chief engineer. Later he was bridge engineer for two years in the Multnomah County engineer's office, after which he returned to the Highway Commission as bridge engineer and assistant chief engineer. More recently he has been attached to the Portland office of the Department of Roads and Rural Engineering.

LIEUT. HARRY B. FRIEDMAN, Air Service, U. S. A., who received his discharge in January and entered the service of the W. E. Wood Co., general contractors, Detroit, as engineer and representative in Fort Worth, Tex., has resigned to enter into a partnership with Butcher & Sweeney, general contractors, Fort Worth.

LIEUT. C. E. PRETZ, Engineers, U. S. A., has received his discharge from the service and resumed his work with the Public Service Commission, with headquarters in New York City.

CAPT. H. RAY KINGSLEY, Engineers, U. S. A., who received his discharge from the service in February, is now engaged in his former work as building engineer for the insular government, Bureau of Public Works, Manila, P. I. In 1916 he went to France on leave from the insular service and enlisted in the American Ambulance Corps of the French Army, where he served for three months, afterward returning to the United States on his way to the Philippines, where he was commissioned in the Engineers in October, 1917.

MAJ. WALTER B. ELCOCK, U. S. A., has been discharged from the service and has returned to his work as manager of the Atlanta office of the Portland Cement Association.

LIEUT. COL. W. M. DENMAN, Engineers, U. S. A., has been discharged from the Army in France and has become a member of a company known as "Société d'Importations Américaines," with office at 57 Rue de

l'Université, Paris-7e. The new organization, as its name indicates, will engage in importing American products into France. Colonel Denman's home is in Springfield, Mass.

MAJ. JAMES H. BRACE, 22nd Engineers, a light-railway regiment who recently returned from France, has been discharged from the Army and has resumed his work as vice-president of Fraser, Brace & Co., contractors, New York City.

LEWIS R. ASH of Harrington, Howard & Ash, consulting engineers, Kansas City, has tendered his resignation as city manager of Wichita, Kan.

GEORGE WORTH, formerly associated with the Sager Lock Co., North Chicago, has been appointed chief engineer of the city water works of Waukegan, Ill.

ADOLPH F. MEYER, chief engineer and general superintendent, Minnesota & Ontario Paper Co., International Falls, Minn., has resigned and will resume private practice, specializing in hydraulic, structural and paper-mill engineering, with headquarters in St. Paul or Minneapolis.

MAJ. ERNEST MCCULLOUGH, of the Chemical Warfare Service, formerly consulting engineer of Chicago, Ill., has been made lieutenant colonel. He is still in France.

COL. FRANCIS F. LONGLEY, Engineers, American Expeditionary Forces, in charge of water-supply in the advance and rear sections, has been detailed to go to London and take charge of Army educational work at English universities. Before entering the Army he was a member of the firm of Hazen, Whipple & Fuller, New York City.

MAJ. J. C. SMITH, American Expeditionary Forces, who recently returned to this country, has received his discharge and has become office engineer, Northwestern Region, United States Railroad Administration, with headquarters in Chicago. He was formerly in the service of the Spokane, Portland & Seattle Railroad.

W. E. BECKER and C. R. SMYTH have become associated under the firm name of Becker & Smyth, contracting engineers, Chicago.

MAJ. G. T. LEMMON, Engineers, U. S. A., who received his discharge from the service in January, has become resident engineer of the Virginia State Highway Commission, with headquarters at Suffield. He entered the service as a first lieutenant of engineers in July, 1917.

CHARLES WUEST, JR., formerly engineer of roads, United States Nitrate Plant No. 4, has been appointed office engineer, Division of Highways, Illinois Department of Public Works and Buildings, with headquarters in Springfield.

MAJ. CARLISLE MASON, American Expeditionary Forces, having returned from France and received his discharge from the service, will resume the practice of general consulting engineering, with main office at 207 Broadway, New York City, and branch office at 81 Rue St. Lazare, Paris, France.

A. E. TRIPLEGG, district engineer of the Missouri, Kansas & Texas R. R. of Texas, has been appointed engineer maintenance of way, with headquarters at Dallas.

H. R. CARTER, state highway engineer of Arkansas, has resigned to engage in private practice.

BRIG. GEN. B. P. DISQUE, chief of the Spruce Production Division, U. S. A., has been appointed to the chairmanship of the export and import branch of the American International Corporation, New York City, having received his discharge from the service Mar. 15. He is succeeded as president of the Spruce Production Corporation and commander of the first division by his former chief of staff, Lieut. Col. C. P. Stearns.

CAPT. M. Z. BAIR, Construction Division, U. S. A., has resumed his duties in the division of sanitary engineering, Ohio State Department of Health, having received his discharge from the Army.

CHARLES H. HURD, consulting engineer, Indianapolis, has resigned from the Board of Sanitary Commissioners and will devote his entire time to private practice. Lucius B. Swift, member of the bar of Indiana, has been appointed a member of the commission.

CAPT. ALVAH G. HUSTED, Sanitary Corps, U. S. A., will resume his work with the Indianapolis Sanitary Commission, having left the Army.

CAPT. S. M. SMITH, Engineers, U. S. A., recently returned from overseas, has received his discharge from the service and has returned to the office of the chief engineer, Wabash Ry., as principal assistant engineer. In France Captain Smith was engaged in the development of the canvas portable-type foot bridge, which met with success in the battle of the Meuse during the week previous to the armistice.

F. RAYMOND KEYS has left the service of the Bureau of Yards and Docks, U. S. N., with which he was associated during the war, and has become connected with the Nugent Construction Co., New York City.

CAPT. JOHN W. TOYNE, Utilities Officer, Camps Chickamauga Park and Fort Oglethorpe, Georgia, has received his discharge from the service and will resume the private practice of engineering at South Bend, Ind.

D. J. CAMERON, who recently received his discharge from the Engineers, U. S. A., has been appointed to take charge of the northern New Jersey territory of the Fireproof Products Co., Inc., New York City, with headquarters in Newark.

H. H. JOHNTZ, division engineer, Missouri, Kansas & Texas R.R. at Parsons, Kan., has been appointed engineer maintenance of way of the Missouri, Kansas & Texas R.R. and the Oklahoma Belt, with headquarters at Parsons.

OSCAR F. LACKEY and LYMAN L. LIVINGSTON have become associated under the firm name of Lackey and Livingston, consulting engineers, 17 Battery Place, New York City.

W. H. VANCE, engineer maintenance of way, St. Louis-Southwestern and Louisiana & Arkansas Rys., has been appointed engineer maintenance of way, St. Louis, Southwestern and Associated Lines, including the St. Louis Southwestern of Texas, the Eastern Texas, Dallas Terminal & Union Depot, and the Southern Illinois and Missouri Bridge R.R., with headquarters at Tyler, Tex.

OBITUARY

MAJ. JAMES ALFRED ROOSEVELT, U. S. A., previously general superintendent of the Third Avenue R.R., New York City, died Mar. 26 on the naval transport Great Northern, on its way to the United States. He was born in 1885 and was graduated from Harvard University in 1905, soon afterward forming the engineering firm of Roosevelt & Thompson, New York City. In 1907 he became general superintendent of the Third Avenue R.R. Four years later he was appointed to direct the system of street-railway and interurban lines of the British Columbia Co., with headquarters in Vancouver, B. C. He received the commission of captain early in 1917 and was assigned to the 308th Infantry. He was in much of the heavy fighting with the 77th Division.

CAPT. STUART THOMSON, Ordnance Dept., U. S. A., died in Brookline, Mass., Mar. 23. He was graduated from Harvard University in 1908 and from the Massachusetts Institute of Technology in 1909. He had recently returned from Washington, where he had been engaged in the production of aircraft armament for the past year and a half.

CAPT. ARLY L. HEDRICK, Engineers, American Expeditionary Forces, died recently in Brest, France. He received his education at Yale University and the University of Wisconsin.

AUGUSTUS W. NEWELL, railway and mining engineer, died at his home in Bradford, Penn., Mar. 25. He was born in 1832 and did his first work on the Brookline reservoir and later was employed by the Boston & Maine R.R. He was also engaged in the location of the Charles River R.R. and the "Air Line" of eastern Massachusetts. In 1856 he became associated with the Buffalo, Bradford & Pittsburgh R.R., becoming a director of the line in 1863. After that time he engaged in mining operations and assisted in the development of the Bradford oil fields.

Tractor Output for 1918-19

A total of 132,697 tractors was manufactured in 1918, and it is estimated that 314,936 will be manufactured in 1919, according to a report of the United States Department of Agriculture based upon inquiry made among manufacturers. The figures for 1919 are of course merely estimates, and represent the aggregate of the estimates submitted by the tractor manufacturers in January and February of this year.

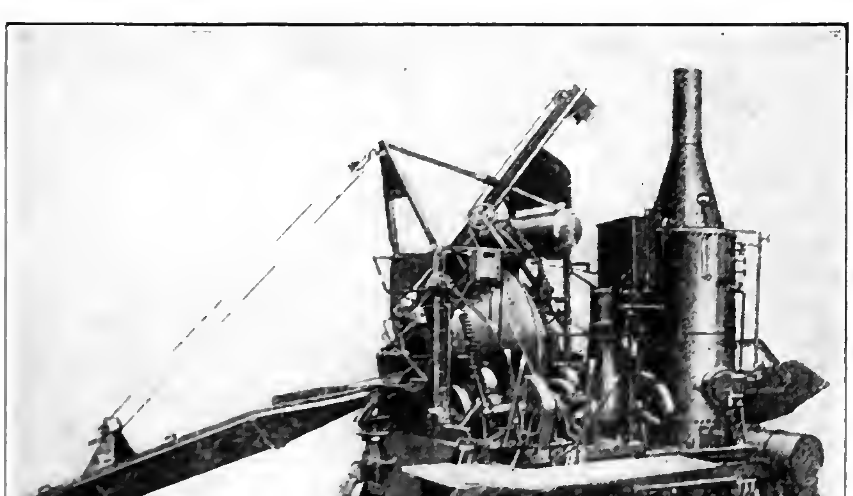
Construction Machinery Exports

An indication of the extent of American export trade in construction machinery is contained in the reports of the Bureau of Foreign and Domestic Commerce of the Department of Commerce, Washington, D. C., for January. Two of the items are: Pumps and pumping machinery, $572,445; excavating machinery, $26,627.

New Paving Mixer Propelled by Multiple-Tread Apparatus

A concrete paving mixer with track-laying propulsion is shown in the accompanying illustration. It is intended to obviate the necessity of using planking over subgrade too soft to bear the load of the ordinary wheel-propelled outfit. The machine is also equipped with a batch-timing device which locks the discharge trough, so that each batch must be mixed until any fixed time previously determined and set in the timer has been completed.

The treads are 9 ft. long and 14 in. wide, which, with the 18,000 lb. weight carried, gives a ground pressure per square inch less than that of the average walking man. The treads are driven independently of one another through friction clutches, which permits the turning of the machine in its own length.



PAVING MIXER EQUIPPED WITH MULTIPLE-TREAD PROPULSION

Other advantages claimed are: A large saving in cost, due to the elimination of planking and the delays incident to its use; noninjury to the finished subgrade, and ability to operate where machines of the old type cannot go.

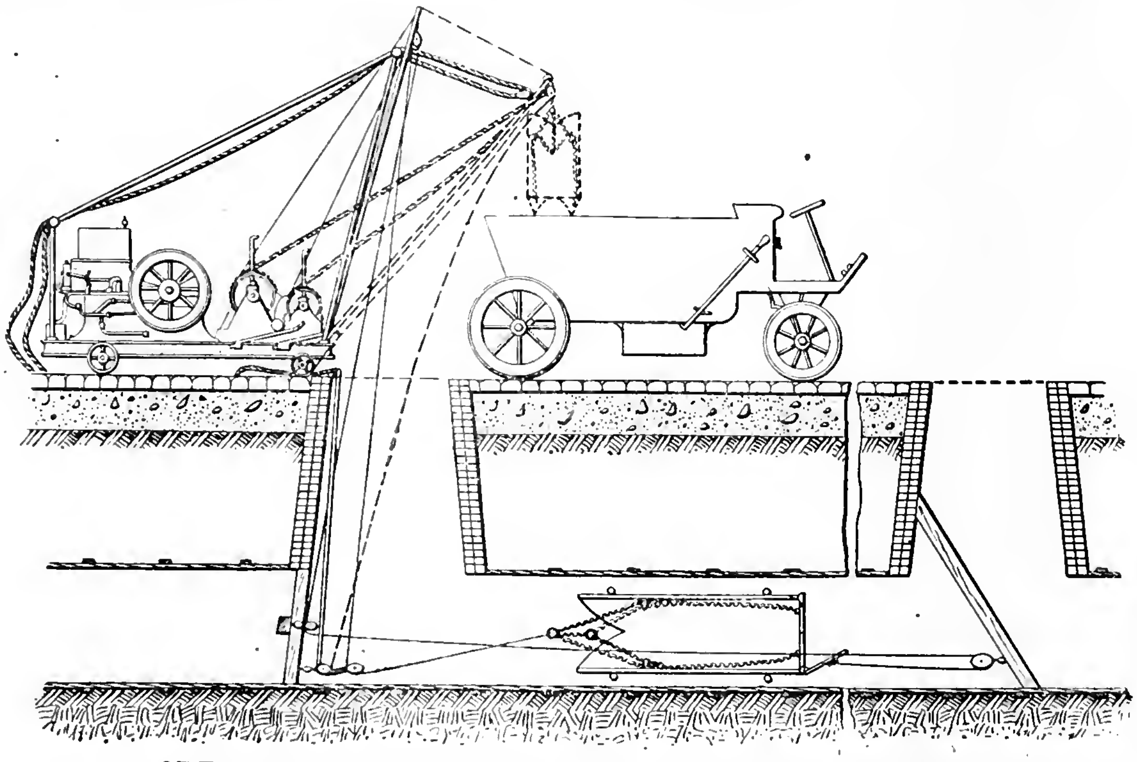
The machine illustrated is manufactured by the Foote Co., Inc., Nunda, N. Y., and these treads are put on both sizes of its paving mixers. Application has been made for a copyright on the trade name "Multi-Foote" for the tread.

Sewer Cleaner is Operated by Crew Above Ground

Elimination of the necessity for a sewer-cleaning crew to work in the water and poison gas of the sewer chamber is the purpose of a device invented and patented by P. J. Healey, contractor, of 30 Church St., New York City. Cables and pulleys are arranged so that a small pipe derrick with a gasoline engine may drag a digging bucket back and forth through the sewer and then hoist it to the street level, while the whole crew remains above ground.

It is necessary to place a timber in each manhole to hold the pulleys. The cables pass down the near manhole, and change direction on blocks, and are fastened to either end of the bucket, the line to the bottom of the digging bucket passing around the block in the far manhole. To make it possible to lift the bucket from the sewer, the direct line block at the near manhole is attached to the end of a rope passing through another block which is secured to the timber. When the bucket is pulled up, the first block comes up with it, pulling the rope through the second block. By pulling in and fastening the rope as the bucket is lowered, the outfit is again prepared for digging.

The bucket has a double shovel-shaped nose and a two-leaf dump bottom, as illustrated. In order to facilitate travel through the sewer, small casters have been placed on its sides. Digging is a scraping process, the bucket being dragged back and forth, loosening and collecting the spoil, until full. It is stated that members of the crew are required to work in the sewers only when placing the timbers which hold the pulleys.



OPERATION OF IMPROVED SEWER-CLEANING MACHINE

Business Notes

The Berger Mfg. Co., sheet steel products, New York City, announces that it has moved its office from 154 Eleventh Ave. to 516-524 West 25th St., New York City.

The New Way Motor Co., Lansing, Mich., manufacturer of air-cooled gas engines, announces the appointment of Harry J. Sproat as secretary and factory manager.

The Flower-Stephens Mfg. Co., Detroit, manufacturing valves and hydrants under the trade name "Michigan," is now to be known as the Flower Valve Manufacturing Co.

The Eastern branch of the Independent Pneumatic Tool Co. in New York City, has been moved from 170 Broadway to 1463 Broadway. The company's pneumatic and electric tools and gasoline engines are sold under the trade name "Thor."

The excavation machinery manufactured by the Pawling & Harnischfeger Co. is to be handled by the following newly appointed agents: the W. E. Austin Machinery Co., Atlanta, Ga.; the Henry H. Meyer Co., Baltimore, Md.; Edlen & Co., Philadelphia, Penn.; Charles J. McCarty, Boston, Mass.; the W. W. Williams Co., Columbus, Ohio; the W. B. Louer Co., Chicago,

Ill.; the H. W. Moore Co., Denver, Colo.; W. H. Zeigler, Minneapolis, Minn., and Gaston, Williams & Wigmore, Inc., New York City. The last named firm is an expoiting agent.

H. A. Frank, managing director of the Nova Scotia Shipbuilding & Transportation Co., Ltd., Liverpool, N. S., has also recently been made managing director of the Mirimachi Construction Co., Ltd. The new company has taken over the assets of the International Shipbuilding Co., Ltd., Newcastle, N. B., consisting of yard, plant, machinery, stock of material and a vessel framed on the stocks. Operations will begin immediately for the completion of this boat, and the same company will also construct a small vessel of about 150 tons net register.

The Poston Paving Brick Co., of Crawfordsville, Ind., one plant, and the Burton-Townsend Co., of Zanesville, Ohio, two plants at Zanesville and one plant at Ashtabula, Ohio, have become licensees of the Dunn Wire-Cut Lug Brick Co., of Conneaut, Ohio, and will engage in the manufacture of wire-cut lug paving brick.

The Carson Petroleum Co., 208 So. La Salle St., Chicago, Ill., announces that George Fuchs, formerly of the Texas Co., asphalt sales department, has been appointed Southern representative of the asphalt and road-oil sales department of the Carson Co., with headquarters at Tampa, Fla.

The W. A. Jones Foundry & Machine Co., of Chicago, manufacturer of power-transmission apparatus, special foundry and machine work, together with the Jones spur gear speed reducer, has opened an Eastern office at 30 Church St., New York. Lemuel C. Biglow, formerly with the Morse Chain Co., of Ithaca, N. Y., is in charge of the New York office.

The Epping-Carpenter Pump Co. announces the appointment of F. S. Healey as manager of sales, in addition to his former office of chief engineer. He will replace F. F. Woods, who is now located in New York as Eastern sales manager. Other appointments are those of Albert A. Scheuch of the sales department as assistant sales manager, and Paul D. Goodman, formerly of the McClary-Jemison Machinery Co., of Birmingham, Ala., to the sales department.

The United Gas Improvement Co., Philadelphia, Penn., announces the formation of another department, to be known as the U. G. I. Contracting Co. The new organization, besides handling the construction and sale of water-gas apparatus, vertical retorts, etc., will design and erect power plants and will maintain a special road division competent to construct and maintain roads. Paul Thompson, one of the vice-presidents of the parent company, will have charge of the new organization. The other officers are J. A. P. Criffield, vice-president, for engineering; D. J. Collins, vice-president, for sales.

Construction Costs Stabilizing—Material and Labor Markets

Only General Decline Was in Steel—Labor Conditions Shown in Many Sections—Stagnation in the Building Trades

By Alden W. Welch

Common Labor

The impression seems to be quite general that there is a heavy surplus of common labor. It is true that in certain sections — particularly on the Pacific Coast — labor is plentiful, but this condition does not prevail throughout the country. It might be expected that at a great port of debarkation, such as New York City, common labor would be a drug on the market. Yet the reverse is the case, according to the Building Trades Employers' Association of this city. In spite of the homecoming soldiers, common labor is not over-plentiful and the wages are high. Pick and shovel men are paid $3.50 to $4 per eight-hour day; semi-skilled laborers, $4 to $4.50.

On the Pacific Coast

The unstable condition created by the Government in acceding to the shipyard laborers' demand for higher wages is noticeable on the Coast, as elsewhere. The rate of shipyards under the Macy award is $4.16 per eight-hour day; while at Government-owned yards $4.64 is paid. This unbalance exists in San Francisco, at the Puget Sound Navy Yard at Bremerton, Wash., and in the privately owned plants in the same district; and at San Pedro, in southern California.

For unorganized or nonunion labor the wages paid all along the Western coast are $3.50 to $4 a day. It is reported that the City of Oakland has just advertised a civil-service examination for laborers, offering wages of $3.50 per day.

Unskilled labor out of employment in the larger cities of California is estimated at from 20,000 to 25,000.

In Portland, Ore., the unemployed are estimated at 10,000 to 12,000; in Seattle and Tacoma, Wash., at about the same figure. Before the armistice was signed it was almost impossible to obtain labor, the minimum wage being $4. There are several reasons that account for the present abundance of labor. There has been the usual migration into California from nearby sections where there is little winter work. The cessation of war activities has, of course, thrown many men out of work. The copper mines have either closed down completely or have curtailed production greatly. The same situation obtains in the lumbering sections. Owing to the high cost of construction, very little new work is starting. The public utilities are doing only maintenance work. Finally, but not least, the soldiers are returning.

In St. Paul the largest employer of labor, at the present time, is the Armour plant at South St. Paul, where 42½c. per hour of a ten-hour day is paid. Paving contractors, who expect to bid on a large amount of city work, seem to think that labor may drop to 37½c. about July, but that this rate will mark the minimum for 1919. Contractors in the Northwest do not anticipate a surplus of labor after the season opens. There is a difference of opinion as to the number of unemployed at the present time. Building contractors, who are not doing much work, say that there are 15,000 men in St. Paul and Minneapolis. Busy contractors deny this. As an indication that small municipalities will go ahead with their paving programs, one contractor points out that Tracy, Minn., has just let a contract for concrete pavements at $1.87 per square yard, against last year's contract price of $1.57 for work under the same specifications.

In St. Louis there is a surplus of common labor. On sewer work the rate has fallen to 35c. an hour. On brick work the wages paid are 27c. to 30c. On grading and concreting the minimum is 25c. to 27c. These are the rates paid by general contractors. Union labor in the building trades has just received an advance, but there is practically no building work going on at present.

In Birmingham, Ala., and vicinity there is a surplus of common labor, according to local employers, owing to the temporary closing of the large furnaces and the curtailment of production by some of the coal mines. Common labor is paid from $2.50 to $3 a day. The Board of Revenue of Jefferson County is paying $2.50, and is obtaining at this figure all the labor required for the work of the county. Contractors are paying, in a number of instances, $3, and in some cases slightly more. It is reported that there is a considerably greater surplus of skilled labor than of common; but the contrary is asserted by several contractors.

The City of Dallas pays labor $2.50 to $2.80. Contractors pay building laborers 30c. an hour; hod-carriers, 35c. and 40c.; sewer and paving men, $2.50, $2.80 and $3; for eight-hour days in all cases.

In Pittsburgh hod-carriers, mortar mixers and skilled laborers are paid, under the union scale, 60c. per hour, $4.80 per day, $26.40 per week of 44 hours. Common laborers receive 45c. per hour, $4.05 per nine-hour day, $25.00 per week of 54 hours. These rates hold until further notice, as there is no expiration agreement, and there are therefore no arbitration rules.

In Kansas City labor is plentiful. It is reported that many returned soldiers were employed as common laborers, but shortly were dismissed on request of the unions. Several soldiers applied for admission into the unions, but were informed that for the present no new members were being accepted. No non-union labor is employed in the building trades in this city. On street paving, on the other hand, only nonunion labor is used. The schedule paid on brick, concrete or stone-block paving is as follows:

Crafts	1919
UNSKILLED	
Rock wheelbarrow men	$0.40
Shovelers	.40
SKILLED	
Concrete graders	$0.55
Brick setters	.65
Stone setters	.75
Roller engineers	.75
IN ASPHALT PAVING—UNSKILLED	
Rock wheelbarrow men	.40
Shovelers	.40
Clean-up men and roustabouts	.40
SKILLED	
Smoothers	.45
Tampers	.45
Concrete graders	.55
Roller engineers	.75

SUMMARY

The foregoing can be best summarized by a table showing conditions—rates, hours in a working day, availability and classes of common labor—in the important centers of the country. Such a tabulation follows:

COMMON LABOR TODAY

(In 3rd column, P means labor is plentiful, S means scarce)

City	Rate per 8-Hour Day	Situation	
Birmingham	$2.50	S	
Boston	3.20	P	
Dallas	2.40	..	Buildings
Dallas	2.80-3.20		Hod carriers
Dallas	2.50-2.80		City
Dallas	2.50-3.00		Sewers (and paving)
Kansas City	4.20		Buildings
Kansas City	3.20		Nonunion
New Orleans	2.40	P	
New York	3.50-4	S	Pick and shovel
New York	4.00-4.50	S	Semi-skilled
Pittsburgh	4.05 (9 hour)		Common
Pittsburgh	4.80		Hod carriers
San Francisco	4.16	P	Shipyards Macy award
San Francisco	4.64	P	Shipyards government owned
San Francisco	3.50-4	P	Nonunion
St. Louis	3.50 (10 hour)	P	Sewer
St. Louis	2.50-2.70 (10 hour)	P	Concrete
St. Louis	2.70-3 (10 hour)...	P	Brick
St. Paul	4.50 (10 hour)....	P	

Construction Materials

The general price tendency is downward. About half of the construction materials have declined, the other 50% remaining firm. Of course, the principal movement was in iron and steel, as follows: Pig iron, basic, to $25.75 per ton, reduction $4.25; 4-in. billets, to $38.50, reduction $5; sheet bars, to $42, reduction $5; slabs, $42, reduction $5; skelp, merchant bars, sheared plates and structural base, No. 28 black sheets, No. 10 blue annealed, No. 28 galvanized sheets, all reduced $7 per net ton. As for rails, both standard bessemer and openhearth were lowered $10 per net ton, to $45 and $47, respectively. Steel and iron pipe were lowered 3½ points. These new prices are not arbitrary prices fixed by the Government, but are prices suggested by the Government and met by the manufacturers. The Government has committed itself to make purchases at these prices and has recommended the same course to general consumers. Every indication points toward a continuation of the new schedule. The decrease was not the result of panic. Its moderateness proves that it was arrived at coldly. Many buyers expected a more substantial reduction. That the Government accepts this revised schedule and agrees to do business under it indicates that the schedule is the minimum that can be made under present conditions.

All precedent is against a sharp decline this year. Except for steel products, sewer pipe, lumber in certain sections, and dynamite, the market is practically as it was a month ago. Prices will continue to fall, but not appreciably this season. Whoever has a project that should be got underway this year may call for bids and award it to the lowest bidder, feeling practically certain that he is not only getting it done at the best price obtainable this season, but that he is helping to turn the wheels of industry at large.

WHAT THE COUNTRY SAYS

Minneapolis has just let the following contract for paving materials for 1919: 100,000 bbl. of cement at $2.30 (without bags) f.o.b. city, to P. G. Speaks and to the Landers-Morrison-Christenson Co., local concerns; 500,000 sq.yd. of 3½-in. yellow-pine creosote blocks at $2.07 per square yard f.o.b. city, to the Central Creosoting Co.; 100,000 sq.yd. of brick pavers at $1.45 per square yard, to the Streator Clay Mfg. Co. The present price of cement, in carload lots, is $2.40 net in the Twin Cities. Wood blocks are quoted at $2.20 per square yard.

Probably the liveliest class of construction throughout the country is street and road work. It is, therefore, interesting to note the following sharp decline in the price of wood blocks, just reported in St. Louis, as shown in the table at the top of the next column.

This reduction is probably due to exceptionally keen competition. It is allaged that bidding in St. Louis by manufacturers not of that city reduced the price of wood block in a recent letting to less than the figures given in the table.

DECLINE IN PRICES OF WOOD BLOCKS, ST. LOUIS

Size	Per Square Yard Mar. 1	Apr. 1	Decrease
3½-in.	$2.45	$2.19	$0.26
4 in	2.60	2.50	.10
3½-in., Minneapolis specifications	2.40	1.94	.46
4 in., Minneapolis specifications	2.55	2.25	30

Stanolind asphalt in St. Louis has declined $3 per ton (in bulk), $3.40 per ton (in packages), owing, apparently, to heavy stocks. The same is true of Texaco, the price of which is slightly above that of Stanolind. Common (salmon) brick has dropped from $12 per 1000 to $10, while paving brick lowered from $28 to $26. Brick manufacturers assert that these decreases were made to stimulate construction, and that they will incur a loss unless a large volume of business ensues. The reduction in the price of sewer pipe is apparently on the same basis. It is stated on authority that the reduction most desired in St. Louis would be in cement.

In Kansas City there is practically no change since last month. The stated belief is that prices, except of lumber, may decrease in harmony with the drop in steel. The immense campaign now on, however, may create a demand for materials that will hold up the present prices for a time. Considerable public work is underway and much more scheduled. The largest job is the 23rd. St. viaduct, let to the A. S. Hecker Co., Cleveland, for $716,000, which includes a $50,000 profit fee. A $1,500,000 sewer contract and $900,000 worth of dikes for flood protection are to be let soon.

Everybody is anxious for building operations to get underway. From Chicago comes the encouraging report as to the building permits issued in the last three weeks of March shown in the accompanying table.

ANALYSIS OF BUILDING PERMITS, CHICAGO, IN LAST THREE WEEKS OF MARCH, THIS YEAR

Week Ending	No. of Permits	Residences	Stores	Factory	Storage	Miscellaneous Buildings	Tatal
Mar. 15	49	73	4	4	2	4	87
Mar. 22	58	80	1	3	5	4	93
Mar. 29	..	124	6	6	5	7	148

Week Ending	No. Over $100,000	No. Over $50,000	No. Over $5,000	No. Less Than $5,000	Total Amount
Mar. 15	None	2	19	28	$521,000
Mar 22	2	3	19	34	1,370,500
Mar 29	3	3	42	40	1,437,000

While on the subject of building permits it may be worth while to give a comparison of values issued in February, 1919, and the preceding year in five of the larger cities of the Canadian province of Quebec, as indicating that building work is increasing outside the United States as well as inside our country.

City	February, 1919	February, 1918
Montreal	$151,740	$77,045
Quebec	53,630	25,147
Sherbrooke	90,000	....
Three Rivers	24,800	17,000
Westmount	....	15,500
Total	$320,170	$134,692

Society Considers State Legislation

ENGINEERS' meetings to discuss public affairs are sufficiently rare to warrant calling attention to a recent meeting held by the Western Society of Engineers for the purpose of informing its members as to various measures now before the state legislature. The main purpose was to arouse engineers to a broader sense of their responsibilities and opportunities as citizens. Several phases of the general subject were illustrated by a review of bills affecting engineers and engineering work. There were talks by a state senator, the engineer of a public service commission, an architect and the secretary of a civic organization. It is worth noting that the attendance was larger than at many of the meetings when technical subjects are presented. There is a wide field for activity along such lines, and it is to be hoped that the society will take further steps in this direction—including both city and state legislation—and that other societies will follow its example.

Interest in Future of Civil Engineers' Society

IT WOULD be erroneous to interpret the failure of the members of the American Society of Civil Engineers to express themselves freely to the Development Committee, commented upon recently in these pages, as evidence of a lack of interest in the society's future. Wherever two members are gathered together, particularly in the Middle and Far West, there society activities come under discussion. The interest is intense; nor is it a birth of yesterday nor of last year. For a long time the demand for activity has been growing, and that demand has become tempered with impatience because of the inaction. Nevertheless, human nature is the same in the civil engineer as in other members of society. We all have opinions and express them freely to our friends, but we communicate them to the press or to official bodies only on request or when the situation is of a nature that makes it impossible to withhold comment. The views are existent. They are receiving constant expression man to man. The bringing of them to light is but a problem of proper stimulation or of providing the proper forum.

Efficiency and Low Cost In American Shipbuilding

BELATED references to shipbuilding costs are found in the report made by Edward N. Hurley on his European trip in behalf of the Shipping Board. Until this document appeared, two weeks ago, the Emergency Fleet Corporation and its parent, the Shipping Board, published no cost figures save for a few general statements before Congressional committees. However, what Chairman Hurley now says about the cost of shipbuilding is much less important in its specific data than in its strong assertion of his conviction that we can build as cheaply as foreign shipyards. Not only as cheaply, he intimates, but even more cheaply if we will further increase our efficiency. This is a conviction that needs to be emphasized more and more, and supported in thorough fashion by facts and reasons. It is necessary to get all cost-pessimism out of the shipyard. Some of our best yard managers are victims of the belief that shipyards abroad—anywhere—are predestined to build ships more cheaply than we can. Such a conviction paralyzes shipyard effort. Knowledge and study of costs can remove it.

Overtime Work Decreases Efficiency

OVERTIME is so seldom named in listing the influences which tend to reduce the efficiency of labor in construction that its indictment by J. B. Lippincott in *Engineering News-Record* of Mar. 27, 1919, p. 605, deserves comment. Many causes led to low labor efficiency in our recent war construction, but some very shrewd observers have asserted that none was more potent than the wholesale indulgence in overtime work. Besides the normal reduction in output of 25 to 50% expected of men in overtime hours, greed for large pay, due to knowledge that overtime was encouraged, decreased output in straight-time hours. It is the merit of Mr. Lippincott's article that in some measure it evaluates this effect instead of expressing it in general terms. Overtime work as a practice is one of the most vicious sins into which the construction manager can fall. If others who, like Mr. Lippincott, have close knowledge of war construction, would in a similarly exact manner recite the lesson of experience with overtime, they would help greatly in clearing up the confusion which now exists. In particular, they would help to free the cost-plus contract from the criticism made by many, who know it only as a war measure, that it encourages workmen to loaf and shirk.

New York City Starts Sewage-Treatment Program

WHAT may be regarded as a beginning of a sewage-treatment program for New York City was described on p. 674 of our last issue. We do not mean that fine screens are sure to be adopted at each of the numerous treatment works that the peculiar topography of New York City seems to require, but merely that a start has been made in accordance with the general principles deduced from the long and detailed studies of the Metropolitan Sewerage Commission. The earlier fine screens at the Brooklyn sewage experiment station should not be overlooked, but they seem to be in a different class

from those at Dyckman St., which, with the grit chamber, compose the first plant built to treat Manhattan sewage and perhaps may be regarded as the first permanent modern plant for the city. Inasmuch as fine screens have some decided advantages for New York conditions, and since data for this type, as applied to American sewage, are few and not readily comparable, it is to be hoped that thoroughgoing scientific observations on the Dyckman St. screens, yielding both physical and financial unit-volume data, will be made. If New York City would lead the way some at least of the other cities using fine screens might be expected to follow—to the advantage of both New York and the country at large.

Advancing Views on Railway Labor Relations

CHANGING labor conditions are keenly appreciated by railway engineers. Track labor, drawn from the very lowest strata of the unskilled-labor supply, has in the past been treated with a thoroughgoing neglect of its human aspects. But in the light of the new labor conditions that have arisen since we took up arms two years ago, it is coming to be understood that efficiency no less than human justice calls for a different attitude. More consideration must be given to the human element, said a speaker at the recent meeting of the American Railway Engineering Association. He demanded that railway men work ahead toward the future demands of a public sentiment, rapidly developing not only here but all over the world. And the succeeding speaker, emphatically confirming this view, stated, "There has been more progress made by the railroads of this country in handling and caring for their common labor during the past year, I think, than in ten years before." He asked for further careful attention to the matter during the coming year. The speakers were seasoned railway men. Their years of experience are warranty that no sudden enthusiasm or impulse of oratory prompted their words, and what they said was but a reflection of general conviction among the men who direct the maintenance of our railways. There is a great promise in these new views. Most hopeful of all is the recognition of the fact that the doctrine of decent treatment of labor rests on sound reasons of efficiency, and that the high-priced laborer may, if properly handled, justify the larger wage paid him by the larger return he yields.

Scenic Highway Location Questions

DISREGARD of attractive scenery is charged against highway engineers by so many persons who influence public opinion that these engineers will do well to consider the subject. In their desire to attain long tangents, uniform grades and simple, easy curves, the improvers of highways have, it is asserted, forced the traveler to ride in cuts between banks which shut off picturesque views that are famous, and have compelled him to turn away from old, winding roads which offered beautiful scenes worth going miles to enjoy. We all know that the conservator of natural scenery detests any innovation that cuts a tree or drains a swamp. Many of us have felt the lash of his criticism even when we planned our improvements to meet his wishes to the best of our ability. He will never be satisfied; no specialist in artistic matters ever is satisfied But that is no reason why we should not do our utmost to assist the traveler to all the enjoyment of nature's charms, while doing our engineering duty of making his way smooth. The road located on paper may have the best grades and curves and the best balancing of cuts and fills, but when the line is finally run out on the ground and it is found that changes in it will certainly add to the pleasure of the traveler, those changes should receive very thoughtful consideration before they are rejected. Any other course wastes a natural asset and deprives the traveler of the best kind of enjoyment, without accomplishing any good.

Utilitarian and Scenic Need Not Be in Conflict

OBVIOUSLY, the point of view expressed in the preceding note brings into opposition the respective advocates of the scenic and the utilitarian highway. Between the two, however, there need be no real quarrel. Where roads obviously serve only light traffic andrun through a scenic district, greater emphasis can be laid upon the scenic feature. On the other hand, roads carrying heavy traffic through a flat or relatively uninteresting country need give little or no consideration to the scenic features. Only where heavy-traffic roads traverse a scenic district need there be a consideration of the two ideas and a balancing of one against the other. Obviously, common sense will control in the weight to be given to each factor. A point that needs emphasis, however, is that oftentimes the utilitarian purpose can be as well served by an interesting as by a dull road.

Pipe-Casing Job Furnishes Lesson in Co-ordination

COÖRDINATION of operations is absolutely essential in certain kinds of construction if reasonably economical results are to be secured. Road building is one of these kinds. A more unusual and also a more extreme example is the concrete casing of pipe lines. The linear extension of construction operations is great, and the volume of construction at any point is small. To schedule the performance of working gangs and machines so that each will be in close coördination with all the others, either adjacent or remote, becomes under these conditions an exceedingly complex problem. Its solution must be accomplished, however, if the work is to proceed smoothly and cheaply, and every example of successful solution, like that outlined on page 725, is helpful in perfecting procedure.

The necessary requirements for coördination on construction work of the kind being considered are: Extreme mobility of equipment, precise scheduling of performance, regular arrival of materials and supplies and prompt repairs of plant. Note how on the Louisiana pipe-line work fulfillment of these requirements was guaranteed. All equipment except mixers could be picked up by hand and carried ahead as fast as the men could walk. Corresponding mobility of mixing plant, which was too heavy for such quick movement, was secured by having two mixers, one of which was traveling ahead while the other was working. Materials supply was separated from the construction operations proper. Also, the detail task of handling and stocking materials on the work was separated from the general task of maintaining and routing deliveries. This subdivision of foremanship was extended to the pipe handling and also to the concreting operations. One concret-

ing foreman had the specific duty of keeping equipment in repair.

Construction seldom furnishes the opportunities which the factory offers for nice subdivision of the duties of foremen or for the application of functional foremanship, but the advantages of both need to be kept in mind by the contractor. The fewer the duties any one foreman has to perform the more precisely, ordinarily, will he perform them. Also, it is more easy to find the man who can perform one task well.

Comprehensive License Laws for Engineers

ENGINEERING license laws are being proposed and passed so rapidly that there is quite evidently no further need for argument to demonstrate the trend of the movement. It is rather only a question of what form the bills will take. The latest bills, abstracted on p. 616 of the issue of March 27 as well as previous bills which were compared in our issue of Feb. 27, 1919, p. 423, indicate the strong tendency toward the adoption of comprehensive laws including all classes of engineering—civil, mechanical, electrical, mining—also, in some cases, land surveyors as a separate and specific class. In the case of the proposed bills in Indiana (which failed to pass the last legislature), Michigan and Ohio, architects are also to be registered with engineers under a single law. The proposed Ohio bill goes so far as to include responsible assistants, even when working under a registered professional engineer or architect, on the plea that the law would be a farce if only the chief engineer of a city or large corporation, for example, need be registered while his many assistants in charge of work are not.

One of the essential features in any sound progress in this movement toward licensing is seen in the provision for specialized examinations. All bills authorize the practice of general engineering, even though separate certificates are granted. This is good practice. The examinations, however, should be devised to test the candidate in two particulars: First, as to his knowledge of fundamental principles underlying all branches of the profession, and second, as to his specific knowledge in the higher technique of his own specialty. Examinations of this type should properly safeguard both the profession and the public, and make the granting of general engineering licenses feasible and logical.

Whether a single comprehensive law to include architects as well as engineers is the best form, depends directly upon whether the architects really desire a law which will not overlap or interfere with any law proposed by the engineers. Aside from the tendency to draw the two professions into closer relation, which would naturally result in their working together for the passage of a common law, there seems to be no valid or convincing reason for bringing both professions under the same machinery of registration.

Whether those states in which surveyors or civil engineers only are now licensed will soon join the movement for more complete protection, as has just been done in Idaho, remains to be seen. In any case, the tendency toward comprehensive licensing bills is certainly strong and should be advanced by all engineers who have faith in the advantages of public recognition and believe in the necessity for greater solidarity in the profession.

Lessons from Professional Organization in England

PROBABLY no discussion of professional organization has had as wide a reading in this country as that which will be accorded to the abstract in this issue of the report by Sidney and Beatrice Webb on professional organization in England. The conditions disclosed bear a striking similarity to those that obtain in this country. On second thought one realizes that such would be the case, for the reasons for class groupings are always fundamental; the variations, therefore, are accidental rather than essential.

It will help to emphasize the applicability of the Webb findings to conditions in this country if we visualize the drama of American engineering society activities. Only a few years ago the four national societies alone occupied the stage, pursuing an even, dignified technical course. The next actors to appear were the local engineering societies, content for a while to play a relatively important rôle, but having a tremendous reserve of suppressed virility. Closely following were the sections of the national societies, bolder than the parents, becoming more indignant and more articulate as the insensibility of the parents to their needs and desires became apparent. Then entered the American Association of Engineers, young, unhampered by precedent, fearing not to tread where the older societies hesitated. Then came the Engineering Council, erected partly out of a desire to do the broader things demanded by the profession, partly as a means of defense against the swift-moving organizations that threatened to steal a march on the older societies. Last to enter are the unions, enunciating the theory that only by collective bargaining, by combining on demands, can adequate compensation be secured.

Nor are the characters in this drama of engineering organization willing to stand about and pose. Some of them—the older societies—were content formerly with that part. Now the action is swift. The initiative proceeds from the younger members of the cast—the locals, the sections and the A. A. E. The older societies are plainly on the defensive. Moreover, their weapon of defense, the Engineering Council, is itself in difficulties. The progressive elements damn it as too conservative and unrepresentative; the conservatives contend that it is too progressive; they question its budget, one of them has refused to appropriate the amount the council requested for the National Service Committee. The locals, meanwhile, in a corner by themselves, earnestly debate national problems and seek a mechanism for united action, while here and there are voices shouting for the submergence of all elements of differentiation and the formation of a single society for the whole profession.

But the action does not end there. Someone raises the question of licensing, and immediately there is a new hubbub, though shortly those demanding licensing prevail. However, in the wrangle the justifying argument has been changed from "protection of the public" to "the advantages to be derived from having a legal status."

The plot now becomes deeply involved. The clear cleavage between groups disappears, as factions split off due now to one issue, now to another, until it is apparent that there is need for someone to come in, to demand a truce, that consideration may be given calmly

to conflicting aims, that through crystal-clear statement harmony may be obtained when harmony is possible. Where the conflict is fundamental, clear statement will enable the dissenting groups to direct their courses more intelligently.

Feeling this need, let the reader turn to the Webb report. He will find there a keen analysis touching on most of the elements of the plot of the drama of American engineering society organization. He will find there the story of a matured conflict between the leaders and the rank and file; he will find union tactics discussed, not as a novelty, but as an abiding feature in even the most eminent of professional organizations; he will find argument justifying a multitude of engineering societies; he will find raised the question of amalgamation versus federation; he will find licensing (or registration, as they call it in England) treated as an essential feature of professional-society activity; he will find, above all, an insistent emphasis upon the need for placing ideals of community service side by side with the present selfish aims of professional societies.

One comes away from the report with the feeling that we are but beginning in the organization of engineers. and that we can modify our society activities very materially without detracting from the standing that we desire them to have. It is a bit of a shock to learn that eminent professional bodies have resorted to union methods. Yet we cannot dodge the advantages to some of such procedure, even as the Webbs do not condemn it.

This much, certainly, the report should do for us—make us more tolerant in the working out of our problems. There is no doubt that the older societies look with deepest apprehension at the growth of the A. A. E. and of the draftsmens' and inspectors' unions. To them, the structure of professional organization seems to be attacked at its very foundation. Yet does not the Webb analysis help us to conclude that the movements are but expressions of the needs of the rank and file, as against those of the leaders of the profession? The A. A. E. is already talking in those very terms, contending that it represents the "employed" engineers, and that the older societies represent the "employing" engineers.

Should we not, too, soften our intolerance of the licensing movement as a result of the Webb analysis· should we not get a clearer view of the ideal of general service, and of the tremendous difficulty of so organizing the profession that all its groups will be articulated?

Certainly we should be directed by the report back to fundamentals. There must be recognition that no power on earth can thwart movements that serve the interests of a large group, however much those interests may depart from our traditional views. Wherever there is a group of goodly size with interests clearly different from those of other groups, there will be found a new movement, a new society. To attempt to destroy it is futile. The part of wisdom is to help it find its place in the whole scheme, fit it in if it can be fitted, letting it work out its specialized problems itself, but in coördination with the interests of the whole profession.

Then should come recognition of the fundamental of conservation of energy—the elimination of duplication. Then the fundamental of efficiency—the recognition that real service lies not in declared intention, but in works, and in works based upon heartfelt sympathy, not on the cold logic of theoretical advantage. For example, as between the Engineering Council and the A. A. E., that one will dominate eventually which comes nearer the heart of the greater number in the profession.

If the fundamentals of professional organization are to be summed up in a sentence, we would say that self-interest, the development of technique, and service to the community are the three principles on which it is to be based, the service-to-the-community ideal enlightening the self-interest no less than the ideals of scientific research and development, which have been the important leaven heretofore. If these principles are kept to the front in all discussions of society organization, the difficulties will dissolve themselves more easily and the fitting of the parts into the whole will become a less complex task. Tolerance, too, will help, and to this the Webb report should make no small contribution.

Engineering Standardization—A Problem

A REVOLUTIONARY change in the mechanism of our technical and industrial life was inaugurated during the war period, by the formation of an Engineering Standards Committee, a joint committee of five national engineering societies. The new movement diverges sharply from the established system, under which competent bodies of specialists formulate standards of shape and quality for commercial products involved in technical needs.

The Engineering Standards Committee represents centralized effort in place of logically distributed effort. As a mere piece of centralization it has no special claim to support, for we already have possibly too much unconsidered centralization. But the new organization will stand or fall according to its effect in producing good or bad results. If it will disrupt and rearrange large portions of the present system, built up by several decades of labor and now in full and successful operation, it must show that it will accomplish a net benefit. Up to the present it does not appear to have received much attention, certainly not the wide and careful consideration that it merits. The individual engineer, in fact, has had no opportunity to study it.

Taken up as a war-time measure, when minds were not inclined to weigh the minutiæ of any undertaking that seemed to promise war service, the formation of the Engineering Standards Committee is now to be thought of solely with regard to peace purposes. The new body has produced no results so far. A more active period lies ahead, however. The problems which this coming activity involves are of large scope.

No great movement can succeed, whether in engineering or elsewhere, unless based on a commanding need, and unless planned with care to meet that need. What need will the Engineering Standards Committee meet?

Under present practice standardization is dealt with by bodies obviously competent in the specific subjects dealt with. Natural processes are relied upon to direct the work in proper channels. There is automatic selection of the appropriate tribunals to formulate the various standards, and equally automatic acceptance of well drawn standards. In many years of standardization this process has worked with entire success.

So, for example, the Master Mechanics' and Master Car Builders' Associations deal with uniformity and adequacy in the proportioning of cars and locomotives. Screw threads and fittings and many other subjects have been taken care of by the American Society of Mechanical Engineers. Quality requirements and uni-

form test and acceptance methods for a large range of material are studied to remarkably good effect by the American Society for Testing Materials, and cement-testing methods by the American Society of Civil Engineers. The latter society in the early days, and more recently the American Railway Association, promoted uniformity in rail sections. Bridge design, tie practice, and a host of track details are in the care of the American Railway Engineering Association. Lumber, cast-iron pipe, and other items in very large number are handled by other societies, all competent and recognized as such. So much for organized standardization. But far more important and more constant has been the standardization going on through industrial and commercial processes—as an example, standardization of electric lamp sockets. And one distinct virtue of the system now prevailing is that it avoids all interference with this natural growth of standards.

This complex mechanism has operated in prompt and delicate response to the developing requirements of industry. It has rarely sought to go ahead of these requirements, and has never succeeded in so doing.

What gain will be realized by the new system? This question is primary. No showing of advantage has yet been made, so far as we are aware. There has indeed been talk of conflict between existing organizations, and of failure to coöperate, requiring the firm hand of recognized leadership to bring about harmony. But what are the specific instances? The few cases of recent years in which there has been conflict of authority, or lack of joint consideration, do not, we believe, show a need for controlled coöperation, but contained in each case evidence that the field of work was not yet ripe for effective standardization. But there are further questions to be faced, questions that have not yet been answered; we desire to suggest a few of them.

What are engineering standards? What, in other words, is the field of the new committee? Can it define and delimit its scope, or does it propose to act on the plan of taking over everything resembling standardization work that may come into view? Frankly, we doubt whether the engineers and industrial men of the country are prepared to give a blanket warrant to a new and powerful body to bring about uniformity in any and every subject. Premature standardization is bound to prove confusing, and temporarily fettering to both engineering and industry. And, on the other hand, the delay to proper standardization from adding another element of mechanism may prove equally annoying.

The dangers of a lack of delimitation of scope are obvious, and yet compel scrupulously careful consideration. But it needs to be remembered also that questions of engineering design are often closely interlaced with those of standards, and that, if an unlimited field of action is at hand, mistakes are by no means unlikely, especially at the hands of a body acting by virtue of judicial character rather than competency.

Are we backward in standardizing? With our present mechanism we have taken account of all needs of technical industry as they developed; and standardization may easily run riot if a ponderous machine once gains momentum. Has there been failure to accept standards that have been formulated? Automatic acceptance has been readily accorded on merit to satisfactory standards. Shall we gain through standardization by fiat, by rubber-stamp approval, as a substitute for voluntary acceptance? These are but a few of the many questions surrounding the new movement, questions that address themselves to every member of the profession.

When so many doubts surround the matter, it is surprising indeed that the movement went ahead so smoothly and silently. To look back a few months: It was initiated in the early summer of 1917, with a view to building up an analogue of the British Engineering Standards undertaking, now a dozen or more years old. Whether any regard was had for the fact that conditions here are radically different is not apparent. At the time the first Engineering Standards commission was formed in England there was a deplorable lack of uniformity as well as of means to bring about uniformity. Every mill, for example, rolled different shapes and sizes of I-beams; and this subject was in fact one of the first to be taken up by the commission. Here, on the other hand, an extensive commercial automatic standardization had progressed far, and elaborate society work had long been under way, as already mentioned. These fundamental differences, if noticed, did not discourage the organizers of the American movement, however. After more than a year's work the present committee emerged. It has three representatives from each of the national societies of civil, mechanical, electrical, mining and testing engineers. It is to take control of all existing standardizing bodies, and act not through its competence but by exercising supreme-court judgment on the competency of others.

If representative character is needed to give the authority which this Engineering Standards Committee is to exercise, it has not been realized. Present difficulties surrounding the committee involve this very question, and a reorganization may be brought about. But will even a broadly representative committee or board add authority to a well drafted technical specification by its approval? Will a specification for steel rails, to take a definite example, gain in authority by approval on the part of a body composed of electrical, fire-insurance and boiler experts? This, after all, is one of the inevitable foundation questions, a psychological one rather than one of engineering method.

What we have said is of direct moment, we believe, to engineers in every branch and every society. Two groups of existing organizations, however, are additionally concerned in an even more personal way, as the fields in which they have long worked, with well earned recognition, are now to be gathered into the sphere of the Engineering Standards Committee. The one comprises the technical railway associations, chief among them the American Railway Engineering Association. The other consists of the American Society for Testing Materials. It seems likely that the railway associations will continue their work without thought of the new body, and will maintain their full authority over the matters entrusted to them. With respect to the American Society for Testing Materials, however, the case is otherwise. All its interests, and the peculiarly enthusiastic collaboration of many minds which for years has distinguished its activities, are involved in the risk of a seriously weakening process. No member of the testing society can be indifferent to the developments in connection with the Engineering Standards Committee; nor will any engineer who, though not affiliated with the society, has observed its excellent work, wish to see the new movement proceed if it is to take from the interest concentrated in its committee work, or reduce the service it renders.

Wood Construction Feature of Charleston Port Terminal

Design at Army Supply Base Largely Dictated by War Emergency, But Docks and Warehouses Illustrate Modern Use of Timber for Such Work

By Hunley Abbott
Engineer of Docks, Charleston Port Terminal, Charleston, S. C.

TIMBER construction mainly was used for the docks and warehouses of the Charleston port terminal, an Army supply base on the Cooper River at Charleston, S. C., because timber was the material most readily available for the rapid construction demanded last summer when the work was started. Concrete plans were originally prepared for the docks, but the pressing demand for speed necessitated the change to wood, although some concrete dock work was done after the armistice was signed. The timber details, however, represent the modern use of an old material in harbor structures, and as such are worth describing.

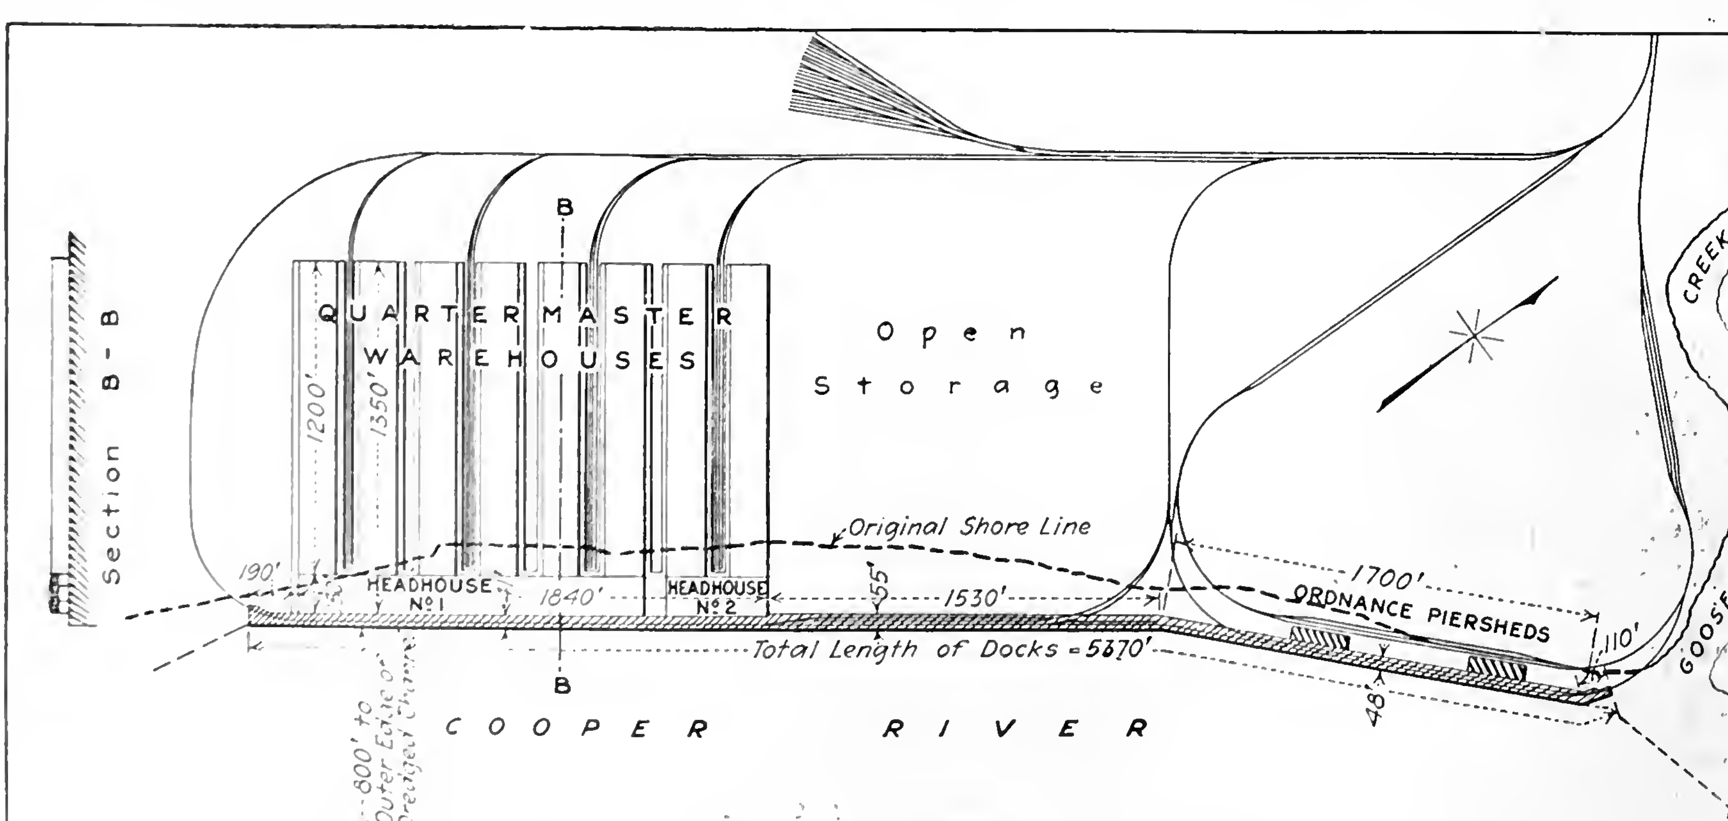
The Charleston port terminal is really three adjoining terminals: (1) A remount station and animal embarkation depot for the empoundment of Army horses and mules and their shipment abroad; (2) an ordnance depot for the storage and shipment overseas of ammunition, powder and TNT, and (3) a quartermaster depot for the storage and shipment of all quartermaster materials. It is only the quartermaster depot which will be described in this article.

The quartermaster depot consists principally of six large warehouses and two large sheds lying parallel to each other and at right angles to the waterfront. Connecting the outshore ends of these buildings are two headhouses, one running along the ends of the six warehouses and the other along the ends of the two sheds. On the outshore side of the headhouses, and connecting therewith, is the dock. The combined floor area of these warehouses and headhouses is 1,700,000 sq.ft. To the north of the warehouses is an open storage area, formed by dredge-filling the marsh, gridironed with tracks and with an available storage space of 1,320,000 sq.ft. Also, there are tanks and water towers, a power house, a locomotive roundhouse, several fire houses, barracks for about 3000 guard, stevedore and other operating troops, an ice plant, a bakery, a hospital and many other miscellaneous structures.

The warehouses and sheds are each 160 ft. wide by 1200 ft. long, with an 80-ft. space between buildings. A 20-ft. platform runs on either side of each warehouse. Three lines of track run down between each pair of warehouses and sheds. These connect with the yard trackage and are used for unloading incoming material. The elevation of these tracks is such as to bring the floor of the car flush with the platforms and warehouse floors, which are at El. 13, zero being mean low tide in the river.

The details of construction of the warehouses follow standard Construction Division practice: Wooden floors, columns spaced 20 ft. on centers and purlins, with tar and gravel roof. The floors are designed for a live load of 500 lb. per square foot. The warehouses, being built on marsh land, rest on pine piles, spaced on 6 ft. 8 in. centers both directions, and which extend above ground and are cut off and capped with 10 x 12-in. floor stringers. The main walls are of tile and brick, and the warehouses are divided transversely every 100 ft. by brick and tile fire walls entirely free of openings, thus dividing the warehouses into a number of fire-insulated compartments. All warehouses are one-story high, except that a second story is built on the lower end of warehouse No. 6 for offices, etc. All openings are provided with fire-resisting doors, and a complete automatic sprinkler system has been installed throughout these buildings, thus providing another safeguard against fire.

The headhouses are 150 ft. wide and have a combined length of 1840 ft. They are of similar construction to the warehouses except that they are considerably



PLAN OF THE TERMINAL END OF THE CHARLESTON ARMY SUPPLY BASE

higher and have a column spacing of 20 x 50 ft. with wooden trusses in the 50-ft. spans. There is a clear height of 20 to 25 ft. from the floor to the under side of trusses. The headhouses are divided into compartments by tile and brick cross walls every 120 ft., and are provided with fire doors and sprinklers, as in the warehouses. All the walls are supported on concrete foundation walls (supported by wooden piles) and the outshore headhouse foundation wall also supports the inshore end of the dock caps.

The columns resting on this outshore wall are of steel instead of wood, and project some 35 ft. above the roof, leaning forward at a slight angle to form a system of cargo masts extending the full length of the quartermaster headhouses. Between the tops of the masts are hung 15-in. I-beams, pin-connected so as to permit the I-beams to swing. Fastened to the web of the I-beam and depending below the lower flange are pin-connected shackles spaced 5 ft. on centers.

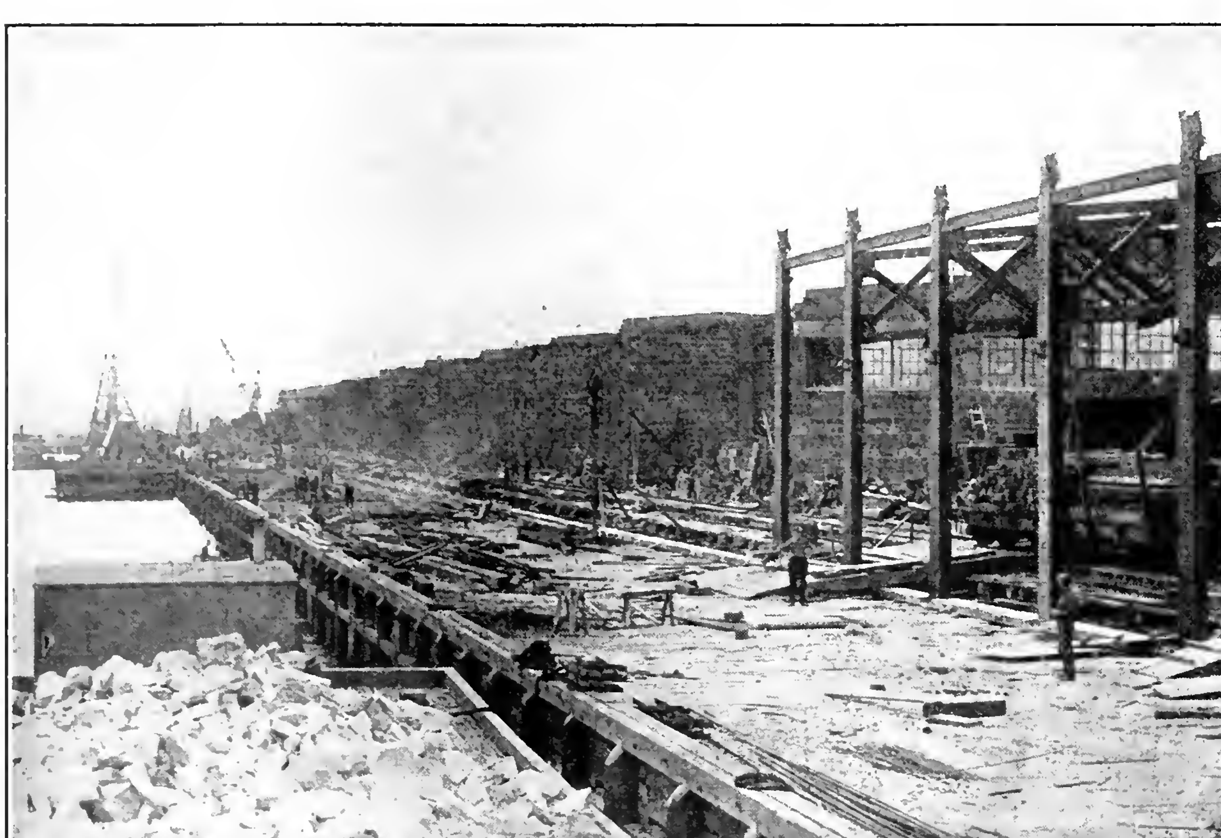
Extending along the front of the quartermaster headhouses, north through an open stretch of about 2000 ft., and in front of the two ordnance pier sheds, run the docks, which are slightly over a mile in total length.

The ordnance pier sheds and the quartermaster headhouses are built out in the water and are supported by untreated pine piles. The teredo is very active in the Cooper River even as far upstream as this terminal, consequently it became necessary to protect these piles from attack. This was done by driving wooden sheet piling in front of and returning shoreward to the north and south of the warehouses. Back of this sheeting, under the warehouse floors and surrounding the bearing piles, was pumped a dredged fill to El. 7.5. At this point there is an average tide of 5 ft. in the Cooper River, so this fill protects the piles at all stages of water. The sheet piling is of untreated lumber, and to protect it from the teredo it was originally planned to bank up filled material in front of it and under the dock, allowing it to slope out to deep water at the face of the dock. Owing to the very flat slope assumed by this material, however, and on account of the narrow width of the dock, it was not found possible to pile this fill up to the top of the sheeting without having the toe of it extend far out beyond the face of the dock. Therefore, a triangle of riprap stone was used instead. The depth of water at the sheet piling varied from 8 to 22 ft. Six-inch sheeting was used in the shallower depths, and 12-in. sheeting in the deeper water. The 12-in. sheeting ran 40 ft. in length and was made of 12 x 12-in. Oregon fir with 3 x 4-in. tongue-and-groove strips spiked thereto.

The progress of the work necessitated the placing of the fill behind the sheeting considerably in advance of the receipt of the riprap, and it was, therefore, necessary to brace the sheeting sufficiently to withstand this earth pressure. This was done by tie rods of 1¼-in. diameter, spaced 5 to 6½ ft. apart, passing through 12 x 12-in. wales at the top of the sheeting and tied back into a 12 x 12-in. deadman about 35 ft. in the rear. This deadman rested behind a row of warehouse piles, and two batter piles were driven, one on either side of each vertical pile in this row. The heads of the batter piles were cut with a vertical and horizontal face, the pressure being transferred to the batter piles by the deadman, and the upward reaction of the batter piles being taken care of by 12 x 12-in. chocks bolted to the vertical piles.

Additional resistance was provided by 3 x 10-in. cross-bracing on each row of foundation piles running at right angles to the deadman and extending from the deadman forward toward the sheeting. A cross-section through the 12-in. sheet-pile bulkhead is shown in a drawing. The bracing for the 6-in. sheeting is similar to the 12-in., but only one batter pile is driven at each vertical pile, and the cross-bracing is omitted. There is approximately a half mile of this sheet-pile bulkhead wall in front of the quartermaster and ordnance warehouses.

The original plan of the docks called for an all-concrete construction comprising concrete piles and a reinforced-concrete dock. When the job was very young and only a few of the piles had been cast, it became very evident that the inexperienced labor available here and the inherent nature of this type of construction would prevent the completion of this work in anywhere near schedule time. Since speed was "of the essence," this type of construction was thereupon abandoned, and a creosoted-pile and wooden-deck design was quickly prepared; this is the dock which has been built.



LOOKING ALONG THE DOCK FRONT OF THE CHARLESTON PORT TERMINAL DURING CONSTRUCTION

The dock widths vary from 41 ft. in front of the quartermaster warehouses, 55 ft. in the open dock north to a slight angle in the dock, and 48 ft. from there on north in front of the ordnance pier sheds to the north end of the dock, which terminates at the mouth of Goose Creek. The depth of the water along the dock front varied from 10 to 30 ft. This has been dredged to give 30

DOCK WAS BUILT OUT IN RIVER AND FILLED IN BEHIND LATER

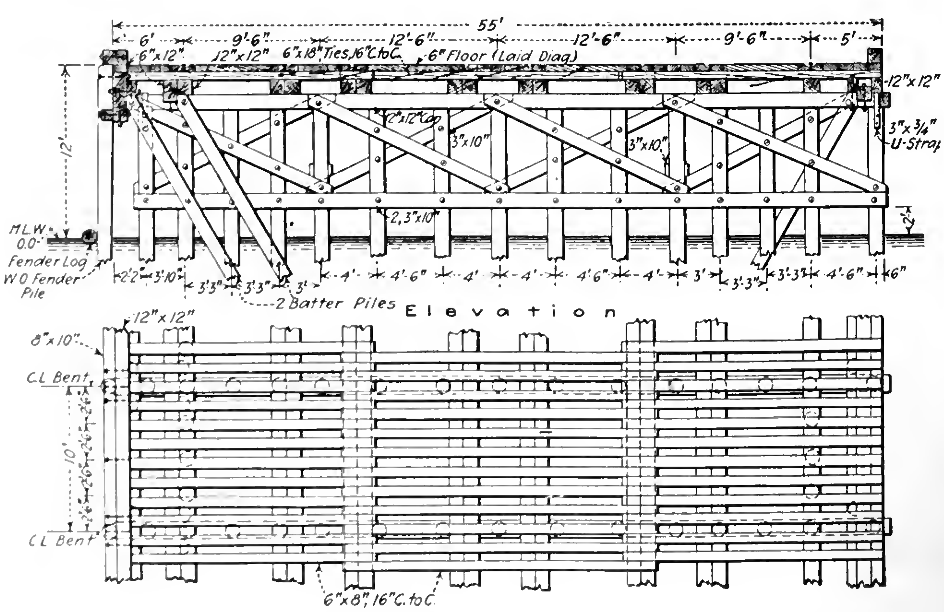
ft. of water below mean low tide throughout the entire length of the docks. A 400-ft. channel was cut from the navy yard up to this terminal, which channel widened out to 800 ft. in front of the quartermaster warehouses and to 1000 ft. in front of the ordnance pier sheds, thus forming a turning basin for ships. The dredged material, consisting mostly of a bluish-green clay, was used to fill in under the warehouses and on other marsh ground along the waterfront. Approximately 2,000,000 cu.yd. of material was moved to cut this channel, several rotating cutter dredges being used.

The docks are designed to carry a live load of 500 lb. per square foot, together with certain railroad and gantry loads. The floor of the dock is at El. 12, with a slight upward slope from face to rear. This floor comes flush with the warehouse floors where the two meet. All piles, except fender piles, are creosoted, the lengths varying from 40 to 80 ft. They are driven in bents spaced on 10-ft. centers, and each bent is capped with a continuous stick of 12 x 12-in. Oregon fir, drift-spiked to the piles.

A system of bracing on each bent extends from the cap down to El. 2. Two horizontal 3 x 10-in. timbers are bolted on either side of the piles at that elevation, and 3 x 10-in. cross-bracing runs between these and the pile cap, being bolted to the piles and the cap at intersections. All the bolts are of 1-in. diameter. It was originally planned to use creosoted timber for all this bracing, since it will be under water at high tide. On account of the delay in obtaining this creosoted material, however, untreated pine lumber was used. This will be eaten away in time by the teredo and will have to be replaced, and at the time of replacement creosoted lumber will probably be used.

On those sections of the dock that are in front of warehouses there are two batter piles in front and one in the rear at each bent. In the open sections of the dock there are four batter piles per bent in front and one in rear. The heads of the batter piles are cut so as to have a part horizontal and part vertical face. These faces bear against longitudinal timbers running over the pile caps and bolted thereto. At such point on the cap a 3 x ¾-in. steel U-strap ties the cap to a vertical pile, thus transmitting the upward reaction of the batter pile through the timbers and cap and down into the vertical pile.

On the dock in front of the quartermaster warehouses there is one line of standard railroad track and two rails spaced 19 ft. apart for a 5-ton gantry crane. On the 55-ft. wide section of the open dock there are three lines of railroad track and rails spaced 44 ft. apart



DETAILS OF TIMBER DOCK BETWEEN QUARTERMASTER AND ORDNANCE SECTIONS

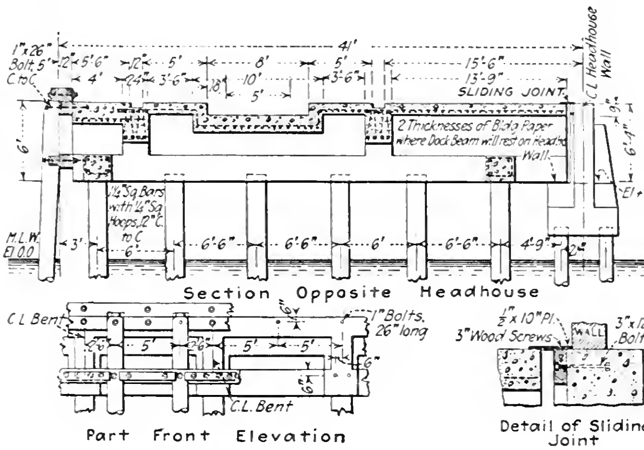
for a 10-ton gantry. Standard 80-lb. rails are used for the gantry tracks, and Russian rails 5 in. high with tie plates for the railroad tracks. Two 12 x 12-in. pine stringers are placed under each rail of the railroad track, and one 12 x 12-in. stringer under each gantry rail. Supporting this gantry stringer are three additional creosoted piles spaced between each bent, thus giving a pile every 2½ ft. under this stringer.

On top of these track stringers are laid 6 x 8-in. cross-ties spaced 16 in. on centers, and these ties also support the 6-in. floor in the neighborhood of the tracks. In places where no tracks occur the flooring is carried by 6 x 12-in. stringers 3 ft. on centers resting on a 6 x 8-in. timber spiked to the top of the cap.

Several heavy timbers are framed in on the face of the dock for stiffness, and a 12 x 12-in. bumping timber projects above the floor at the face of the dock and, in the open sections, in the rear also. White-oak fender piles are spaced on 10-ft. centers in front with an 8 x 12-in. fender cap and a line of 8 x 10-in. fender chocks.

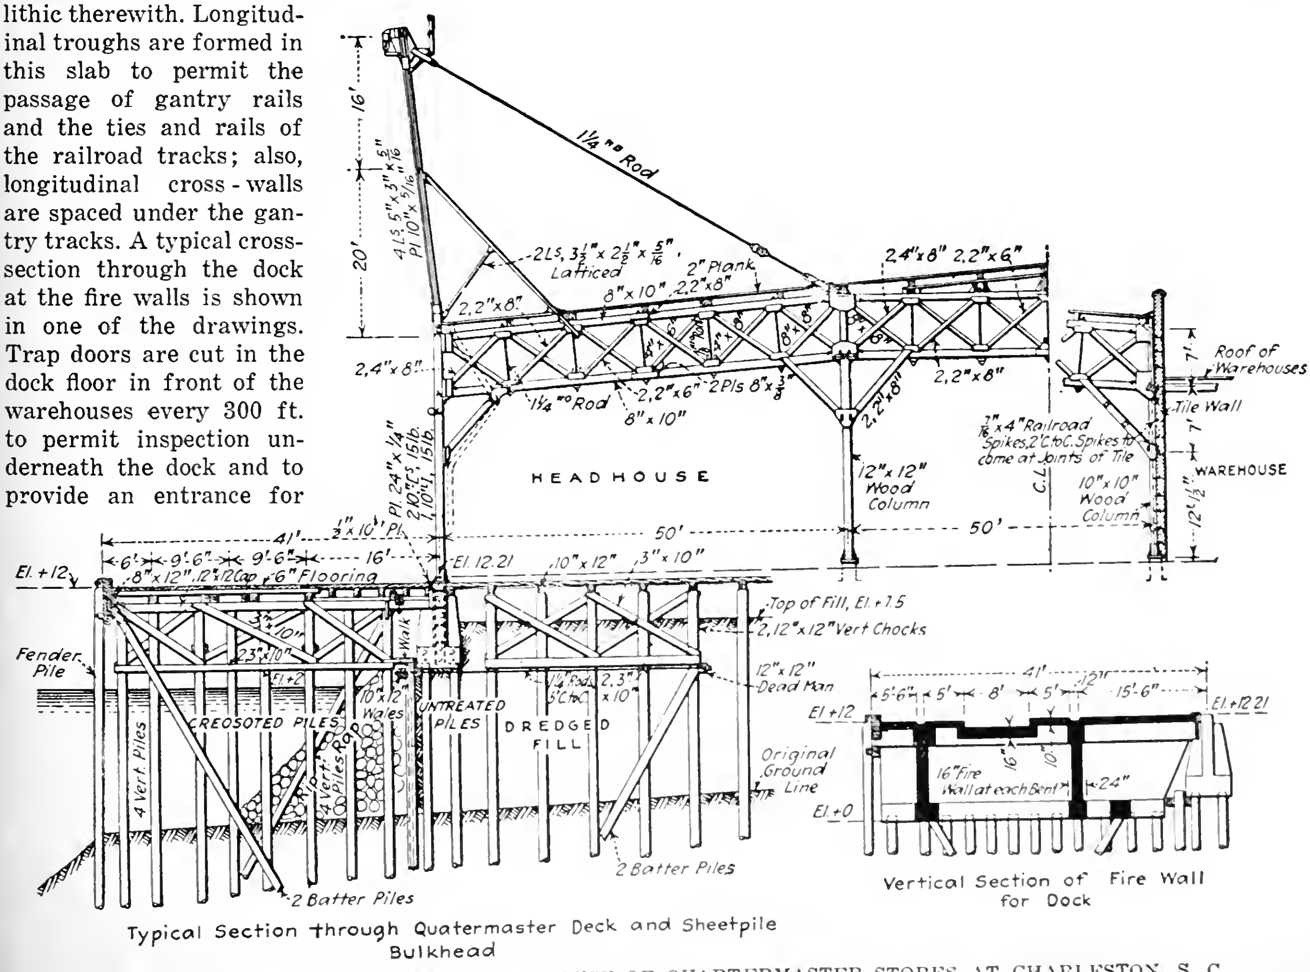
A 3-in. space is left between the rear of the dock and the front wall of the warehouses to allow for any possible movement of the dock when a ship is brought alongside. This slot is covered by a 10 x ½-in. steel plate.

The docks are divided into 300-ft. sections by double fire walls. The piles in two adjoining bents are cut off near low water, and a 16-in. concrete wall is built on each bent. The bottoms of the walls are at mean low water, and are tied together by longitudinal reinforced-concrete struts. A reinforced-concrete deck spans between the tops of the two walls and is monolithic therewith. Longitudinal troughs are formed in this slab to permit the passage of gantry rails and the ties and rails of the railroad tracks; also, longitudinal cross-walls are spaced under the gantry tracks. A typical cross-section through the dock at the fire walls is shown in one of the drawings. Trap doors are cut in the dock floor in front of the warehouses every 300 ft. to permit inspection underneath the dock and to provide an entrance for hose lines in case of fire. Standard types of mooring posts and cleats are spaced every 80 ft. along the outer edge of the dock. A group of dolphin piles was driven at the outshore corner at each end of each dock.



CONCRETE ALTERNATIVE DESIGN OF CHARLESTON DOCK WALL NOW BEING PLACED

When the armistice was signed and speed of construction became less vital, it was decided to use the concrete piles already cast to build 150 ft. of reinforced-concrete dock, in accordance with the first plan. These piles were 52 ft. long and 18 in. square, with beveled corners. The lower 2 ft. of length was tapered to a 6-in. square point. They were reinforced with four 1¼-in. square rods spaced 3 in. from the face of the pile to the center of the rod. The main rods were



DETAILS OF TIMBER DOCK AND HEADHOUSE OF QUARTERMASTER STORES AT CHARLESTON, S. C.

tied together every 12 in. by hoops made of ¼-in. steel. These hoops were spaced 4 in. for about 5 ft. at the head, and 3 ft. at the point of the pile. About 4 ft. from the head of the pile a short length of pipe 3 in. in diameter, was cast in the pile at right angles to the axis. This gave a convenient point to which to tie in handling the pile in the driver leads. The piles were cast on large platforms. Wooden forms were used for the piles, with a space of 9 in. between each set of forms, to facilitate stripping. When the concrete was sufficiently set these forms mere removed and were used again to form a pile on top of the previous one. In this way three tiers of piles were cast.

The piles are cut off at El. 6.5 with the pile reinforcing rods projecting 2 ft. about the cutoff, and a heavy concrete girder wall caps each bent of piles. This wall extends up to and is monolithic with a 9-in. reinforced-concrete floor-slab spanning between bents. Heavy girders are cast under the gantry rail, and a trough is left for the railroad track similar to that in the fire-wall construction. Two longitudinal struts brace the bottom of the bent caps, one strut near the front and one near the rear of the dock. A typical cross-section of this concrete dock is shown in one of the drawings.

After the armistice was signed, one of the ordnance pier sheds and the dock in front of it were abandoned; also a portion of the open dock between the quartermaster and the ordnance warehouses was omitted. All of the quartermaster warehouses and headhouses are built, however, together with about a half mile of dock in front of them; also 700 ft. of dock in front of the ordnance pier shed.

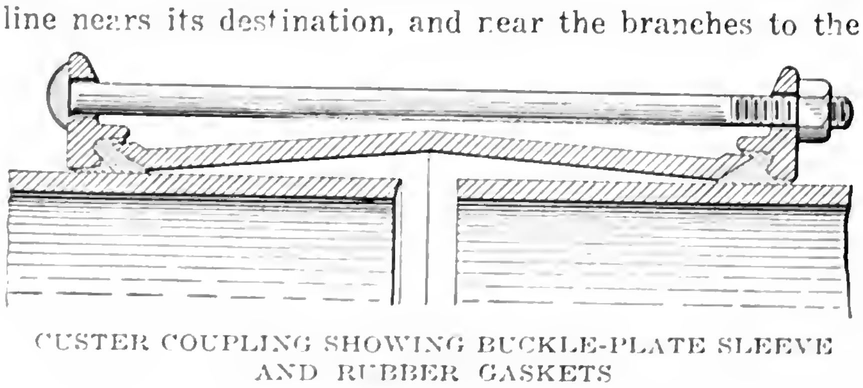
The total cost of this project will be approximately $17,000,000. The work was in charge of the engineering branch of the Construction Division of the Army, under the supervision of Col. Lincoln Bush, Lieut. Col. R. M. White, chief of the Port Terminal Section, and Lieut. Col. L. L. Calvert, supervising constructing quartermaster. Col. F. E. Lamphere was constructing quartermaster in charge of the work in the field. The Mason & Hanger Contracting Co. was the general contractor, and the Degnon Contracting Co. was the subcontractor on the ordnance magazines and part of the docks. The Atlantic, Gulf & Pacific Co. was the contractor for the dredging.

Constructs Largest Gas Line in the United States

Coke Plant Builds Gas Main 40 Inches in Diameter Laid Near Pittsburgh—Method of Construction and Joints Described

CONSTRUCTION of what is reported to be the largest gas line in the United States, and probably in the world, is now being completed for the Carnegie Natural Gas Co. The line has a maximum diameter of 40 in., is 11 miles long, has a daily capacity of 70,000,000 cu.ft., and is capable of sustaining a pressure of 200 lb. per square inch, but will actually work under a pressure of from 30 to 50 lb. It is being built to convey gas from the byproduct coke plant of the Clairton Coke Works to the Duquesne, Homestead, and Edgar Thomson steel mills near Pittsburgh. The joint used is of the Custer type, with rubber gaskets. The flexibility of this joint, due to its buckle-plate sleeve, is said to have made it much easier to obtain tight joints over this rough country, which required many vertical and horizontal curves. This feature also expedited the field work and made it possible to lay the pipe with inexperienced men and at a minimum cost.

Design and Location of Line—The pipe for this line is of the lock-bar type, with plain ends. The uniform thickness, for all sizes from 30 to 40 in., is ⅜ in. Three diameters of pipe are being used, as follows: There are 38,081 ft. of 40-in.; 12,381 ft. of 36-in. and 7881 ft. of 30-in. These reductions in size are made as the line nears its destination, and near the branches to the various manufacturing works. It was necessary to use riveted pipe in certain special sections for very sharp curves and for a riser which was required at a bridge.



CUSTER COUPLING SHOWING BUCKLE-PLATE SLEEVE AND RUBBER GASKETS

As the line passes through a hilly country, the vertical and horizontal curves are numerous; this required special beveling of the ends of the pipe so that they would fit tightly together. The grades and alignment were carefully worked out, and the pipe for curves were cut and match-marked for assembling. Where the curves are of large radius, the play allowed by the flexible joints used is sufficient to make the turn. The design of this coupling is shown in the sketch. The buckle-plate sleeve which abuts against the rubber gasket allows for an opening of from 1 in. to 1½ in. on the outside of curves, while still maintaining a gas-tight joint. By proper beveling a curve of 133-ft. radius was laid. To round this curve, which is shown in the illustration, six 17-ft. lengths, beveled 2¼ in. each end were used. The central angle of the curve is 44° 3 min. and the tangent length is 54 feet.

ROUNDING SHARP CURVE

Construction—Pipe was delivered at the site by rail, the standard length being 30 ft. It was loaded nine per car for 30-in., eight per car for 36-in., and five per car for 40-in. diameter. Delivery to the line was by teams, as it is has been found by experience that they cannot be equaled for this work, on account of the roughness of the country through which the lines generally run. The pipe can be loaded and unloaded by various means, but the general practice is to snub them down skids from the cars to the wagons, and from the wagons to the ground at the location. Accurate

TRENCH CUT BY EXCAVATOR —PIPE INSTALLED

placing is, of course, conducive to efficiency in laying, and this received particular attention. The pipes were distributed and strung out parallel to the line, as near as possible to the place they would finally occupy. However, where the line ran along a side hill, it was often necessary to lay them at right angles to the line to keep them from rolling. This caused extra expense in laying pipe.

Excavation—The nature of the soil along the line varies from heavy clay to hard rock. A large part of it is clay, and for such sections a specially designed trenching machine which digs a trench 54 in. wide is used. This width of trench will accommodate a 40-in. pipe. Where rock is encountered, a light revolving steam shovel of $\frac{3}{4}$-cu.yd. capacity, having a long dipper-handle is used. The trench is first drilled and blasted, and then cleaned out by means of the steam shovel. The general depth of the excavation runs from 6 to 8 ft., two feet of covering being considered advisable.

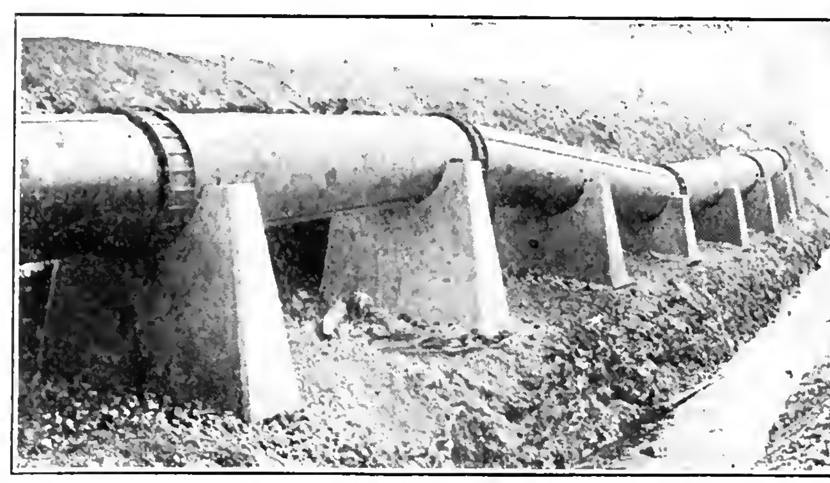
With the trenching machine 500 lin.ft. of trench, from 6 to 8 ft. deep, is excavated in 10 hours. The gang required for this work is an engineer, a fireman and 15 men. These are required to keep the buckets of the excavator from clogging, to keep the track clear for the track-laying tractive device, and to place planking where necessary. A view of the trench cut by the machine, with the pipe installed, is shown in the illustration. In some places, where the ground is unstable, it has been necessary to slope or sheet the sides of the trench.

Pipe Laying and Joining—After the delivery of the pipe, and upon the completion of the trench to the proper line and grade, pipe laying is accomplished by means of tripods supporting block and tackle operated by a winch, as shown in an illustration. After lowering the pipe into the trench and adjusting the joint, the back tripod is moved forward, while the forward tripod supports the end of the pipe until the insertion of the next length. In adjusting the joint the back ring is first put upon the pipe, and the rubber gasket, which fits snugly against the pipe, is snapped over it and pushed back to position in the ring groove. The buckle-plate sleeve is next inserted, after which the next length of pipe, with the forward ring and the rubber gasket already in place, is inserted in the sleeve. The ringbolts are now placed and the nuts tightened up temporarily. A $\frac{3}{8}$-in. clearance between the ends of the pipe is allowed for expansion. After temporary placing and tightening of the bolts, an auxiliary gang follows and completes this tightening, which presses the buckle-plate in against the rubber gasket, making an air-tight joint.

LOWERING THE PIPE WITH TRIPODS AND ADJUSTING THE JOINTS FOR TIGHTENING

One foreman and 30 to 35 men lay and completely connect up about 400 ft. of this gas-line per day, including an initial covering with about 1 ft. of earth. Inasmuch as there is no riveting, the work can all be done with ordinary labor under proper supervision.

As soon as a mile of pipe has been laid and the centers have been backfilled, it is subjected to what is known as a soap-and-water test. This consists of sealing the ends of the pipe and going over all field joints with soap and water, so that when the pipe is subjected to the required pressure of 50 lb. per square inch, soap bubbles will appear upon the surface, if there is leakage. The individual sections of pipe receive this test before leaving the shops. This is considered one of the severest tests that can be required of a gas line.



PIPE LAID UPON CONCRETE PIERS WITH 15-FOOT SPAN ALONG EMBANKMENT

Backfilling—Backfilling is accomplished by means of a dragline machine. With a gang of six men about 300 ft. per day is backfilled on the average. It is necessary to dress up the final surface by hand.

Work upon the 48,000-ft. line to the Duquesne and Edgar Thomson steel mills began Oct. 1, 1917, and was completed Aug. 31, 1918. The 12,000-ft. branch to the Homestead steel works is now being completed. The average gang employed upon the work has been 1000 men, who work in several gangs. In special cases the pipe was laid above ground on concrete piers with a span of about 15 ft., as shown in one of the illustrations. Being a gas line, it is unnecessary to keep it covered on account of frost.

The T. A. Gillespie Co., of New York is the contractor for the construction, and the lock-bar pipe is being furnished by the East Jersey Pipe Corporation.

Notes on the Design of a Single-Wall Cofferdam

Size and Location of Timber Wales and Braces and Size of Timber and Steel Sheeting Developed From Both Theoretic and Economic Considerations

By F. R. Sweeny
Engineer, The Foundation Co., Pittsburgh, Penn.

COFFERDAMS are too often built by rule-of-thumb methods, regardless of structural or economic requirements. The following analysis is offered as a practical and ready solution of the design of the most generally used type of cofferdam, the open pit in which the retained earth or water is held by vertical sheet-piles bearing against longitudinal wales and cross-braces. Such a coffer is shown in plan and cross-section in Fig. 1, which also gives the diagram of pressure,

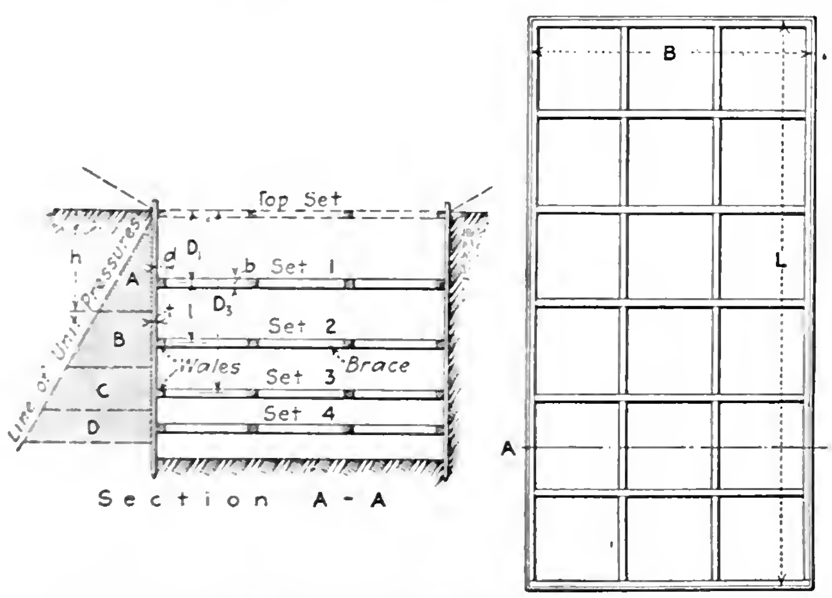


FIG. 1. PLAN SECTION AND OUTSIDE PRESSURE DIAGRAM OF SINGLE-WALL COFFERDAM

assuming that the horizontal unit pressure varies directly as the depth.

Let

w = Weight per cubic foot of material outside sheeting.

c = Ratio of horizontal to vertical pressures.

s = Span of wale in feet.

N = Number of rows of wales from surface (not counting top set).

D_1, D_2, D_N = Distance from surface to corresponding wale.

b = Width of wale as a beam.

d = Depth of wale as a beam.

l = Span of sheeting or distance between wales.

h = Depth from surface to any point.

W = Allowable load on wale of span s and section $b \times d$.

k = Safe unit stress in wale.

b' = Width of single sheeting.

In addition to the above assumptions, let areas A, B, C, and D be equal, which means that all wales are the same size. It follows from these assumptions that the top wale set will be theoretically of zero size, since it is supposed to carry no part of the load from area A. From practical considerations this set is always placed, but it will form no part of these discussions, since, by so doing, the conclusions will in no way be affected. This set is shown dotted.

The total load on N wales over one panel =

$$\frac{1}{2}wch^2s = NW \text{ or } N = \frac{wch^2s}{2W}$$

But since $W = \frac{kbd^2}{9s}$ then

$$N = \frac{4.5wch^2s^2}{kbd^2} \qquad (1)$$

$$h = \sqrt{\frac{kbd^2N}{4.5wcs^2}} \qquad (2)$$

Equating the moment of the total pressure area, to include N wales, to the sum of the moments of the wale reactions about the surface, we get the following expression,

$$NW \times \frac{2}{3}\sqrt{\frac{kbd^2N}{4.5wcs^2}} = WD_1 + WD_2 + \ldots + WD_N$$

Solving for D_N we get

$$D_N = \frac{2}{3}\sqrt{\frac{kbd^2N^3}{4.5wcs^2}} - (D_1 + D_2 + D_3 + \ldots + D_{(N-1)})$$

Substituting the value of $D_{(N-1)}$

$$D_N = 0.314\frac{d}{s}\sqrt{\frac{kb}{wc}}\left(\sqrt{N^3} - \sqrt{(N-1)^3}\right) \qquad (3)$$

Equation (3) expresses the law of wale spacing, but would be of little practical value to the engineer in this form, as it is too complex for ready calculation. We can reduce this, however, to a very handy diagram, Fig. 2, (see page 710) in which all the variables are taken care of except k, w and c. For the diagram some constant value is assigned to these variables and the cases in which they may differ from the values assigned are provided by means of a table of constants, which will be taken up later.

In the right-hand side of the diagram let the abscissas be N and the ordinates the depth D to the wale N. The third variable s is taken care of by constructing, in the left-hand diagram, a different vertical scale for each value of s. These scales will vary in length directly as the span, and so can be most easily laid off by drawing radial lines from the point of intersection of the surface line with the zero span line. Now solve the equation for s equal to 10 ft. for all values of N and timber sizes $b \times d$ and plot the curves as shown. The depths to the different wales will be found on the proper span line opposite the points where the vertical N lines intersect the wale curves.

For example, let us assume a cofferdam 25 ft. deep and 12 x 12-in. wales. The factors determining the wale size will be considered later. We will also assume a span length of 12 ft. Reading down the 12-ft. span line in the left-hand diagram opposite the successive points where the vertical "No. of wales" lines on the right intersect the 12 x 12-in. wale line, we get the following depths, 0, 5½, 9½, 12½, 15, 17, 18¾, 20⅓, 21¾, 23⅓, 24½.

It will be noticed in the diagram that the wales are numbered starting with the one at the surface. This would not be true in plotting from the formula, but for

practical reasons the numbers have been shifted to include this one.

Many cases will arise in which different values of k, w and c will be chosen. In order to meet these conditions a table of constants must be developed whereby the data as taken from the diagram may be modified to produce the correct results. The constant in Eq. (3) is represented by the expression

$$0.314\sqrt{\frac{k}{wc}}$$

Which for the diagram in Fig. 2 is

$$0.314\sqrt{\frac{1500}{62.5 \times 1}}$$

Therefore to obtain any other value for D_N with other values for k, w, and c, the expression will be

$$\frac{D_N \text{ (from diagram)}}{0.314\sqrt{\frac{1500}{62.5 \times 1}}} \times 0.314\sqrt{\frac{k}{wc}}$$

From which we get as the value of the constant by which we multiply the depths as taken from the diagram

$$\sqrt{\frac{k \times 62.5}{wc \times 1500}} \qquad (4)$$

The accompanying table is worked out for both level and surcharged conditions, the unit weights and constants c are taken from Peele's "Mining Engineers' Handbook," p. 2233. If we assume $k = 1000$ lb. per square inch and dry sand with level surface for the digging material, then the depths as found in the example previously worked out will be modified by multiplying by 1.24, giving the following depths, 0, 6.84, 11.78, 15.5, 16.61, 21.1, 23.3, and the next comes at the bottom, or 25.2.

Design of Sheeting—So far only the wales and struts have been considered, but as the pressure is transmitted to them through the sheeting, the relation between sheeting span to wale spacing must be determined and plotted on the diagram in order to determine the limiting thickness for each layout of wales.

From Fig. 2 the following relation holds:

$$\frac{whcl^2}{8} = \frac{kb't^2}{12 \times 6} \text{ or } t^2 = \frac{0.75wchl^2}{k} \qquad (5)$$

Let $l^2 = (D_{(N+1)} - D_N)^2$ and substituting the value of h from Eq. (2) into Eq. (5) and using Eq. (3)

$$s = \sqrt[3]{\frac{0.0349d^3}{t^2} \times \sqrt{\frac{b^3k}{wc}} \times \sqrt{N}\left[\sqrt{(N+1)^3} - 2\sqrt{N^3} + \sqrt{(N-1)^3}\right]^2} \qquad (6)$$

Solving this equation for the different values of t, bd and N with the same values for k, w and c as used for the wales, the sheeting lines can be plotted on the diagram (Fig. 2). These are shown at the left crossing the span lines.

It is important, at this point, to call attention to the fact that the sheeting thickness is determined by the span near the surface and *not at the bottom* as held by many. The reason for this becomes apparent from Fig. 2, whence it will be seen that, whereas the load on each wale and therefore each span of sheeting is constant, the span is greater at the surface—the bending moment being proportional to the span, in this case. Note that in Eq. (5) and (6) the sheeting spans l are not considered as continuous, this being in line with good practice, since it is difficult to tell very much about the strength of wooden sheeting after it has been driven the full depth of the cofferdam. In the case of steel sheeting, however, we can and do consider it continuous.

To make the diagram complete, lines have been added for Lackawanna steel sheeting, both for the $\frac{3}{8}$ x $12\frac{3}{4}$-in. straight web and $\frac{3}{8}$ x 14-in. arch web for 12 x 12-in. and 14 x 14-in. wales, the resisting moments of which have been taken from the manufacturer's catalog. It is interesting to note, by way of comparison, that, considering the wooden sheeting noncontinuous and the steel continuous, the straight web sheeting is approximately equivalent to 5-in. wooden sheeting and the arch web to something over 7 inches.

In determining the limiting sheeting thickness, in any case it must be borne in mind that this will be found in the diagram opposite the position of the wale, the minimum sheeting for the full depth being found opposite the second wale for reasons just stated; thus, the sheeting lines have been discontinued above this point.

In regard to the change in values of k, w and c as in the case of the wales, these functions bear the inverse relation to t that they bear to D, therefore the same constants will hold good, but, instead of multiplying, the thickness must be divided by them.

Economics of the Structure—In determining the value of the unit stress k, it is well to bear in mind that higher values than are used in permanent structures are permissible, since the matter of deflection is ordinarily of little moment, provided sufficient strength is developed, with a reasonable factor of safety. Thus, it is thought that, for ordinary uses, 1500 lb. is a good value.

The values of w and c are not so easily determined, being largely matters of mature judgment. In any event, it is important to look into the matter of possible saturation of the soil to the point where hydrostatic pressure will be developed and superimposed upon the earth pressure.

When we begin to look into the matter of the size and span of wales and braces, we see that quite a number of factors enter in, chief among which are (1) proper clearance for dredging and other work, (2) layout of the permanent structure within, (3) economic considerations.

Let us investigate, first of all, just when the most economical condition obtains and in connection therewith consider the other factors.

Nothing has been said, up to this point, about the size of braces, so it will be assumed that they are the same size as the wales, which is not theoretically correct, but the assumption suffices for this investigation, as will be seen further on.

From Fig. 1, the total ft. B.M. of timber =

$$\left[\frac{2LB}{s} + B + L\right]N\frac{bd}{12} + [L + B]2Ht$$

Substituting the value of N from Eq. 1

$$Ft.B.M. = \left[\left(\frac{2LB}{s} + B + L\right)\frac{0.375cwH^2s^2}{kd}\right] + [B + L]2Ht \qquad (7)$$

The expression in the first bracket represents the timber in the wales and braces and the second bracket the sheeting.

Our object now is to determine the conditions for minimum timber in Eq. 7. As will be seen, there are three variables s, d and t, and the last may be expressed in terms of the other two together with the breadth b.

The proper method of approach, from a mathematical point of view, would be to assume some values for b and d, differentiate BM. with regard to the span s, equate the result to zero and solve for s. The values so found will give us the most economical span for that particular value of b and d. Then assume s constant and do likewise for b and d. This procedure, however, leads into rather complex expressions, and so we will resort to graphical solution.

From Eq. 7 draw the curve for each size wale, assuming successive values for the span s. The values for the sheeting thickness will have to be taken from the diagram corresponding to the specific condition of span, etc. Such curves have been plotted in Fig. 3 for two different cofferdams of widely varying proportions of breadth B to length L, the first or upper set being almost square in plan, while the lower represents an elongated layout.

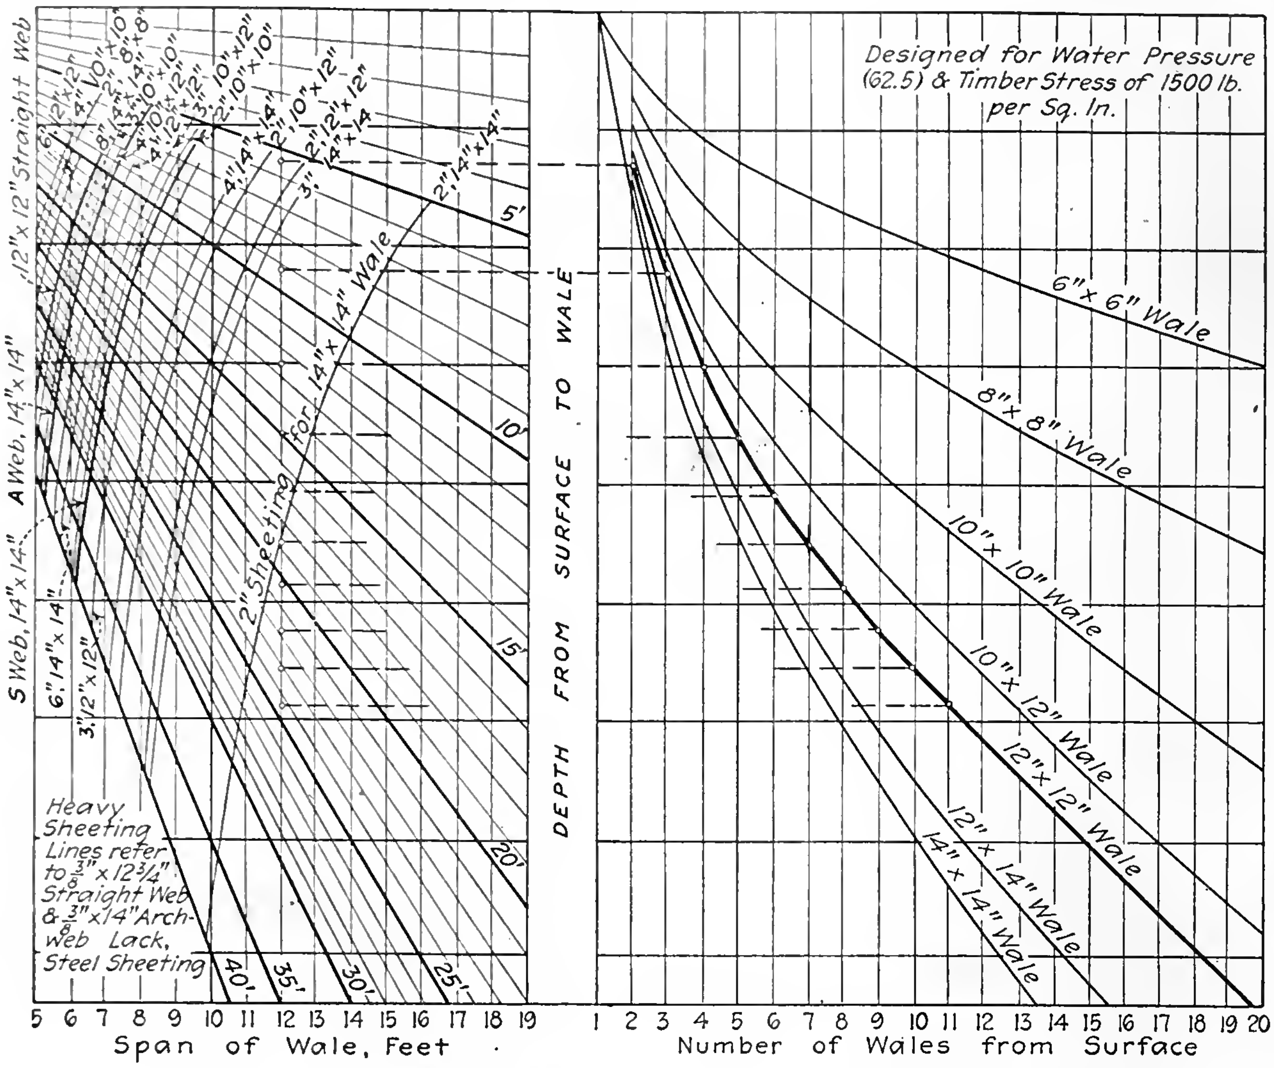

FIG. 2. DIAGRAM SHOWING WALE SPACING FOR COFFERDAM

The point of minimum timber is clearly shown for each case and forces the following conclusions: The quantity of timber varies, in general, with the size of wale and inversely as the span, the most economical span for each wale being roughly proportional to its size. The point of minimum timber varies very little for the two different sets of curves, comparing like wales. The necessity for maintaining the proper distance between braces for the dredging bucket and the handling of material fixes more or less exactly the span of the wale. This, in practice, is in the neighborhood of 10 ft., and for the most economical layout would call for a 12 x 12-in. wale.

It is sometimes expedient to arrange the bracing regardless of the above in order to meet certain construction conditions, the saving resulting from this offsetting the increased cost of timber. These conditions cannot be anticipated here other than to call attention to their possibility.

Where steel sheeting is used, we have rather different conditions. From the first part of Eq. (7), which expresses the quantity of timber in the wales and braces only, we see that the most economical condition obtains when the wale size is a maximum and the span a minimum. Thus, the proper solution would be to fix the minimum span permissible, taking into consideration the points heretofore brought out, and then select from the diagram the maximum wale size limited by the

MULTIPLY DEPTHS TO WALES AS FOUND IN DIAGRAM BY FOLLOWING CONSTANTS FOR THE CONDITIONS SHOWN

		Level Surface				Surcharged = ϕ			
	Unit		Fiber Stress				Fiber Stress		
Material	Wt.	C	1,000	1,500	2,000	C	1,000	1,500	2,000
Water	62.5	1.00	0.816	1.00	1.155	1.00	0.816	1.00	1.155
